ANT *TO* BALFE

ANT. The ants are one of several groups of social insects that belong to the order Hymenoptera.

General.—The more than 5,000 known species of ants, including the 600 species and subspecies in the U.S., are classified in seven subfamilies of the family Formicidae (*see* last section below). The ancestors of the ants are believed to have been solitary, fossorial wasps. Nothing is known about the initial evolution of ants, for no fossils antedating the Early Tertiary period (about 70,000,000 years ago) have yet been found. By that time the ants had reached the evolutionary level that they occupy today. Some of the beautifully preserved Baltic amber ants (Oligocene, about 35,000,000 years ago) are so nearly identical with present-day forms to suggest that the fossil and its living counterpart are of the same species.

Ants are heat-loving insects and only a few of them can endure cold climates. It follows that the greatest diversity of genera and species is found in the tropics and that the representation steadily decreases with an increase in distance north or south from the tropics. The number of ants in arctic or alpine regions is extremely low, and the group appears to be absent over great areas north of the Arctic circle.

The habits of ants vary endlessly, and it has been suggested that this may be partly due to their method of handling their larvae. Unlike the bees and the social wasps, ants do not enclose their larvae in individual cells. This gives them a flexibility in dealing with both larvae and nest that the other two groups lack. In extreme cases there will be no fixed nest, as in the Dorylinae, who carry the larvae with them during the nomadic phase. Despite their ability to utilize all sorts of nest sites most ants nest in the ground. Thus the majority of them still follow the pattern of their fossorial ancestors, who dug a burrow in the soil, provisioned it and laid their eggs therein.

Similarities and Differences.—It is difficult to give criteria by which any ant can be recognized because of the marked caste differences they show. In most ant colonies three castes (male, female and worker) are present, but in many of them the worker caste is polymorphic and has produced subcastes (major, medium, minor) that can be strikingly dissimilar. This structural diversity is often so great that it is impossible to associate the several castes of a species unless they are taken together in the nest.

Stages of Development.—All castes pass through the same stages of development: the egg hatches into a grublike larva; the larva, after a period of growth, changes into a pupa, and the pupa transforms into an adult. The structural differences that distinguish the castes first appear in the pupal stage, but other significant differences exist from the time the egg is laid. The eggs that develop into males are unfertilized, hence they contain only half as many chromosomes as does a fertilized egg; the characteristics of the male are determined by the chromosomal condition of the egg from which it develops. All fertilized eggs contain a double set of chromosomes, and all such eggs develop into females. The females are of two sorts: some are capable of mating, others are not. The queen, who can mate, is ordinarily winged at maturity. The worker, who cannot mate, never has wings and its simplified thorax is very different from that of the winged queen. Flight plays a large part in the mating reactions of most queen ants, but the lack of it does not explain the inability of the worker to mate. There are a number of ants in which the queen is wingless and has a worker type of thorax. These flightless queens can mate because they have a sac, the seminal receptacle, in which sperm cells are stored during copulation. In the worker this sac is vestigial or absent, hence the worker cannot store sperm. Although the worker cannot produce fertilized eggs it is not a sterile female, for it has functional ovaries and can lay unfertilized eggs that develop into males. But it is unable to lay fertilized eggs, which is the principal function of the queen. Each colony produces males and potential queens at certain times each year, usually in warm weather.

Establishing a Colony.—If a potential queen is to lay fertilized eggs, she must be inseminated, and, since most queens are winged, this ordinarily leads to a complicated set of responses known as the marriage flight. The virgin queen mates with a single male, who also is winged, and the two take off coupled together. During their flight the male transfers to the seminal receptacle of the queen all the sperm cells she will have for the rest of her life. Observations on queens in artificial nests have shown that this supply of sperm cells can last for at least 15 years. Since the only function of the male is to inseminate the queen, he is discarded at the end of the marriage flight and promptly dies. This leaves nest-founding entirely to the queen. Each of the many potential queens that becomes fertilized is capable of setting up (or taking

over) a nest of her own, provided she survives. The primary objective of the newly fertilized queen is to find a spot where she can safely raise her brood, although this is by no means all that is involved in nest-founding. Ants rarely move their nests after the colony has been established, hence a satisfactory nest site must not only provide immediate protection for the queen but also must later meet the requirements of the developing colony. When these requirements are exacting, the response of the female must be exact. Thus the queen of an arboreal species that can survive only in trees must seek out this environment at the time of nest-founding. It may, therefore, be said that the distribution and the environmental relationships of any species of ant represent the selective effect of the environment on the nest-founding responses of the female during the course of the species' evolution.

Soon after the marriage flight the queen's wings fall off or she pulls them off. The bulky wing muscles then begin to degenerate and are slowly converted into salivary secretions. At this time the queen's ovaries become functional and egg-laying begins. Later these eggs hatch into larvae, which must be fed. In primitive ants the queen will leave the nest at this time and forage for food to give to the larvae. In specialized ants the queen rarely behaves in this fashion. After she has selected a nest site she never leaves it. Thus her first larvae are fed on salivary secretions derived from the degenerating wing muscles. In this type of nest-founding the queen usually eats some of her own eggs. Those that survive transform into very small workers called minims. Once the minims have been produced the queen's greatest difficulty is over, for the minims leave the nest and forage for food and the colony is well on its way to successful establishment. The colony and its queen, who continues to lay eggs fertilized by the stored sperm of her dead mate, may survive for 10 or 15 years.

Trophallaxis.—It is important to understand why the queen tends the brood during nest-founding and why the workers do so after the nest has been established. Affection for the brood is not the reason, for the nest-founding queen normally eats some of her own eggs, and the workers, if prevented from foraging, will eat the brood rather than starve. The brood is tended because those who tend it wish to eat certain secretions that the larvae produce when fed. Food given the larvae is thus exchanged for edible secretions produced by the larvae. This food exchange is called trophallaxis, and it is the basis of ant society. Anything that affects trophallaxis is certain to produce drastic results in the life of the colony; many of the most remarkable habits of ants are measures that cover impaired trophallaxis.

When a great disparity exists between the size of the queen and that of the worker, the queen may be too large to tend her larvae. In the genus *Carebara* the queen may be more than 2,000 times as large as the minute larvae from which the tiny workers are produced. Just before the queen of *Carebara* begins her marriage flight a few workers lock their mandibles on her tarsal hairs. This response is often misdirected, for the workers will also seize the tarsal hairs of the male, and those who do are discarded with him when the marriage flight ends. But the queen's little passengers can tend her brood as soon as she starts to lay eggs. Without them there could be no nest-founding in *Carebara*, since trophallaxis between the queen and her larvae is mechanically impossible.

At the other extreme are the diminutive queens (*Formica*, *Bothriomyrmex*, etc.) whose limited wing musculature cannot furnish enough salivary secretion to bring through the first brood. These little queens may be smaller than their own workers and are not easily recognized as queens. This may help them gain entry into the host nest, for all such queens must have aid in raising their first brood and all depend upon the workers of some other species for this aid. To secure it the little queen must enter the host nest and remain in it until she has replaced her own nest odour with that of the host species. If she can avoid being killed during this period, which she often does by hiding, she will be accepted by the host workers, who will tend her brood. The intruding queen may then dispose of the rightful queen by violence (in *Bothriomyrmex* she climbs on the back of the rightful queen and slowly chews her victim's head off) or she may make herself so attractive to the host workers that they allow their own queen to die of neglect. As the intruder's offspring mature, a mixed colony results, but this is temporary since the host workers ultimately die. Here again this behaviour results from the inability of the diminutive queen to carry on trophallaxis with her larvae during nest-founding.

The most spectacular habits resulting from inability to perform trophallaxis are those of the so-called "slave-making" species in the genera *Polyergus*, *Harpagoxenus*, *Strongylognathus*, *Formica* and *Leptothorax*. These intruding queens are highly pugnacious and can force their way into the host nest. If the queen's entry is resisted she quickly kills any host workers who oppose her. Her ferocity at this time is astonishing, and the surviving host workers soon cease to combat her and try to save their brood. But the intruding queen appropriates all the brood that she can find and guards it so that the host workers cannot recover it. This brood contains pupae, some of which soon transform into host workers who accept the intruder as their queen. By this time the disorganization of the host nest is often so great that the host queen may die of neglect, but if she lives the intruding queen finally kills her and disposes of any hostile workers who still remain in the nest. These complex responses provide the intruding queen with host workers who will care for the brood that she is unable to tend. But the matter does not end here, for workers produced by such queens repeat in large part the nest-founding activities of their queen. At certain times they will force their way into a nest of the host species, kill any opponents that resist them and appropriate their brood. This brood is then carried back to the raider's own nest, where it transforms into workers of the host species. Such mixed colonies are often permanent, for new workers of the host continue to emerge from the brood brought back to the raider's nest. In *Polyergus* the mixed colony must be maintained, for the workers of *Polyergus* feed neither their larvae nor themselves, a deficiency that is rectified by the activities of the host workers. Here trophallaxis has totally broken down, for neither the queen nor the worker of *Polyergus* exchanges food with the larvae.

Liquid Food.—Much of the evolutionary advance that marks the higher groups of ants is attributable to one notable improvement in their trophallaxis—they have developed a method of feeding their larvae liquid food. If the larvae can only be given solid food, which is the primitive condition, many easily secured liquid foods (the nectar of flowers, the sugary honeydew secretions of aphids, the juices of fruits, etc.) cannot be used in trophallaxis. To feed the larvae liquid food the worker must make use of a

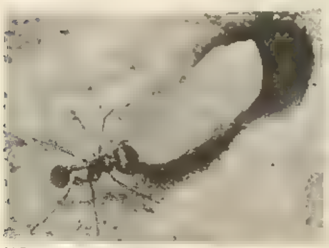
complex abdominal structure, the proventriculus. This combination valve and pump occurs at the posterior end of the crop. Liquid foods that enter the crop can be stored there indefinitely if the proventriculus is kept closed. Enough of this food to keep the worker alive can be admitted to the mid-gut if the proventriculus is briefly opened. Or, if the proventriculus performs its pumping function, part or all of the food in the crop can be forced back into the mouth. This is called regurgitation, and regurgitation is necessary for trophallaxis when liquid foods are employed. The regurgitated food can be fed not only to the larvae but also to any member of the colony. Experiments with liquid food containing tracers have shown that regurgitation may distribute such food to every adult member of the colony in three or four hours.

Food Storage in Repletes.—Certain ants that live in arid areas (*Myrmecocystus, Leptomyrmex* and a few species of *Camponotus*) take advantage of the storage function of the crop to produce a remarkable kind of worker called a replete. The prospective replete is fed large amounts of honeydew or other sugary liquids by the other workers. The storage of these liquids in the crop causes it to become so greatly distended that the abdominal sclerites are forced apart. The engorged replete finally has an abdomen about the size and shape of a large garden pea, made translucent and swollen to the bursting point by the distended crop full of honey. The repletes attach themselves to the ceilings of special chambers, for the enormous abdomen makes locomotion difficult, and supply liquid food by regurgitation as needed. Despite this remarkable adaptation many honey ants also store dead insects in their nests, for few ants are so stereotyped in their diet that they rely on a single kind of food.

ROSS E. HUTCHINS

FIG. 2.—HONEY ANT REPLETE (MYRMECOCYSTUS) HANGING FROM CEILING OF ANT CHAMBER

Ants as Nuisances.—A notable exception to the generalization that ants eat a varied diet is the fungus ant, of which the leaf cutters of the genus *Atta* are the most spectacular. These ants eat only a fungus that they raise in their nests. The workers cut pieces from leaves, bring them to the nest, chew them into a spongy compost and raise the fungus garden on it. Since the nests of *Atta* are usually populous, these ants may strip a small tree overnight, hence they are sometimes a pest to fruit growers. But in most cases they are no more than a nuisance, and this is true of most ants for these insects seldom cause extensive damage unless they are introduced into an area from a foreign source. If an ant is notably insectivorous, as are the army ants of the American tropics, it is usually regarded as beneficial despite the nuisance it causes. Instead of being a dreaded scourge these highly efficient insect exterminators are often welcomed by people who live where they occur. For the temporary inconvenience caused by the intrusion of a column of army ants into a house is outweighed by the fact that when the ants leave the house will be free from insects and other unwelcome arthropods.



AUTHENTICATED NEWS

FIG. 3.—AN ANT LIFTING A STONE, MANY TIMES ITS OWN WEIGHT, UP AND OUT OF ITS BURROW

Exterminating a Colony.—If an ant colony is to be exterminated the queen must be killed. Since she retires to the most obscure part of the nest when disturbed, the most lethal poisons (hydrocyanic acid gas, DDT and the nerve gas derivatives) may fail to reach her. A more certain method involves the use of poison bait, a method based on the fact that the queen receives more food than any individual worker. If the concentration of poison in the bait is correct (usually about 2% of some form of arsenic) it will not kill the foraging workers but will kill the queen when the workers feed it to her. The main difficulty with this method, aside from its slowness, is that no one bait will attract all ants equally well. But, since few ants that are nuisances refuse sugar baits, these generally prove effective if consistently used.

CLASSIFICATION

In the discussion of the subfamilies, the following definitions apply. The petiole is the slender, waistlike part that connects the thorax with the large, terminal gaster. Primary monomorphism is the primitive evolutionary condition of the worker caste in which all the workers are of the same size and not notably smaller than the queen. The next higher condition is polymorphism, in which the workers vary notably in size and often in structure as well. A fully developed polymorphic worker caste contains minors, medias and majors. If the medias drop out a dimorphic worker caste of minors and majors results. If both medias and majors drop out, the worker caste has reached a condition of secondary monomorphism, where all the workers are the same size but notably smaller than the queen. While it cannot be claimed that the worker caste invariably passes through these stages as evolution proceeds, enough species have done so to make the condition of the worker caste a reasonably good index of the degree of evolution.

The family Formicidae is made up of the following seven subfamilies:

Ponerinae.—Petiole of two segments, the second often not clearly set off from the gaster. Sting present and functional. Pupae usually enclosed in cocoons. Worker caste monomorphic (primary), rarely polymorphic. Uniformly carnivorous. Many of the larger ponerines have atrocious stings and use them freely. In areas where such ants occur the natives detest and fear them.

Cerapachyinae.—Petiole as in the ponerines. Sting present and functional. Pupae, where known, enclosed in cocoons. Worker caste monomorphic (primary). Carnivorous and living largely upon other ants whose nests they raid. A small and little-known subfamily that combines ponerine and doryline features.

Dorylinae.—Petiole of two segments, the second usually, but not always, clearly set off from the gaster. Sting present and functional. Pupae naked or enclosed in cocoons. Worker caste polymorphic or monomorphic (secondary?). Carnivorous and nomadic. The African "drivers" and the Neotropical "army ants" belong to this subfamily. The doryline queen always lacks wings and has a voluminous gaster capable of great distention during periods of active egg-laying.

Pseudomyrminae.—Petiole of two segments. Sting present and functional. Pupae never enclosed in cocoons. Worker caste monomorphic (primary). Omnivorous. Mainly arboreal although some species live in the hollow stems of sedges and grasses. Most members of this subfamily are slender, agile ants with large eyes. Some of the species are very pugnacious and sting severely.

Myrmicinae.—Petiole of two segments. Sting always present but not always functional. Pupae never enclosed in cocoons. Worker caste polymorphic, dimorphic or monomorphic (secondary). Widely diverse food preferences. In this subfamily there are harvesters, fungus growers, slave makers, thief ants, guest ants, arboreals and workerless parasites. One group of genera has become secondarily carnivorous and feeds entirely on collembola. This is the largest subfamily and most diverse one, both in structure and habits. It has produced a number of species that are regarded as pests. The "grease ants," "pavement ants" and "fire ants" belong to this subfamily.

Dolichoderinae.—Petiole of one segment. Sting vestigial, except in one genus. Pupae never enclosed in cocoons. Worker caste mainly monomorphic (secondary), occasionally polymorphic, rarely dimorphic. Omnivorous. These ants possess repugnatorial glands that produce a powerful odour that repels other ants. This subfamily is a highly successful one, although it lacks the great structural diversity of Myrmicinae. The habits of the Dolichoderinae are also rather uniform, but the group has produced

arboreal species, a genus that has repletes and one whose female is a temporary social parasite. The "Argentine ant" belongs to this subfamily.

Formicinae.—Petiole of one segment. Sting absent, the poison sac much modified. Pupae usually enclosed in cocoons. Worker caste polymorphic or monomorphic (secondary) or occasionally dimorphic. Omnivorous. This is the second largest subfamily. While it has produced a number of species whose structure is greatly modified, in the main the structure is rather uniform throughout the subfamily. Nevertheless this subfamily shows a considerable range of habits. There are species that produce repletes, slave makers, temporary social parasites and arboreal species with widely different habits. One group of arboreals makes a nest of leaves, which they "sew" together with silk produced by the larvae. An unusually large proportion of the species in this subfamily are able to tolerate cold climates. It follows that most people who live in north temperate areas derive their concept of ants from this subfamily. Often it is based on the "carpenter ant," which is a widespread and troublesome member of this group.

(W. S. CR.)

ANTA, in architecture, the slightly projecting pilaster strip at the extremity of a wall that flanks a porch or part of a porch. It is a masonry development from early wooden structural posts used, as in the Heraeum at Olympia, to reinforce the brick walls. The term is also used in modern work to describe any pilaster

(LEFT) FROM BUHLMANN, "CLASSIC AND RENAISSANCE ARCHITECTURE" (NEFF & HELBURN); (RIGHT) BY COURTESY OF THE ORIENTAL INSTITUTE

(LEFT) ANTA AND COLUMN, TEMPLE OF NIKE APTEROS, ATHENS; (RIGHT) ANTAE AND COLUMNS IN ANTIS, TEMPLE OF RAMESES III AT MEDINET HABU, EGYPT

whose detail resembles that of a true anta. Columns set between antae are termed "in antis." *See* GREEK ARCHITECTURE.

ANTALYA (ADALIA), an ancient seaport and capital of an *il* (province) of the same name on the southern coast of Turkey. Pop. (1960) 50,908. The walled city occupies the summit of a low cliff overlooking the harbour, which is protected by extensions of the fortifications. The modern town spreads westward along the cliff, with municipal buildings and gardens, a market and hotels. There are considerable remains of the Roman occupation, including "Hadrian's gate" in the north wall and a fragmentary temple of Diana. There are also Seljuk buildings, in one of which, a medrese with a fine minaret, is a museum. Antalya is accessible from the interior only by road from the railhead at Burdur (75 mi.) or from Mersin by the new coastal road. The harbour is suitable only for small coastal steamers. There is an airport 4¼ mi. from the town.

Founded in the 2nd century B.C. by Attalus II, king of Pergamum, the town was bequeathed by his family to the Romans. As the biblical Attaleia it was the port from which SS. Paul and Barnabas sailed to Antioch. In A.D. 135 Hadrian made it the capital of a senatorial province, Pamphylia. A Byzantine stronghold in the 10th century, it was taken by Kilij Arslan in 1207 and became the first Seljuk port on the Mediterranean. After the fall of the Rum sultanate, it changed hands many times, being successively occupied by the Mongols, the Karamanoglu, the Venetians and the Genoese. It was incorporated in the Ottoman empire in the 15th century.

ANTALYA *il*, containing two *kaza* (districts), consists mostly of a crescent-shaped coastal plain hemmed in by the Taurus mountains. Pop. (1960) 418,355. It has become a tourist area because it is easily accessible by motor road, and because of such well-known historical sites as Aspendus (*q.v.*) with its finely preserved Roman theatre, Perga (*q.v.*), Sillium, Side near Manavgat, excavated by Turkish archaeologists, and the picturesque Seljuk fortress and harbour at Alanya (Ala'iyya). In ancient times part of the modern Antalya was the district of Lycia (*q.v.*).

BIBLIOGRAPHY.—C. Lanckoronski, *Villes de Pamphylie et de Pisidie* (1890); R. M. Riefstahl, *Turkish Architecture in Southwestern Anatolia* (1931); S. Lloyd and D. S. Rice, *Alanya-Ala'iyya* (1959).

(S. H. LL.)

ANTANANARIVO (Fr. TANANARIVE), the capital of the Malagasy Republic (Madagascar) and the seat of the French high commissioner. It is centrally situated about 90 mi. from the island's eastern coast. The climate is tropical with a cool, dry season and a warm season that brings torrential rains. The average temperature is 65° F. The population increased rapidly during the 20th century. In 1901 there were 56,000 inhabitants and in 1960 the figure had grown to 247,917.

The town, formerly called Analamanga ("the blue forest"), stands on the highest of 12 hills in a mountainous region comprising Tananarive province (area 22,042 sq.mi.; pop. [1960 est.] 1,209,168), of which Antananarivo is the administrative seat. Avenues and flights of steps lead up the steeper hillslopes to a rocky ridge (4,694 ft.) which rises over 600 ft. above the fertile plains of the Ikopa to the west. High on this ridge is the rova or royal estate with its towered palaces built by the Imerina kings. Lower on the hillside, in the district off the Place Colbert, are the banks and administrative buildings, and lower still, at the level of the rice fields, is the commercial quarter. Public buildings include the French residency and the Anglican and Roman Catholic cathedrals. In addition to many missionary schools there are research institutes, an observatory and schools of law and medicine; the university has faculties of science and literature. Antananarivo is the distributing centre for an extensive rice-growing region. Its industries include tobacco and food processing, and factories produce leather goods, clothing and foodstuffs.

Air travel is of paramount importance. The airports at Ivato and Arivonimano are about 25 mi. and 38 mi. respectively from the town. Antananarivo is linked by rail with Tamatave (*q.v.*), the island's chief port, on the eastern coast and with Antsirabe to the south. Main roads from the north, south and east coasts converge at Antananarivo, the only road to the Mozambique channel being merely track for part of the way.

Founded in the 17th century, Antananarivo was for a long time the capital of the Hova chiefs, but it advanced in importance as those chiefs made themselves sovereigns of the greater part of Madagascar. In 1794, with the capture of the town by Andrianampoinimerina, prince of Ambohimanga, the town's precedence in Imerina (the central district) was established. The first Frenchmen penetrated to Antananarivo in 1777, and in 1832 arrived the French artisan Jean Laborde who introduced many industries. Both Protestant and Catholic missionaries began to settle there in the 1820s. Because of its politico-economic importance and its central position, Antananarivo was selected as its headquarters by the French command when it was set up in 1895. *See* also MALAGASY REPUBLIC. (J. AR.)

ANTARAH (ANTAR; Arab. 'ANTARAH IBN SHADDAD AL-'ABSI), Arab poet and warrior of the second half of the 6th century, famous both for his poetry and as a figure in Arabic legend, comparable with Hercules in Greek mythology or Samson in the Old

Testament. His father was of the tribe of 'Abs and his mother a Negro slave. He loved his cousin 'Abla, but his request for her hand was refused because, not being acknowledged by his father, he was regarded as a slave. He won his father's recognition when, as he relates in one of his poems, the 'Absites were attacked and a fierce engagement ensued in which Antarah refused to join, saying, "A slave does not know how to fight"; whereupon his father cried, "Charge, you are free!" Many of his exploits were performed in the war between the tribes of 'Abs and Dhobyan, which began over a contest of horses and was called after their names the war of Dahis and Ghabra. He died in extreme old age in a fight against the tribe of Tai. The most famous of his poems (which are chiefly concerned with fighting or with his love for 'Abla) is contained in the collection of pre-Islamic odes known as the *Mu'allaqat* (*q.v.*). The romance of his life, *Sirat 'Antar ibn Shaddad*, was long handed down by oral tradition and has grown to immense proportions. It recounts heroic deeds against great odds, the slaying of a lion by the tearing apart of its jaws and an adventurous excursion into Persia, where Khosrau II showed him favour.

Bibliography.—Edition of poems by Mohammed al-'Inani (1911) and by W. Ahlwardt in the *Diwan of the Six Ancient Arabic Poets* (1870). *Sirat 'Antar ibn Shaddad* was publ. in 32 vol. (1889–94); partial Eng. trans. by Terrick Hamilton, *'Antar, a Bedoueen Romance*, 4 vol. (1820); French trans. by L. M. Devic, *Les Aventures d'Antar* (1878), re-issued as *Poème héroique arabe* (1898). (E. S. Ah.)

ANTARCTICA, the continent lying concentrically about the geographic south pole. Antarctica increases in importance as it becomes better known, and it is also significant as an area of large-scale international co-operation.

This article is divided into the following sections:

I. GENERAL SURVEY

1. Location and Description.—Antarctica lies in unique isolation in the triangle formed by the southernmost extension of South America, Africa and Australia. The nearest oceanic approach to a neighbouring continent is about 600 mi. (970 km.) across Drake strait from Tierra del Fuego to the tip of the Antarctic peninsula (a recently accepted name after long disputes over priority of discovery during which the British previously called this peninsula Graham Land and Americans called it Palmer peninsula; Argentina named it San Martin and Chile, Tierra de O'Higgins). Surrounding the continent is the Southern (or Antarctic) ocean, which is merely the confluent portions of the Pacific, Atlantic and Indian oceans; it is notoriously the stormiest in the world, for there is nothing to break the force of the persistent west winds. Warmer tropical waters meet with cold antarctic waters in a remarkably permanent girdling line ranging between latitude 45° and 65° S. known as the Antarctic convergence. This line, which varies considerably with longitude but generally within and not more than a degree or two of latitude per year, establishes a boundary between subtemperate and subantarctic zones. South of the convergence the waters are characteristically ice-laden and abound with subpolar aquatic life. It is a feeding region for myriads of pelagic sea birds and is the location of Antarctica's principal industry—whaling.

The continent itself is essentially circular in form except for the Antarctic peninsula and the inward bights of the Ross and Weddell seas. The great mile-thick (average) layer of continental ice thins toward the coasts and discharges flat-topped icebergs into the surrounding seas from piedmont glaciers, ice tongues and shelf-ice systems (*see* also Glacier). Along the periphery of the continent are rugged mountain peaks left bare by the skirting and receding ice. Farther inland the rugged landscape is generally drowned by ice cover, although gentle rolling surfaces and crevassed regions in places reflect its hidden character. Seismic exploration of the great expanses of deep ice cover indicate vast lowlands and areas in which the land surface is depressed below sea level by the weight of thousands of feet of ice cover.

The continent is asymmetrically divided into two parts by the high upthrust Transantarctic mountain range exceeding 15,000 ft. (450 m.) elevation. This cordillera runs from Victoria Land on the New Zealand side toward Coats Land on the Atlantic side. Its central relationship with the Andean-type ranges of the Antarctic peninsula is still uncertain for lack of adequate exploration. The geological formations of this central range seem to bear little resemblance to the Andean type, however, and its flat-lying, uplifted sedimentary rocks are in part carboniferous. Extensive low quality bituminous coal outcrops to within 200–300 mi. (320–480 km.) of the south pole yield fossils which portray an earlier age when the continent was forested. Whether this former warmer climate was due to climatic change, polar wandering or continental drift is still a matter of conjecture and investigation.

West Antarctica, the lesser of the two major subdivisions of the continent, lies almost entirely within the western hemisphere, facing toward the Pacific ocean. Ice soundings have shown this region to be largely an ice-covered archipelago. Ice thickness between the islands ranges to 14,000 ft. (4,270 m.) with elevations 4,000–6,000 ft. (1,200–1,800 m.) above sea level. West Antarctica is bordered by the bights formed by the Ross and Weddell seas. Its most thoroughly studied regions include Marie Byrd Land and the Antarctic peninsula.

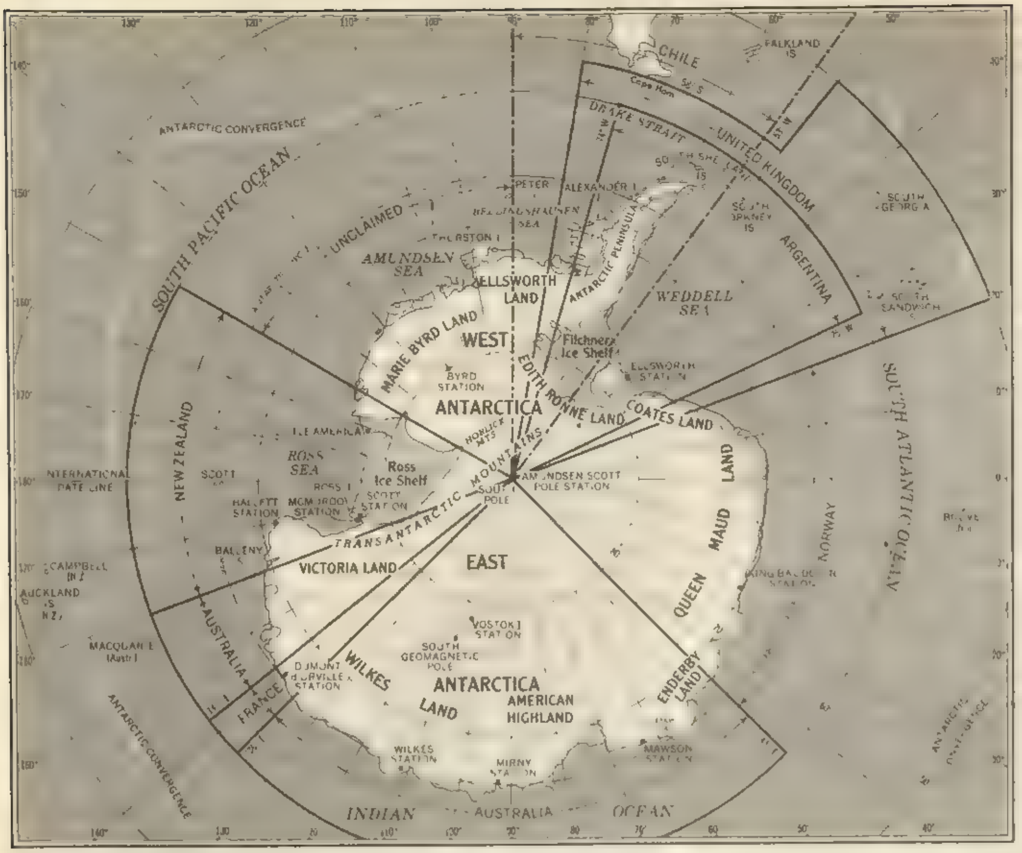
East Antarctica is nearly twice as large as west Antarctica and lies mostly within the eastern hemisphere. It appears to be more contiguously a continental mass. The subsurface beneath the ice is extremely rugged except west of Victoria Land, where it appears to be an extensive plain close to sea level; the internal ice cover forms nearly featureless domes rising to elevations above 1,200 ft. (370 m.).

Taken as a whole, with its lofty mountains and ice cover, Antarctica averages about 8,000 ft. (2,400 m.) in elevation, the highest of all the continents.

In sharp contrast to the lushness of sea life, the continent is virtually lifeless. Seals and birds that frequent the coasts and off-lying islands of Antarctica depend upon the sea for food and do not go farther inland than necessary to find breeding grounds. Aside from microscopic forms of life sparsely detectable in the snow and melt ponds, the only permanent life on the continent are lichens, mosses, fungi, a few grasses and two diminutive flowering plants. Tiny insectlike creatures find shelter and livelihood in the more luxuriant clumps of these hardy plants.

2. Knowledge of the Region.—Surrounding islands were discovered during the 18th century, but until 1820 sea ice prevented even the most daring navigators from seeing the continent itself. Positive recognition of a land mass of continental proportions was achieved in the mid-19th century, but, aside from relatively insignificant landings, the first fruitful efforts to explore the interior were initiated near the beginning of the 20th century.

Deep penetration by Ernest Shackleton, R. F. Scott and Roald Amundsen culminated in Amundsen's reaching the geographic south pole first in Dec. 1911, about 31 months after the north pole was reached by Robert E. Peary. It was not until the advent of new technical advances, such as aircraft, radios and aerial photog-



ANTARCTIC TERRITORIAL CLAIMS, TO REMAIN STATUS QUO UNDER THE TERMS OF A TREATY SIGNED BY 12 NATIONS ON DEC. 1, 1959. THE TREATY DEDICATES ANTARCTICA FOR PEACEFUL PURPOSES ONLY AND IN EFFECT INTERNATIONALIZES THE ENTIRE CONTINENT. (ICE SHELVES INDICATED BY LINED AREAS)

raphy, that the bulk of the coast lines and interior were first crudely mapped in the late pre-World War II period. Afterward much improved technical developments further stimulated interest in exploring the continent. Foremost was the appearance of powerful ice-breaking vessels which could shepherd cargo vessels through pack ice; the coast guard icebreaker "Northwind," leading vessel of the U.S. navy's Operation "Highjump" in 1947, was the first of its class to approach Antarctica. Advances in aircraft, aerial cameras, communications, weather forecasting and navigation systems and aids improved the ability to reach icebound coasts and inland areas denied to earlier expeditions.

A further significant change was in personnel. Early visitors to Antarctica, except for crews of sealing and whaling vessels, were unpaid volunteers who went exploring for adventure. In the post-World War II period there was an abundance of available military and civil service personnel, as well as excesses of usable military supplies, ships, aircraft, vehicles, foods and instruments, making logistics less difficult. All members of exploring parties became well-salaried employees; nominal leaders were administrators who themselves could not afford the time to remain in the antarctic during winter and in some cases not even in summer. Stations therefore became more like agencies receiving instructions from outside the continent. Nevertheless, the new approach provided longer continuity, and systematic long-range surveys and scientific programs became possible.

The continent can be said to be permanently inhabited since 1943, even though its personnel is usually exchanged annually. There was a marked increase of scientific exploration of Antarctica in the period 1955–60 associated with the International Geophysical year (*q.v.*) of 1957–58, and after IGY an intensive co-operative scientific program continued.

3. Ownership.—At the present time, by international agreement, the questions of antarctic ownership have been set aside in favour of unrestricted, co-operative, scientific exploration. However, previously the declared ownership of parts of Antarctica was confused and controversial among seven claimant nations. The United Kingdom, New Zealand, Australia, Norway and France agreed basically among themselves in laying claim to the bulk of the continent, with the notable small central portion of west Antarctica conceded to the United States. Norway's claims were the most modest, extending only to their coastal discoveries facing the Atlantic between longitude 45° E. through the Greenwich meridian westward to longitude 20° W.

France's claim of Terre Adélie, which is the smallest segment of any claimant, is bounded by longitudes 136° E. and 142° E. and flanked on either side by Australian claims. France also claims the Crozet and the Kerguelen islands in the southern Indian ocean.

The United Kingdom formerly made extensive claims but later bequeathed large portions of them to New Zealand and Australia. The New Zealand claim included the wedge-shaped segment extending from longitude 150° W. westward past the international date line to 160° E., bordering the Australian claims in Victoria Land. The French-split Australian claim was the largest national claim, extending from 160° E. westward to 45° E., adjoining the Norwegian claim. This region lying south of Australia and the Indian ocean included Wilkes Land, an important American discovery in 1847. Australia also claimed the Macquarie, Heard and other islands.

The British claim retained for itself the Falkland Islands dependencies (*see* FALKLAND ISLANDS AND BRITISH ANTARCTIC TERRITORY). It incorporated the best-known portion of Antarctica, the Antarctic peninsula and the numerous islands of the South Shetland and South Orkney archipelagos. South Georgia, whaling centre, was also included in the claim area, which extended in a segment to the pole lying between longitudes 20° and 80° W.

Argentina and Chile made conflicting claims of most of this same area, originally and primarily on the basis of the extension of their national longitudinal boundaries south to the pole, although after World War II both nations maintained many small military bases. The Argentine claims of 1943 extended between longitudes 25° and 74° W., including the Falkland Islands and South Georgia. The Chilean claims extended southward of latitude 60° S. between longitudes 53° and 90° W. British efforts to take the conflicting claims case to the International Court of Justice in 1947 and 1955 were ignored by Argentina and Chile.

Although U.S. citizens have laid claim to portions of Antarctica, the United States government has never made any formal claims nor recognized the assertion of other claimants. Other nations that have taken part in the exploration of Antarctica without laying claims include the U.S.S.R., Belgium, Japan, Germany, Sweden, Poland and South Africa.

In 1959 an Antarctic treaty extending for 30 years was signed by the 12 nations then actively exploring Antarctica and was later acceded to by other nations. Provisions of this treaty opened Antarctica to unrestricted scientific exploration in a spirit of international co-operation. Claimants agreed to place questions of sovereignty into abeyance during the period of the treaty without prejudice to their prior rights. They further agreed that no exploration during the treaty period would be used as a basis for future claims. If the treaty is extended indefinitely, Antarctica

may become the first international land in recent world history.

The bases of the various claims and the related question of the future status of Antarctica are discussed at greater length in following sections of this article. (PL. A. S.)

I. PHYSICAL CHARACTERISTICS

1. Meteorology.—The weather and climate of Antarctica are the result of several factors: (1) its location near the south pole of the earth, with the implied astronomical influences; (2) its great elevation, which intensifies the polar climate; (3) its perpetual snow cover with strong reflective and radiative characteristics that also intensify the polar climate; (4) its complete isolation from all other continents by a completely surrounding ocean of relatively warmer water.

The antarctic atmosphere has the same composition as that of the rest of the world, except that the principal variable gaseous component, water vapour, has only about one-tenth the concentration, on the average, that it has in middle latitudes. Excluding the Antarctic peninsula, the monthly mean temperature during the warmest month is around 32° F. (0° C.) in the coastal region and from −30° to −4° F. (−35° to −20° C.) in the interior; the water-vapour concentration can be no higher than about 5.5 and 0.5 gr. per cubic foot, respectively. In winter the coldest monthly mean temperature is from about −22° to −4° F. in the coastal region and from −94° to −40° F. in the interior; the water-vapour content is less than 0.9 and 0.002 gr. per cubic foot, respectively. The carbon dioxide content is between 310 and 315 parts per million, about the same as other parts of the world. Total atmospheric ozone is at a maximum in spring, usually November; limited dark-season data indicate minimum during the winter. Dust and other pollutants are practically unknown. Nuclear radiation, also, is at the very lowest levels observed on earth.

The total of the incoming direct and diffuse solar radiation reaches values of 75%–85% of the solar constant, depending upon the altitude of the station. The high values are partly due to the earth's being at perihelion—that point of its orbit nearest the sun—during the southern hemisphere summer, but the clear, dry atmosphere and high elevation of Antarctica are important factors. However, as much as 80%–90% of the incoming shortwave radiation is reflected by the snow surface. Only the upper three to five feet of the snow cover absorb appreciable amounts of the solar energy, and it is quickly lost again in the dark season because the dry atmosphere has little blanketing effect. Small amounts of cloud do not appreciably reduce the total amount of solar radiation reaching the surface, since there is a high multiple reflection caused by the snow surface and the underside of the clouds. In some cases this can even raise the total of the direct and diffuse radiation reaching the surface to a value higher than that of the solar constant; *i.e.,* the amount of radiation from the sun reaching the top of the atmosphere. The albedo, or reflectivity of the snow surface, varies from about 75% to 90%; values tend to be lowest after periods of ablation (*e.g.,* sublimation, melting, evaporation) and wind erosion and highest after fresh snowfall. The albedo has a seasonal as well as shorter period variation.

The isotherms of mean annual temperature over Antarctica generally approximate the terrain contours; the warmer temperatures are found near the low-lying coast and the coldest temperatures are found on the high plateau in the interior of east Antarctica, which averages between 2,600 and 3,600 ft. higher than the pole elevation of 9,200 ft. The annual mean on the plateau is about −68° F. and temperatures below −125° F. have been reported.

Although it is the world's coldest continent, Antarctica is not uniformly cold. Variations in the atmospheric circulation bring about considerable differences in temperature, both in time and in space. The minimum temperatures at one place do not always occur during the same month from one year to another, and places several hundred miles apart may be under completely different temperature regimes at the same time. A rise and fall of as much as 15° F. in the monthly mean temperature can take place in successive months during the winter. Under conditions of large-scale flow of air from the oceans to the continent, increased cloudiness will inhibit the loss of heat by radiation from the snow surface as well as increase the amount of heat radiated downward to the snow surface; a rise of as much as 25° F. in one day can occur.

In winter the main supply of heat to Antarctica is the warm air carried by the atmospheric currents. The first strong radiational cooling in winter causes an early winter temperature minimum, but the atmosphere reacts to this by changing its circulation so as to bring in the warmer air; finally, at the end of the winter, radiational cooling again becomes dominant and late winter minimum temperatures are noted, usually just before the return of the sun.

The cyclonic storms that move around Antarctica often pass across the west Antarctica highland, and even across the south pole, but only rarely over the higher plateau of east Antarctica. The exchange of air horizontally in the levels from about 8,000 to 15,000 ft. is such that a temperature fall of only about 15° F. is noted in the monthly mean values from summer to winter. The very lowest layers of the atmosphere lose heat by radiation and by contact with the snow surface. The result in these cases is inversion—that is, the temperature increases with height, and a gradient of 50° F. in 1,000 ft. is not uncommon.

Cyclones on the polar front attain great intensity and size; the air trajectory and the contrast between ocean and continental underlying surface are the principal factors in the development of weather at a given spot. The great storms and blizzards of long duration are related to deep disturbances extending in many cases from sea level to the tropopause (the boundary between the troposphere and the stratosphere), a height of about five miles in summer and six in winter. Storms of blowing snow accompany the disturbances and even persist for some hours after the passage of the initial storm. The shallow storms tend to move quickly around the periphery of the continent and are not related to the large-scale planetary waves in the atmosphere. The large storms move in arclike, clockwise trajectories, generally from the northwest to the southeast, and remain north of the coast line in most cases.

The high level of the continent, the strong gravitational outflow of the cold air in contact with the surface and the procession of storms act against the formation of large polar anticyclones, although the surface pressure in some localities has gone above 1,035 millibars. Some of the cold anticyclones have provided sufficient cold air, both from west Antarctica and from east Antarctica, to reach other southern hemisphere continents, although much modified by overwater trajectories of several thousand miles.

The jet stream, the core of winds of maximum velocity, found usually just below the tropopause and in regions of maximum horizontal temperature gradient, tends to broaden its latitudinal extent and strength in winter and tends to narrow and weaken in summer. Surface winds frequently attain speeds of 100 m.p.h. or more during the passage of storms along the coast of east Antarctica. The steep slope of the continent accentuates the geostrophic component of the wind in these cases; along low-lying coast lines, the maximum force of the wind is usually less.

The extension of the "effective" continent as much as six degrees of latitude farther north of its summer coast line comes about through the freezing of the surface layers of the ocean in winter. This inhibits the vertical exchange of heat between ocean and atmosphere and also provides a longer continental trajectory for the air of oceanic origin that reaches the continent. This is one reason for lower average cloudiness in winter than in summer.

In the spring and early summer great changes take place in the stratosphere. The circulation that was strongly cyclonic, with westerly winds averaging as much as 100 m.p.h., changes abruptly. In the free atmosphere at altitudes of about 12 mi. and higher, warming of as much as 70° F. takes place between early October and November, and easterly winds generally prevail. Much of this warming appears to be due to the transport of warm air from lower latitudes and to adiabatic heating—that is, an increase in air temperature as a consequence of internal processes of contraction caused by sinking motions over the continent; it is only partly caused by absorption of solar radiation in the atmosphere. During this period there is a sharp rise in surface pressure from the late wintertime minima that are noted almost everywhere over Antarctica to the summertime maxima. Great masses of air are transported and as much as 150,000,000 tons of air are lost or gained

over Antarctica from one month to another. Water-vapour condensation not only adds to the snow cover but also contributes about 14% of the net heat energy transported by the atmosphere. It is estimated that between five and eight inches of water equivalent is deposited in the form of snow over Antarctica in one year, on the average. The coastal regions have up to ten or more times the two inches snowfall deposited on the interior. If there were no outflow of this snow, or no loss in any other way, it would have taken from 9,000 to 15,000 years to deposit the 5,750,000 cubic miles of ice that is currently thought to cover the continent.

(M. J. Ru.)

2. Geology.—The geology of Antarctica is imperfectly known, as would be expected in a continent not fully explored and whose exposed bedrock amounts to less than 1% of the continent's surface. However, in a general way Antarctica can be divided into east Antarctica, which lies south of Australia and Africa, and west Antarctica, which lies south of South America. The dividing line between these two areas, the Transantarctic mountains, lies along the west side of the Ross sea and Ross ice shelf and extends north of the Horlick mountains to the Weddell sea.

East Antarctica was considered a shield area of igneous and metamorphic basement rocks of Precambrian (?) Age partly overlain by sedimentary rocks of Paleozoic to Mesozoic Age. This shield is bounded on the west side of the Ross sea and Ross ice shelf by the block faulted and folded Transantarctic mountains. In the interior, ice about 9,000 ft. (2,740 m.) thick rises to altitudes of 7,000 to 12,000 ft. and caps the bedrock. The bedrock is below sea level in many places.

Basement rocks in Victoria Land consist of granitic gneiss, mica schist, granulite and crystalline limestone which is intruded by granite containing veins of aplite and pegmatite. Overlying these rocks and extending at least to the Horlick mountains are flat-lying sedimentary rocks that consist of limestone of Cambrian (?) Age, and the Beacon group, consisting of quartz sandstone, arkose, conglomerate, shale, limestone and coal of Devonian (?) to Triassic (?) Age. These sedimentary rocks are intruded by diabase sills and dikes and cut by faults. Volcanic rocks at Mt. Discovery and at Mt. Erebus on Ross Island (the only continuously active volcano in Antarctica) are the youngest rocks in the area. Volcanic rocks also are found on offshore islands and in the northern part of Victoria Land in the vicinity of Cape Adare, where occur slates and graywackes of the Robertson bay group, of possible Early Paleozoic Age. Basement rocks similar to those in Victoria Land are exposed in some places along the coast of Wilkes Land.

From Wilkes Land to Enderby Land the basement is composed of quartzite, hornfels, gneiss, aplite, pegmatite, gabbro, norite, pyroxenite and hypersthenite of Precambrian (?) Age. Hypersthene granite, and diabase and basalt intrude part of these rocks. Southeast of Mawson, flat-lying arkosic sandstones and grits with

pebble beds and coal of Permian (?) Age are tentatively correlated with the Beacon group of Victoria Land. Slates, graywackes and volcanic rocks are exposed along the coast farther west.

West Antarctica has mountains jutting through an icecap that is thicker in places (over 14,000 ft. [4,270 m.]) but also generally lower in elevation than the plateau of east Antarctica.

Andean folding and volcanism can be traced southward from Cape Horn to the Scotia arc and Antarctic peninsula, where plutonic rocks are flanked on the west and north by a volcanic belt along the Scotia arc and on the east by sedimentary rocks. Conglomerates, sandstones and slates containing fossils of Jurassic Age occur on the east side of the Antarctic peninsula, and similar rocks and limestone are along the east side of Alexander I Island. Volcanic rocks have invaded the sedimentary sequence. Islands at the northeastern end of the Antarctic peninsula contain conglomerates and sandstones of the Snow Hill group of Cretaceous Age, which are overlain unconformably by conglomerates and sandstones of the Seymour Island group of Eocene to Miocene Age.

In Marie Byrd Land quartzites and slates about 15,000 ft. thick in the Edsel Ford ranges and the Rockefeller mountains are intruded by granite, granodiorite, quartz monzonite and recent volcanic rocks. Samples collected in the Executive Committee range and south of the Kohler range indicate that those mountains are of volcanic origin, whereas low-grade metamorphic rocks have been found in the foothills of the Sentinel mountains. Diorite is exposed in a part of Thurston Island but most of the island has been inadequately explored.

Geologists have thought that a broad ice-filled channel exists between the Ross and Weddell seas. However, new data indicate that a ridge of bedrock from the Sentinel mountains to the Transantarctic mountains crosses the supposed channel, and, instead, a deep trough may exist between the Bellingshausen and the Ross seas.

No minerals have been found in economic concentrations, but those of potential value include atacamite, azurite, beryl, bornite, cassiterite, chalcopyrite, chromite, fluorite, galena, gold, graphite, hematite, magnetite, malachite, manganese minerals, molybdenite, monazite, sphalerite, stibnite and uranium minerals.

Coal has been found near Mawson and in many places in the Beacon group from Coats Land, the Horlick mountains, Queen Maud range, Beardmore glacier region and northward into Victoria Land. The coal ranges from lignite to anthracite in grade and is generally in seams only a few inches thick, but one seam eight-feet thick was found near the top of Beardmore glacier by Shackleton's party in 1908. No petroleum has been discovered but it is conceivable that some may be in sedimentary rocks. (A. R. TA.)

3. Southern Ocean.—The Southern, or Antarctic, ocean forms the principal connecting link between the other major subdivisions of the world ocean (*see* OCEAN AND OCEANOGRAPHY). Although its northern limit has to be set quite arbitrarily and therefore has been characterized in various ways, it is convenient to follow the practice of the British admiralty and to define the Southern ocean as all the waters south of latitude 55° S. It thus has a total area, up to ice shelf edges, of 12,451,000 sq.mi. (32,248,000 sq.km.), with an average depth of 12,240 ft. (3,701 m.). Of this total area 5,643,000 sq.mi. is part of the Pacific ocean, 3,180,000 sq.mi. is part of the Atlantic ocean and 3,628,000 sq.mi. is part of the Indian ocean.

An appreciable additional portion of the Southern ocean is overlain by floating ice shelves and hence is commonly included in the area assigned to antarctic land. The Ross ice shelf covers about 160,000 sq.mi. of ocean, and the Filchner ice shelf and the extensive ice shelves off Marie Byrd Land, Queen Maud Land and elsewhere bring the total to about 360,000 sq.mi. Even inland from the ice shelves, Antarctica cannot be considered wholly as dry land, since measurements made during the International Geophysical year of 1957–58 showed that a large portion of the interior (possibly as much as a quarter) consists of ice of a thickness greater than its height above sea level. Thus, much of the "continent" is an island archipelago with glacier ice extending to the bottom of a former shallow ocean area.

The great circle routes between Cape Town and Melbourne, and from Australia or New Zealand to the North Atlantic via Cape Horn, penetrate deep into the Southern ocean. The use of the Suez and Panama canals has greatly reduced the shipping in southern waters, and many parts of the Antarctic are regularly visited now only by whalers, research ships and expedition vessels.

Seas and Islands.—The narrowest part of the Southern ocean, the strait between South America and the Antarctic peninsula, is known as Drake strait or Drake passage. The sea to the east, bounded by South Georgia and the Falkland, South Sandwich, South Orkney and South Shetland islands, is the Scotia sea. The Weddell sea is the area south of the Scotia sea from the Antarctic peninsula east to Cape Norvegia in 12° W. Cape Adare in 170° 15′ E. and Cape Colbeck in 158° 10′ W. mark the extremities of the Ross sea. The Amundsen sea is the bight between Cape Dart in 123° W. and Cape Flying Fish in 101° W. The Bellingshausen sea extends from Cape Flying Fish to the Antarctic peninsula.

There are few oceanic islands in the antarctic. The Scotia ridge trends east from Tierra del Fuego and then loops south and west to join the Antarctic peninsula. Its elevated portions form South Georgia (which lies just north of 55° S.), the Clerke rocks (about 40 mi. to the southeast), the South Sandwich Islands (a chain of volcanoes, some still active) and the South Orkneys. Bishop and Clark islands are a group of rocks in 158° E., outliers of Macquarie Island in 54° 45′ S. The Balleny Islands are an ice-covered volcanic chain in 67° S., 164 ° E. Scott Island, in 67° 24′ S., 179° 55′ E., is less than 100 mi. from the intersection of the Antarctic circle with the international date line. Peter I Island is a glacier-covered extinct volcano rising nearly 4,000 ft. above sea level in 68° 50′ S., 90° 35′ W.

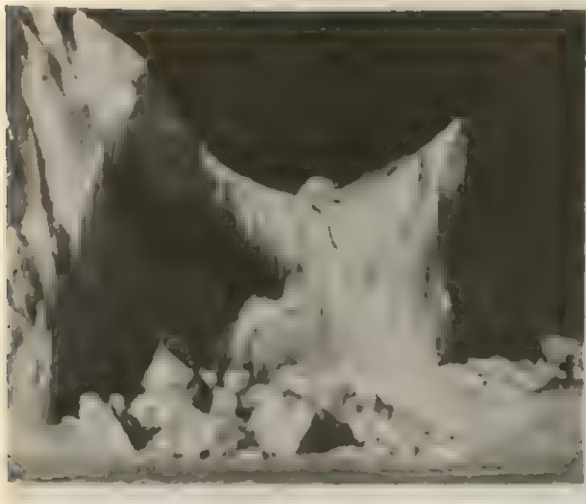
The principal islands of the continental shelf areas of the Southern ocean are Cape Horn and the neighbouring islands off Tierra del Fuego, and the South Shetlands and numerous other islands off the Antarctic peninsula. Alexander I Island (16,700 sq.mi.), in the eastern Bellingshausen sea, is the largest island south of 55° S. discovered by 1960. It is joined to the mainland by an ice shelf. Several islands have been identified beneath the Ross sea ice shelf.

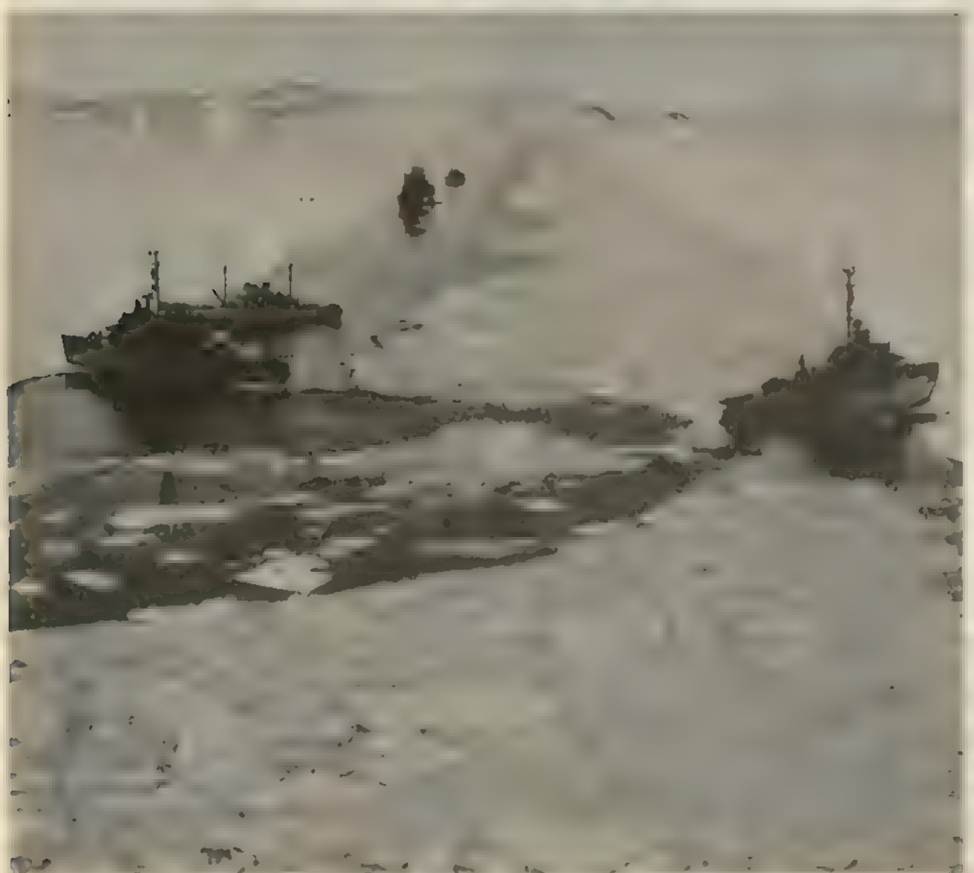
Ocean Floor.—The continental shelves surrounding Antarctica are to a large extent covered with ice shelves. Seaward of the ice shelf edges the continental shelves are mostly at a depth of 1,200 to 1,800 ft. They are widest in the western portion of the Weddell sea and in the southern Ross, Amundsen and Bellingshausen seas, with a maximum width of more than 300 mi. Elsewhere, as off Queen Maud Land, the continental shelf is virtually lacking. The sediments of the continental shelves are a random mixture of fine to coarse fragments of the continental rocks.

The deeper waters of the Southern ocean are characterized by four deep basins with soundings mainly from 15,000 to 18,000 ft., separated by ridges with depths of less than 12,000 ft. The largest of these basins lies between the Scotia ridge and a ridge running north and south through the middle of the Indian ocean (the mid-Atlantic ridge ends at the northern limit of the Antarctic ocean). It includes the Meteor Deep, a trench with a maximum sounding of 27,108 ft., just east of the South Sandwich chain; elsewhere its greatest depth does not exceed 19,500 ft. Between the mid-Indian ridge and a ridge running south from Tasmania is a smaller basin with a greatest depth of about 16,000 ft.; farther east a basin having a greatest depth of about 19,000 ft. about midway between New Zealand and Victoria Land is separated from the fourth basin by a ridge that runs northeast across the Pacific from Victoria Land. North of the Amundsen and Bellingshausen seas, this basin has a maximum depth of about 18,000 ft.

The pelagic sediments of the Antarctic ocean are composed chiefly of diatomaceous oozes, with an admixture of glacial clays, particularly north of the Weddell sea. These grade into the globigerina ooze of the central Pacific and into red clay closer to South America.

Tides and Currents.—There is a fairly uniform progression of the tidal wave from east to west around Antarctica. The tides are mainly diurnal, but mixed tides exist south of the Indian ocean along the western part of Wilkes Land and on the other side of the continent on the northern part of the Antarctic peninsula and the off-lying islands. Tidal ranges are moderate, mostly less





THE CHURCH BERG AND GROTTO (TOP LEFT) AND THE CASTLE BERG (TOP RIGHT): IMMENSE ICEBERGS CREATED FROM FLOATING CONTINENTAL SHELF ICE. (BOTTOM) ICEBREAKERS CLEARING A PATH THROUGH FLOATING SEA ICE NEAR LITTLE AMERICA

than five feet except at the northeastern tip of the Antarctic peninsula, where they may reach eight feet

The principal surface circulation of the Antarctic is part of the west wind drift, with a current of generally less than a knot setting easterly around the continent South of the Antarctic divergence which, except in the Weddell and Ross seas, is about 250 mi from the continent, there is a surface flow to the west. This current is best developed in the Weddell sea where it sweeps clockwise against the Antarctic peninsula

Water Masses and Deep Circulation.—The Antarctic divergence which exists around most of Antarctica, marks roughly the boundary between the prevailing westerly winds and the easterly and northeasterly winds that blow off the continent. About 600 mi northward is the Antarctic convergence, the position of which varies greatly with longitude, depending on the configuration of the coastal boundaries and the bottom topography. The surface waters south of the Antarctic convergence are colder than [illegible] F. in winter, except where the convergence reaches its farthest northerly limits. North of the Antarctic divergence there is a summer increase of about 5° F. in water surface temperature but farther south most of the summer heat is used to melt pack ice, and water of 30° F. or colder still surrounds the continent. This belt of cold water undergoes an increase in salinity and hence in density during the winter as the pack ice freezes, and it sinks to great depths all around the continent, especially off the Weddell sea. Deep water is forced to the surface by this process. At the Antarctic convergence cold surface water sinks beneath the subantarctic waters to the north This Antarctic intermediate water can be traced as far north in the Atlantic as 20° N. The surface salinities in the Antarctic are close to $34^0/_{00}$, except in the vicinity of melting ice, where they may be as low as $32^0/_{00}$. The deep convection of the Antarctic ocean is the main mechanism preventing stagnation in the deeper waters of the oceans to the north

The Barrier.—A unique phenomenon of Antarctica is the floating shelf ice, which is a derivative of the inland ice sheet When Capt. J. Clark Ross in 1841 first penetrated the pack ice into the Ross sea, he sailed due south until he was brought up in about 77° S. by the ice front of the greatest of these shelves, from 50 to 200 ft. high, barring his way to the south. The Ross ice shelf, as it is called, is the largest of these floating ice shelves but is typical of many others in the Antarctic. It is roughly the size of France and consists of a sheet of ice varying from [illegible] to [illegible] ft. or more in thickness, the outer end being open to the ocean and the inner end held fast to the continent by the glaciers, which act as feeders and by being anchored on shoals close to the actual coast. Its surface is smooth and it forms the easiest approach to the pole itself, since it reaches to within 300 mi of it. The tabular icebergs of the southern hemisphere, with their flat tops, stratified appearance and immense size (up to 90 mi in length of side) are derived from this shelf ice

The Sea Ice.—The sea ice itself is comparatively temporary It begins to form in sheltered bays as early as the end of January and by the beginning of March any ship is liable to be frozen in unless its harbour is a windy one. There are large variations from

year to year in the area of sea solidly frozen over, since strong winds, and such are very frequent, will prevent sea ice from forming or will blow out any that is not of considerable thickness. In sheltered bays the ice will continue to increase in thickness until October or November, by which time it will be any thickness up to seven feet. This will begin to break up and float northward from the beginning of December onward, but the innermost bays may not lose their ice until late in February, or occasionally not at all for two years or more in succession. The belt of pack ice which rings the continent is made up of the ice from this summer breakup. (J. L.)

4. Animal Life.—*Birds.*—Bird life of Antarctica is essentially marine, and, in keeping with general characteristics of the plant and animal life of cold oceans, it is poor in number of species but relatively rich in number of individuals. The birds of the region may be generally divided into those species inhabiting the islands within the subantarctic, some of which are within the Antarctic convergence, and those found on islands within the Antarctic circle and along the continent.

Within the Antarctic circle the emperor penguin (*Aptenodytes forsteri*), the Adélie penguin (*Pygoscelis adeliae*), the snow petrel (*Pagodroma nivea*) and the south polar skua (*Catharacta maccormicki*) are circumpolar in distribution and might be considered truly indigenous to the area. The emperor penguin, following the end of its winter breeding season, spends the summer no farther north than the edge of the pack ice. Conversely, the Adélie penguin nests on the islands and on the mainland of the continent during the summer and spends the winter within the pack ice. The south polar skua has the distinction of being the world's most southerly bird in its distribution. It has been observed within 80 mi. of the geographic south pole.

The emperor penguin is the most truly antarctic of all birds and is distinctive from other polar species in that it begins nesting in the winter. Unlike the Adélie penguin which has a fixed nest site that it returns to annually, the emperor penguin has no nest and merely carries the egg on top of its feet. It has no territorialism, and most of the rookeries are located on sea ice adjacent to the continent.

Prior to the IGY six emperor penguin rookeries had been located in Antarctica. These known rookeries included Cape Crozier in the McMurdo sound area at longitude 169° E., the first ever discovered; the Dion Islet rookery off the west coast of the Antarctic peninsula, south of Adelaide Island, where the British conducted the first detailed studies of the species; a rookery near Gaussberg in Kaiser Wilhelm II Land at longitude 89° E., reported by the Germans; the Point Géologie rookery in Adélie Land at longitude 140° E., which was studied by the French; the Haswell Islet rookery at longitude 92° E., discovered by Mawson in 1915; and a rookery at Taylor glacier on Mac-Robertson Coast at longitude 61° E., reported by the Australians in 1955. Known population figures for all these rookeries totaled less than 40,000 birds.

The Cape Crozier rookery, found in 1902 by members of the British National Antarctic expedition, was revisited by New Zealand scientists in Sept. 1957. It had shifted position somewhat from its original location on the sea ice and had about 1,000 adult birds, approximately five times the estimated population 50 years earlier.

During the IGY five new emperor penguin rookeries were discovered by the Australians, bringing to six the known number between longitudes 55° E. and 80° E. Two other rookeries were found in the Weddell sea area at Halley bay and Gould bay, numbering 21,000 and 8,000 birds respectively. These discoveries confirmed earlier reports of the presence of breeding birds.

Another large emperor penguin nesting area was discovered from a helicopter by United States personnel in Dec. 1958. Located approximately 250 mi. N. of McMurdo sound at latitude 73° S., longitude 169° E., between Coulman Island and Lady Newnes ice shelf, the rookery contained an estimated 33,000 breeding pairs. By 1960 known emperor penguin rookeries numbered 14 with an estimated population of more than 150,000. (*See* also PENGUIN.)

Additional bird species either nest on the islands and coasts of Antarctica or spend much of their time within this zone, and can be considered circumpolar in distribution. These include the giant petrel (*Macronectes giganteus*); silver-gray fulmar (*Priocella antarctica*), which except for the snow petrel is the commonest bird in the pack ice throughout the whole circumpolar belt; Cape pigeon (*Daption capensis*); antarctic petrel (*Thalassoica antarctica*); Wilson's petrel (*Oceanites oceanicus*); antarctic whalebird (*Pachyptila desolata*); antarctic tern (*Sterna vittata*); antarctic blue-eyed shag (*Phalacrocorax atriceps bransfieldensis*); and the kelp gull (*Larus dominicanus*). Other species will come within the zone at times but only about 32 species of birds penetrate beyond latitude 60° S. and most of these are subantarctic rather than polar wanderers. One of these, the arctic tern (*Sterna paradisea*), migrates from its nesting grounds in the arctic to the antarctic.

Mammals.—The antarctic seas are rich in marine mammals, particularly seals and whales, and whaling constitutes the only industry in the whole antarctic region. This industry is controlled, in part, through action of the International Whaling commission, organized in 1946. About 70% of the annual world catch of whales is taken in the antarctic. The species of most importance belong to two suborders, the Odontoceti (toothed whales) and the Mysticeti (whalebone whales). The whalebone, or baleen, whales, instead of having teeth, have a straining mechanism which enables them to feed on small marine organisms. The antarctic baleen whales of greatest industrial importance include the fin, sei, humpback and blue, the last mentioned being the largest of all whales. The sperm whale is the most important of the toothed whales. Fin

BIRDLIFE IN ANTARCTICA

(Above) Skua in flight, one of the world's most southerly birds; (left) emperor penguin, the only Antarctic bird that breeds in winter; (below) Adélie penguin, one of the few species native to Antarctica

whales, which form about 50% of the world catch, constitute about 70% of the total antarctic catch of all species. The more common smaller whales in antarctic waters, which are not usually taken commercially, include the killer whales. (*See* also WHALE; WHALING.)

Whereas mammal life in the arctic is closely related to forms found within the adjacent temperate belt, much of the similar life in the antarctic is largely endemic. This distinctive character is exemplified in the four well-marked genera of truly antarctic seals, which are unusual in that they show remarkably diverse structure correlated with no less distinct habits.

The crabeater seal (*Lobodon carcinophagus*) lives in the pack ice during winter and summer and is circumpolar in the antarctic but occasionally reaches subantarctic latitudes. It appears to be semimigratory, is gregarious and is the commonest seal in those waters. It lives almost exclusively on the pelagic shrimp *Euphausia superba*.

The Weddell seal (*Leptonychotes weddelli*) is more southern in distribution than the crabeater seal, and its range is confined more to the fast ice along the coasts throughout the year. It is gregarious, occurs in considerable numbers in parts of its range, is circumpolar, and occasionally reaches subantarctic latitudes. It feeds on large fish up to 50 in. in length, which are obtained by diving to depths of 1,400 ft.

The circumpolar Ross seal (*Ommatophoca rossi*) is the rarest of the four polar species. It inhabits the pack-ice belt, is solitary in its habits although a group of 10 were seen in the Ross sea, and appears to feed on fish and cephalopods.

The leopard seal (*Hydrurga leptonyx*) has a rather broad latitudinal range and is found from the shores of the antarctic continent northward to parts of the temperate zone. It is semimigratory, solitary in its habits and relatively widespread, but scarce. This aggressive seal preys on other seals and penguins as well as on fish and cephalopods.

The elephant seal (*Mirounga leonina*) normally breeds on the subantarctic islands but is occasionally found in antarctic waters. Several rookeries of immature seals have been found on the edge of the continent in Indian ocean waters. These largest of all seals were formerly hunted for their oil. Although once nearly extinct, their numbers are increasing. Fur seals, for nearly a century reported extinct, have been reported in small colonies on several subantarctic islands. Bird Island off South Georgia has a rookery estimated at 15,000 fur seals. (*See* also SEAL.)

Marine Zoology.—As a result of upwelling of replacement water, bringing up plant nutrients such as phosphates and nitrates, antarctic waters are perhaps the most productive in the world for marine animals. The enriched waters produce heavy plant plankton growths, which in turn result in rich growths of animal plankton. These are fed upon by various vertebrates and invertebrates, which results in extremely large populations of zooplankton. Representatives of most invertebrate groups are found there, one of the more important being the small shrimp *Euphausia superba*, whose food consists of plankton. This shrimp is a most important food for great numbers of vertebrates, particularly whales.

Fishes native to the antarctic are primarily of the order Nototheniiformes, a perchlike group confined to waters of the far south and somewhat analogous to the cod in the northern hemisphere. The order is remarkable for including several species that lack pigment in their blood. It is believed that the high solubility of oxygen at the temperature of the cold antarctic waters and the low metabolic rates required at these same near-freezing temperatures make it possible for these fishes to transfer sufficient oxygen to their tissues from their gills by simple physical solution in the blood plasma, without the necessity for the chemical linkage with hemoglobin that is required in nearly all other vertebrates. Other fishes include eelpouts (Zoarcidae), many species of which are circumpolar. Of the antarctic fish about 90% are of endemic species and 65% of endemic genera.

Terrestrial and Fresh-Water Animal Life.—The land and fresh-water animal life within the Antarctic convergence is comprised primarily of primitive forms of arthropods (insects, crustaceans, etc.), which are usually found among mosses, algae and lichens, or in moist soils or fresh-water pools. The more widely distributed species of insects in the antarctic appear to be parasites of birds and seals. About 44 terrestrial species are presently known and include biting and sucking lice, mites, springtails, ticks and wingless flies. Other animals include the tardigrades, or water bears, and various species of fresh-water rotifers. (C. R. E.)

5. Plant Life.—The land vegetation of Antarctica consists almost entirely of the lower cryptogams, of which the lichens and mosses are the largest plant forms. Terrestrial and fresh-water algae are equally abundant and probably more widely distributed; cryophilous (cold-tolerant) algae appear to have a restrictive range notwithstanding the fact that more than 90% of the continent is covered with ice and snow. Large showy fungi are absent from Antarctica, but the basidiomycetes, *Omphalina* and *Galerina* (Agaricales), have been reported respectively from the Antarctic peninsula, and South Georgia and other subantarctic islands. Yeasts, lower fungi and bacteria have been cultured from the primitive antarctic soils, from mosses and algae and from snow. It is quite likely that the antarctic microscopic flora is widespread, and evidence to date suggests that many species are of cosmopolitan distribution. Observations in 1965 reported the southern limits of lichens at 86° 09′ S., 176° 50′ W. at an altitude of 5,200 ft. in the Shackleton glacier area. Mosses were collected at 84° 35′ S., 174° 52′ W., at an altitude of 2,310–2,515 ft. and also at 84° 42′ S., 170° W. Bacteria were cultured from soils obtained near the Shackleton glacier.

Lichens are the most conspicuous part of the land vegetation. The fruticose *Neuropogon* occasionally grows over the ground in large dark-green patches, but it is the yellow splotches of the crustaceous *Caloplaca* on rocks about penguin rookeries that provide a modicum of colour to the coastal landscape. Lichens are much less in evidence in the interior and are generally less abundant, smaller and less conspicuous. Lichen vegetation is best developed in the Antarctic peninsula; it is relatively profuse at Wilkes and Hallett stations in comparison to that at McMurdo station or other ice-free areas south of the Antarctic circle. *Verrucaria serpuloides* in the Antarctic peninsula is unique in that it is a marine lichen, growing in the infralittoral zone to a depth of 33 ft. The actual number of lichen species is open to question, although estimates have ranged to 400 different types. In general, the antarctic lichen flora is not as well developed as that in the arctic regions.

Mosses have almost as wide a distribution as the lichens, but they are less frequent away from the coast. The moss vegetation is a striking feature in some parts of the Antarctic peninsula, where it forms dense mats to about three feet in depth and may extend in areas up to an acre. The few *Hepatica* species were believed restricted to the peninsular region, but collections of these were made at Wilkes station (1957) and Cape Hallett (1964). The Antarctic bryophytes are estimated to number about 80 species.

The Cyanophyceae, or blue-green algae, are the dominant terrestrial and fresh-water algae of Antarctica. During the austral summer small ponds quickly develop blooms of algae. The yellow, green and red snows reported from some coastal areas and subantarctic islands are an ephemeral phenomenon brought about by the sudden bloom of cryophilous algae in association with microscopic fungi and bacteria. These growths have not been reported from the interior ice cap. The larger cryptogams exhibit the same world-wide distribution of species earlier attributed to the microscopic flora.

Only two species of vascular plants, the grass, *Deschampsia antarctica*, and the pink, *Colobanthus crassifolius*, have been collected within the Antarctic circle. These plants occur only on the west coast of the Antarctic peninsula and the adjoining subantarctic islands; both are reported to produce seed. In 1953 a single specimen of the grass, *Poa annua*, was found on Deception Island; another grass, *Poa fratensis*, and the chickweed, *Stellaria media*, were later found on the Antarctic peninsula and Signy Island. There is no evidence that these weeds have established themselves. The distribution of the land vegetation, both cryophilous and ter-

restrial, is concentrated largely on the periphery of Antarctica. This serves to point up the favourable influence of maritime climatic factors and the fertilizing value of bird guano from coastal rookeries; this peripheral region also represents the greatest area of ice-free land in Antarctica. However, oases, dry valleys and other ice-free land along the coast are frequently lacking in any vegetation, primarily because of excessively dry conditions. The lower cryptogams are highly dependent on free (melt) water and this, more than low temperature, restricts their distribution. The vascular flora is thought to be limited by the consistently low temperatures, and the short growing season of the summer.

An important factor in the development of antarctic plant life is the complete isolation of Antarctica from other continents in the southern hemisphere. Botanists are divided on the natural plant provinces of the south polar regions; these have been most recently distinguished as the high antarctic, low antarctic and subantarctic. There are two theories on the origin of the present-day antarctic flora. One is that it represents a remnant of the pre-Pleistocene vegetation that managed to survive as periglacial or refugium species; others believe that the present vegetation reinvaded the continent along the Scotia Arc Islands or that plant spores and seeds were distributed south with the help of winds and birds from adjacent continents. (G. A. LL.)

III. EXPLORATION AND DISCOVERY

1. Conjecture About Antarctica.—The great bulk of knowledge about Antarctica has been accumulated since the mid-1950s because of the remoteness of the antarctic regions. However, the existence of climate zones similar to those in the northern hemisphere had been predicted by Greek philosophers; the name of the region is from the Greek *antarktikos*, "opposite the Bear," the northern constellation. The first humans to approach the far southern frozen seas may have been Polynesians. According to Rarotongan legends, Ui-te-Rangiora and his Polynesian companions made such a voyage about A.D. 650 in the canoe Te-Ivi-o-Atea. For western civilization, however, it was not until the 15th century that exploration of the southern hemisphere began, when Prince Henry the Navigator in 1418 encouraged the penetration of the torrid zone in the effort to reach India by circumnavigating Africa, which led to Vasco da Gama's rounding of the Cape of Good Hope in 1497. Successive explorations set a southern limit to the great known continents without approaching the true antarctic regions, but geographers still believed in the existence of a vast southern continent.

The search for it was a leading motive of explorers in the 16th and early 17th centuries. Men lost the fear of open oceans after the Columbian period, but they were inhibited from going far south by choice after Amerigo Vespucci, Ferdinand Magellan and Sir Francis Drake pioneered the shortest route around the tip of South America. Voyagers rounding Cape Horn frequently met with contrary winds and were driven southward, but no navigator is known to have crossed the Antarctic circle before James Cook. Almost all of those who encountered the southern ice before 1750 did so by being driven off their course and not of set purpose. An exception is the French naval officer J. B. C. Bouvet de Lozier, who during Jan. 1739 traveled through ice-encumbered sea for 48° of longitude in 55° S., a voyage that resulted in the discovery of Bouvet Island in 54° 10′ S. On Feb. 12, 1772, another Frenchman, Y. J. de Kerguelen-Trémarec, discovered land in 50° S. which he believed to be part of the southern continent. Sent out again to complete the exploration of the new land, he found it to be only the inhospitable archipelago now called Kerguelen Islands. Meanwhile, between Jan. 13–24, 1772, yet another French navigator, Marion Dufresne, had discovered the Crozet and Prince Edward islands.

2. Crossing the Antarctic Circle.—On his voyage of 1772–75 Capt. James Cook, one of the most famous British seamen of his day, boldly approached the antarctic pack ice with the sailing ships "Resolution" and "Adventure," circumnavigating Antarctica without sighting land. In the course of his voyage he crossed the Antarctic circle several times, reaching 71° 10′ S. at 106° 54′ W. on Jan. 30, 1774, a record not to be surpassed in the 18th century. He disproved connection of islands, such as New Zealand, to any southern continent, and reduced the conjectured size of Antarctica to lie within the 60th parallel. After he discovered the South Sandwich Islands in the South Atlantic he concluded that if land lay farther south it was inaccessible and valueless; and his voyage suggested that there might be no antarctic land mass at all.

Sealers.—Cook's voyage ushered in a new era of antarctic history. Mariners now dared to enter the cold seas up to the forbidding ice pack, and soon sealers began to visit southern waters, in the exploration of which they played an important part. Between 1790 and 1820 there entered antarctic waters about 19 voyages, one Australian and the rest half U.S. and half British. In 1790–92 Capt. Daniel F. Greene from New Haven, Conn., visited South Georgia and took the first fur sealskins to China. This U.S. sealing expedition was the first American approach to the antarctic and culminated in a circumnavigation of the globe. In 1810 Frederick Hasselborough, an Australian, discovered Macquarie Island.

Then suddenly the antarctic experienced an economic boom. In the period between 1819 and 1822 about 110 U.S. and British voyages were made by sealers into the area south of South America, but, because there was considerable rivalry and secrecy, discoveries became confused and lost. In Feb. 1819 William Smith of the British brig "Williams" saw land in 62° 42′ S.; repeating the voyage in October, he landed on the South Shetland Islands. Within a year these islands were the haunts of many U.S. and British sealing ships.

3. Discovery of the Mainland (1820–99).—The "Williams" with Smith aboard was chartered by the British naval commander Edward Bransfield, who on Jan. 30, 1820, surveyed the South Shetlands and went as far as 64° 30′ S. Bransfield and Smith may have been the first to discover and chart a portion of the antarctic mainland, which they named Trinity Land. Later in the same year, on Nov. 16, the young U.S. sealer Nathaniel B. Palmer discovered an archipelago and more of the mainland coast. In early 1821 Capt. John Davis, another U.S. sealer, made what appears to be the first landing on the mainland. Thus began the complex history of the discovery of the Antarctic peninsula. A party of British sealers made the first antarctic wintering on King George Island in the South Shetlands in 1821. In 1821–22 George Powell, accompanied by Palmer, discovered and surveyed the South Orkney Islands.

Bellingshausen.—In 1819 a Russian expedition was sent out under the command of Fabian von Bellingshausen in the "Vostok," with M. P. Lazarev in the "Mirny" in company, each sloop of about 500 tons. The object was to circumnavigate the antarctic area, keeping as far south as possible in those longitudes where Cook had made his northward detours. On Jan. 22, 1821, as he was completing his journey, Bellingshausen sighted the first land ever seen within the circle, the little island named for Peter I. A week later another and larger island, named for Alexander I, was seen. Bellingshausen then made for the South Shetlands and thence returned to Russia.

Exploring Whalers.—The furious slaughter of seals in the South Shetlands and South Orkneys during two seasons from 1820 through 1822 depleted the supply and came suddenly to an end. In the next 15 years an average of less than two ships per year approached the antarctic, and in some years there were none. During this period, however, as the commercial emphasis turned toward whaling, ships ranged more widely and began to push their way into the ice pack. The Enderby whaling firm of London in particular encouraged their whaling captains to explore. In 1823 James Weddell in command of the "Jane," a brig of 160 tons, with the cutter "Beaufoy" (65 tons), sailed into the sea which now bears his name and on Feb. 20 reached a new southing record of 74° 15′ S., 34° 17′ W. In 1830 John Biscoe, in command of another Enderby brig, sailed eastward from the South Sandwich Islands and crossed the circle in 1° E. He saw Enderby Land in 49° 18′ E. but was unable to reach it. Biscoe later crossed the whole of the southern Pacific in a high latitude in Feb. 1832 and discovered the Biscoe Islands and Graham Land (now Graham Coast), a south-

ward extension of Bransfield's Trinity Land and the Antarctic peninsula; the coast was named for Sir James R. G. Graham, first lord of the admiralty at that time.

In 1833 another Enderby captain, Peter Kemp, discovered Heard Island and Kemp Coast, about 10° E. of Enderby Land. Heard Island was named after the U.S. whaling captain John J. Heard, the third of the many independent discoverers of this small, out-of-the-way island in the far south Indian ocean. In 1839 John Balleny, sailing from New Zealand, crossed the circle in 178° E. and discovered the Balleny Islands.

Dumont d'Urville.—About 1835 the importance of obtaining magnetic observations in the far south, and scientific interest in the antarctic, led to plans for expeditions being put forward in the U.S., France and Great Britain. The French were first in the field; J. S. C. Dumont d'Urville with the frigates "Astrolabe" and "Zelée" was instructed to surpass Weddell's latitude in the South Atlantic. This attempt failed but on Jan. 21, 1840, he discovered the area now called Adélie Coast for Mme d'Urville. Ten days later in 64° 30′ S. he cruised westward along a high shelf of ice from longitude 131° E. and then returned northward.

Wilkes.—Charles Wilkes was appointed to command the first U.S. exploring expedition of six vessels in Aug. 1838. His instructions required him to follow Weddell's route as far as possible, to visit the most southerly point reached by Cook and to try to penetrate the southern ocean "as far west as longitude 45° E., or to Enderby Land." In following Weddell's route Wilkes in March 1839 fared no better than d'Urville in the previous year, but the "Flying Fish" (96 tons), under W. M. Walker, reached 70° S., 105° W. and reported having seen land about 100 mi. offshore from Thurston Island, discovered by Richard E. Byrd a century later. Wilkes sailed from Sydney in the "Vincennes" on Dec. 26, 1839, accompanied by the "Peacock," the "Porpoise" and the "Flying Fish." The expedition went south to the west of the Balleny Islands and cruised west toward Enderby Land. The weather was bad, and although land was reported by each vessel at several points, it was rarely seen distinctly. Some doubt was cast upon Wilkes' discoveries and his positions were occasionally inaccurate, but explorations in the 20th century revealed the coast of Wilkes Land essentially as he described it. He was first to see a major segment of Antarctica and the first to recognize the probability of a continental land mass. His locating of the south magnetic pole was also creditable.

Ross.—The British government outfitted its 1839 expedition more adequately for antarctic exploration and magnetic surveys. There were two ships, both strengthened for navigation in sea ice—the "Erebus" (370 tons), commanded by James Clark Ross, and the "Terror" (340 tons), commanded by F. R. M. Crozier. Ross had intended to make straight for the meridian of the magnetic pole but, finding that d'Urville and Wilkes had already made similar plans, determined to try to make a high latitude farther east. Leaving Hobart on Nov. 12, 1840, he crossed the circle on Jan. 1, 1841, and entered the pack ice on Jan. 5 in 174° E. Five days later both vessels reached open water of the Ross sea, which in later years proved the gateway to the continent for Scott, Shackleton, Amundsen and Byrd. A chain of mountains was sighted rising from a coast which ran due south in 71° S. This land was claimed and named for Queen Victoria. The ships continued southward in sight of land until twin volcanoes, named Erebus and Terror, were sighted in 78° S. on Jan. 28. From Cape Crozier, at the base of the mountains, a lofty ice front ran eastward, rising perpendicularly from the water to the height of 200 or 300 ft. After attaining 78° 4′ S., 167° W., Ross returned to Hobart.

In Nov. 1841 Ross returned to the same area but did not greatly extend his discoveries. However, he did break his own southing record by six miles in the neighbourhood of the Bay of Whales region along the Ross ice shelf. This record of 78° 10′ S. at 161° 27′ W., set on Feb. 22, 1842, was to stand for another 58 years, until men grew bold enough to tramp inland across the surface of Antarctica.

Return of U.S. Whalers and Sealers.—Following the briefly awakened interest in Antarctica by the French, American and British government expeditions, antarctic waters became the almost exclusive haunt of U.S. whalers and sealers from 1839 until the mid-1880s, when mineral oils began to supplant the high demand for animal oils. U.S. activities centred around Kerguelen, Crozet and Heard islands. In spite of the fact that the American Civil War brought great losses to the whaling fleets, some 200 American voyages were made to antarctic waters from the period of d'Urville, Wilkes and Ross until the end of the 19th century. During the same interval there were only about 18 British voyages, some of which were merchant vessels taking great circle routes to shorten the course around Africa to Australia and New Zealand; ships of other nations approaching the continent did not exceed a total of about 25. Aside from occupation and rediscovery of some of the off-lying islands, the U.S. sealing and whaling fleets did not add appreciably to the knowledge of the region.

During the transit of Venus in 1874, which was best observable at Kerguelen Island, American, British, German and French expeditions converged on that isolated outpost.

The first steamer to cross the circle, on Feb. 16, 1874, was the "Challenger" commanded by Capt. George S. Nares of the Royal Navy. Although the "Challenger" penetrated only to 66° 40′ S., 78° 30′ E., its dredgings and soundings showed a general shoaling of the ocean toward the antarctic ice and indicated the approach to a continent. (*See* also "CHALLENGER" EXPEDITION.)

Between 1872 and 1888 there was a revival of the sealing industry, especially at the South Shetland Islands. In 1873 Eduard Dallmann in the German sealer "Grönland" made several discoveries on the northwest coast of the Antarctic peninsula. In 1882–83 three German vessels wintered at Royal bay, South Georgia Island, making scientific observations as their contribution to the first International Polar year.

Further 19th-Century Developments.—In 1894 the Norwegian whaler Svend Foyn sent the "Antarctic," under Capt. Leonard Kristensen, to visit the coast of Victoria Land, having on board C. E. Borchgrevink, who was to return to Antarctica four years later. A small party landed on the mainland on Jan. 23, 1895.

From time to time efforts had been made by Georg von Neumayer in Germany and by Sir John Murray and others in Great Britain to inaugurate a new era of antarctic research. In 1895 Sir Clements Markham, as president of the Royal Geographical society and of the International Geographical congress, also took the matter up, and interest in the antarctic regions became general. In 1897 Adrien de Gerlache organized and led a Belgian expedition in the "Belgica," which crossed to the west of the Antarctic peninsula and made surveys of the archipelago there. The ship finally penetrated the pack as far south as 71° 30′, where it was beset for more than a year, making scientific collections of unique value. This was the first truly international antarctic expedition, with scientists and crew from many nations; Roald Amundsen, a Norwegian, was first mate and Frederick Cook, an American, was the medical officer.

The attention given to the arctic in the last half of the 19th century, especially stimulated by the search for the lost expedition of Sir John Franklin (*q.v.*), had deflected interest from the antarctic. As the century ended, however, man had lost his fear of the ice pack and was ready to begin the first serious exploration of the continent of Antarctica—a task undertaken largely by the nations of northwestern Europe.

4. Quest for the South Pole.—*Borchgrevink.*—The first expedition to winter on the continent was that of C. E. Borchgrevink, which left England in 1898 and landed at Cape Adare, the northeast point of Victoria Land. No sledge journeys to the south were possible, but valuable scientific work was done. Before returning, Borchgrevink sailed south to the Ross ice shelf and discovered that the ice front was considerably farther south than it had been in 1842. His short journey inland on skis at the Bay of Whales on Feb. 16, 1900, gave a new southing record of approximately 78° 50′ S., 165° W. It was from there that Amundsen 12 years later was to journey onward to the south pole; about 30 years later Byrd chose the site for the Little America bases.

Scott.—The British national antarctic expedition of 1901–04 was organized by a joint committee of the Royal society and the Royal Geographical society and was equipped under the superin-

tendence of Sir Clements Markham. The "Discovery," a ship of 700 tons register, was specially built for the work. The expedition sailed under the command of Comdr. R. F. Scott of the Royal Navy. McMurdo sound at the southwest corner of the Ross sea was selected as the expedition's headquarters. This area was to become not only a major centre of Scott's and Shackleton's expeditions but a half century later the major port for U.S. and New Zealand scientific activities. Before laying up for the winter, Scott cruised eastward of the farthest point reached by Ross and discovered land of continental character which he named King Edward VII Land (later known as Edward VII peninsula). Like that of Borchgrevink, this expedition initiated a new phase of exploration by working from a settled base. The main journey was that of Scott, Ernest Shackleton and E. A. Wilson, who sledged southward to a new southing record of 82° 17′ S., which they reached on Dec. 30, 1902. The second year's work was distinguished by Scott's man-hauling sledge journey to a point 300 mi. W. of the ship and more than 250 mi. inland.

Drygalski.—Simultaneously with Scott's British expedition and in full scientific co-operation with it, the German government equipped an expedition in the "Gauss," led by Erich von Drygalski. A supplementary expedition set up a station in the Kerguelen Islands. The "Gauss" crossed the parallel of 60° S., 92° E. early in Feb. 1902, but was beset soon afterward and spent the winter in the ice. Land of considerable extent was seen to the south and was named Kaiser Wilhelm II Land (later called Wilhelm II Coast); the most conspicuous feature on it was a volcanic hill called Gaussberg (Mt. Gauss), in 67° S., 90° E.

Nordenskjöld and Bruce.—Two private expeditions were in the antarctic simultaneously with the British and German national expeditions, making synchronous meteorological and magnetic observations. Otto Nordenskjöld led a Swedish party in the "Antarctic," with C. A. Larsen in command of the ship, and penetrated the Weddell sea almost to the circle in 50° W. Two winters were spent at the base on Snow Hill Island. The "Antarctic" was crushed in the ice on her way to take the shore party off, but they were rescued by the Argentine gunboat "Uruguay," under Capt. Julian Irizar.

Meanwhile W. S. Bruce equipped a Scottish expedition in the "Scotia," which made valuable oceanographical investigations in the Weddell sea in 1903 and, returning again the next summer, sighted Coats Land, named for supporters of the expedition. A meteorological station, Orcadas, established by the expedition on Laurie Island in the South Orkneys, was handed over to the Argentine government and has been occupied ever since.

Charcot.—Jean B. Charcot, a scientist and yachtsman, reached the antarctic in Jan. 1904 in the "Français," cruising along the western side of the Antarctic peninsula to 67° S., and again in 1908 in the "Pourquoi Pas?," wintering in 1909 on Petermann Island, 65° S. In the next summer he pushed farther south and west after discovering a coast later identified as Charcot Island.

Shackleton.—In 1908 Ernest Shackleton established an expedition at Cape Royd on Ross Island, his ship the "Nimrod" returning to New Zealand for the winter. A new departure in antarctic sledging was initiated by the use of Manchurian ponies. Before the winter set in, a party under T. W. E. David reached the summit of Mt. Erebus. In the succeeding summer David, accompanied by the geologist Douglas Mawson, sledged to the magnetic pole, situated in latitude 72° 25′ S., 155° 16′ E. at an altitude of more than 7,000 ft.

The greatest achievement of the expedition, however, was the journey made by Shackleton, J. B. Adams, E. Marshall and F. Wild to the latitude of 88° 23′ S., in the course of which they discovered a route on to the plateau by way of the Beardmore glacier and pioneered the way to the pole itself. As a member of this group and as a former member of Scott's southern party in 1903, Shackleton thus took part in the most extensive southward advance since Cook, and fell short of reaching the very pole itself by a mere 97 mi. Alarm over the change in appearance of the Bay of Whales deterred him from basing at this closer point, from which Amundsen met success three years later.

Scott and Amundsen.—Captain Scott again left England in 1910 with an expedition in the "Terra Nova," his objectives being a journey to the south pole and scientific investigation of the Ross sea area. The main party established itself on the west side of Ross Island. The "Fram," with a Norwegian party under Roald Amundsen, was encountered shortly afterward by the "Terra Nova" in the Bay of Whales on the Ross ice shelf. With the news of Peary and Cook's discovery of the north pole this expedition, intended for the north polar regions, had changed its plans and decided to attempt to reach the south pole instead.

After some very successful depot-laying journeys Amundsen set out on Oct. 20, 1911, for the pole, accompanied by four companions on ski with 52 dogs. They reached the polar plateau by way of the Axel Heiberg glacier in 85° S. and arrived at the pole on Dec. 14. The return journey took 38 days, and they returned to their winter quarters with 12 dogs and ample food—a model of technical performance. Another sledge party visited Edward VII peninsula to the east.

Meanwhile Scott sent a subsidiary party to Cape Adare, where they wintered in Borchgrevink's hut. This party later made a hazardous land journey of 300 mi. back to Cape Evans along the coast of Victoria Land, wintering on the way with improvised equipment. A winter journey to the emperor penguin rookery at Cape Crozier was made by E. A. Wilson, H. R. Bowers and A. Cherry-Garrard in severe conditions. The pole party started from Cape Evans on Oct. 24, 1911, with motor sledges, ponies and dogs. The motors soon broke down, the ponies were shot before reaching 83° 30′ S., and from there also the dog teams were sent back to the base.

On Dec. 10 Scott with 11 others began the ascent of the Beardmore glacier with three man-hauled sledges. On Dec. 21 four men with one sledge were sent back from 85° 7′ S., and on Dec. 31 the last supporting party of three under Lieut. E. R. G. R. Evans returned from 86° 56′ S.

The polar party—Scott, Wilson, Bowers, L. E. G. Oates and Edgar Evans—reached the pole on Jan. 17, 1912. All were tired out from their 69 days' march and bitterly disappointed to find that they had been forestalled by Amundsen. The weather on the return journey was exceptionally bad. Evans died on the Beardmore glacier on Feb. 17. Oates, at the end of his strength, sacrificed himself on March 17 in 79° 50′ S. by crawling out into the blizzard. The supply of fuel oil at the last depot had been deficient and 20 mi. remained before they reached the next. The three survivors struggled on for 10 mi. but they were bound to their camp by a blizzard that lasted for nine days, and they awaited death with quiet fortitude. The tent with the frozen bodies was found by search parties on Nov. 12, 1912.

Mawson.—The Australian antarctic expedition which set out in the "Aurora" in Dec. 1911 was organized by Douglas Mawson. The main base was established at Cape Denison at Commonwealth bay on George V Coast, where Mawson wintered with 17 companions. The ship, under the command of J. K. Davis, proceeded 1,500 mi. to the west where Queen Mary Coast was discovered, and Frank Wild landed with a party of seven men and a hut to form the western base. Sledge parties started from the main base in Nov. 1912, diverging to explore inland toward the magnetic pole and eastward and westward near the coast. Mawson's two companions, B. B. S. Ninnis and X. Mertz, perished, leaving him with scant stores 100 mi. from Commonwealth bay. He reached the hut on Feb. 10, 1913, by an effort of almost superhuman endurance and found that the "Aurora" had just sailed to relieve Wild, leaving a volunteer rescue party with whom he awaited the return of the ship in Dec. 1913.

Filchner and Shirase.—A German expedition led by Wilhelm Filchner in the "Deutschland," under Capt. R. Vahsel, penetrated the Weddell sea to 77° 50′ S. early in 1912 and delimited part of its southern boundary. The Luitpold Coast between 29° and 37° W., named for the prince regent of Bavaria, was discovered and charted. The vessel was beset in March 1912 and drifted for nearly nine months with the pack ice, finally escaping on Nov. 26 in 63° 37′ S., 36° 34′ W.

Choku Shirase led a Japanese party in the "Kainan Maru," which cruised in the Ross sea during the summers of 1910–12. A short

sledge journey was made on the Ross ice shelf, followed by a landing on Edward VII peninsula.

Shackleton.—Sir Ernest Shackleton planned the Imperial Trans-Antarctic expedition in 1914, intending to cross the continent from the Weddell sea to the Ross sea by way of the south pole. The "Endurance" entered the Weddell sea early in Dec. 1914 and worked southward between 15° and 20° W. Caird Coast was discovered between Coats Land and Luitpold Coast on Jan. 11, 1915, but no landing place was found. The ship, beset in the ice on Jan. 18, drifted northward and was crushed and abandoned on Oct. 27 in 69° 5′ S. The 28 men camped on an ice floe, which continued to move northward until April 9, 1916, when it broke up in 62° S., 54° W. after a drift of 457 days. The party took to their three small boats and landed six days later on Elephant Island. Shackleton with five men reached South Georgia, 750 mi. distant, in a 22-ft. boat and finally succeeded with the Chilean trawler "Yelcho" in rescuing the others on Aug. 30, 1916. The expedition had a companion group in the McMurdo area led by A. E. Mackintosh for the purpose of laying depots for the transcontinental party. Their ship "Aurora" was also beset in the pack ice and drifted for 315 days. The leader and two others perished.

Among a series of minor activities during the pre-World War I period was the fourth cruise of the U.S. scientific ship "Carnegie" under W. J. Peters in 1915–16, which made magnetic observations on a subantarctic circumnavigation of the continent. During 1918 and 1919 Antarctica was abandoned.

5. Exploration, 1920–40.—The first party to winter in Antarctica after World War I was the smallest expedition in Antarctic history. In 1920–22 T. W. Bagshaw and M. C. Lester, two young British explorers, landed from a whaling ship and lived for a year at Waterboat point on the west coast of the Antarctic peninsula. Despite their primitive shelter made of an upturned lifeboat and packing boxes, they carried out creditable observations of meteorology, tides and zoology.

Shackleton sailed in the "Quest" in Sept. 1921 to explore the Enderby Land area (0° to 90° E.). He died at South Georgia on Jan. 5, 1922. Frank Wild, second in command, carried on the voyage to 69° 17′ S., 17° E.

During the period from 1922 to 1928 no wintering bases were established in Antarctica and activities were confined to minor scientific investigations of off-lying islands. Whaling activities in the southern Atlantic and Pacific oceans were largely carried on by the Norwegians and in the southern Indian ocean by the French.

"Discovery" Investigations.—The Discovery committee was appointed by the British government in 1923 to undertake comprehensive oceanographical research in antarctic waters, with a view to regulating and perpetuating the whaling industry there. The first southern cruise was made by the old "Discovery" in 1925–27. In 1926 the research vessel "William Scoresby" (324 gross tons) was commissioned and during the following 12 years made eight cruises in the waters of the southern ocean. In 1929 a new research vessel, the "Discovery II" (1,036 gross tons), replaced the "Discovery" and up to the outbreak of World War II in 1939 had undertaken five southern commissions.

Christensen.—Between 1927 and 1937 a series of eight exploratory voyages in the southern ocean were promoted by the Norwegian whaling magnate Lars Christensen. During these years a large number of important geographical discoveries were made along the coasts of the antarctic mainland by expeditions led by H. Mosby, Ola Olstad, Hjalmar Riiser-Larsen, Klarius Mikkelsen and others. In the four summer seasons between 1927 and 1931 the "Norvegia" cruised in antarctic waters. Bouvet Island and Peter I Island were claimed for Norway at this time. The former island was photographed from the air during the season of 1929–30, and an air reconnaissance was made of western Enderby Land and parts of the coast of Queen Maud Land between 40° and 50° E. and 0° and 10° W. Further flights were made in 1930–31 and the coast of Queen Maud Land between 20° and 30° E. was discovered and roughly charted. In the summer of 1933–34 a number of flights were made from the "Thorshavn," during which parts of Princess Elizabeth Land were discovered. During the following season the "Thorshavn" landed a party on the Ingrid Christensen Coast, part of Princess Elizabeth Land, in about 80° E., and topographical surveys were made in that area. During one of these cruises four women guests aboard the whaler were the first of their sex to visit Antarctica. In 1936–37 part of Queen Maud Land between 30° and 40° E. was photographed from the air. Queen Maud Land was claimed for Norway in 1939.

Wilkins.—In 1928–29 Australian-born Sir George Hubert Wilkins led a U.S.-financed expedition to the Antarctic peninsula region and made an air reconnaissance of the east coast. Local flights were made again the following year. These appeared to confirm the erroneous impression, gained in 1928–29, that the Antarctic peninsula was an archipelago rather than part of the continent. Wilkins discovered the insularity of Charcot Island.

Byrd.—After his successful flight over the north pole (1926) and across the Atlantic (1927), U.S. naval aviation commander Richard E. Byrd turned his energies toward antarctic exploration, believing that airplanes and aerial cameras were the answers to exploring Antarctica. He organized a private expedition in 1928 and constructed a 42-man station, Little America, on shelf ice about four miles north of the site of Amundsen's Framheim on the east side of the Bay of Whales. On fall flights to the east he discovered the Rockefeller mountains, named for John D. Rockefeller, Jr., a patron of the expedition, and the peninsular structure of Scott's Edward VII peninsula. Farther to the east, beyond 150° W., he discovered Marie Byrd Land, named in honour of his wife, and the Edsel Ford ranges, named for another of the sponsors. During the winter night a meteorological, magnetic and auroral program was carried out. The following summer (1929) Lawrence M. Gould and a party of five sledged by dog team to the Queen Maud mountains due southward for geological reconnaissance. On Nov. 29, 1929, Byrd as navigator, accompanied by Bernt Balchen and Harold June as pilots and Ashley McKinley as aerial photographer, flew successfully to the vicinity of the geographic south pole in a tri-motored Ford airplane "Floyd Bennett." Several new glaciers were aerially mapped and the escarpment to the east of the Queen Maud mountains could be seen for another 100 to 200 mi.

Byrd returned to Little America II in Jan. 1934 after making seaplane flights from the ice-laden seas north of Marie Byrd Land. Additional buildings were erected at Little America to house the 56 members of the expedition. Cows were taken along for fresh milk. Using a Curtis Condor biplane for his major exploratory work, Byrd discovered the trend of Ruppert Coast, the Horlick mountains extending eastward of the Queen Maud mountains to at least 115° W. and peaks as far eastward as longitude 130° W. in Marie Byrd Land. (The names are for Jacob Ruppert and William Horlick, who helped support the expedition.) Byrd alone occupied Bolling Advanced Weather station about 123 mi. S. of Little America on the Ross ice shelf, the first inland station in Antarctica. During his five months' winter isolation there Byrd recorded temperatures to nearly −80° F.

The following summer four major field parties operated out of Little America. A tractor party under E. J. Demas began sounding ice thickness by seismic methods; deflected eastward on a southern journey by crevasses near 81° S., the party returned over the high plateau of western Marie Byrd Land east of the 150th meridian. This expedition made the first successful use of tractors for freighting and exploring in the antarctic. Quinn Blackburn with two companions and three dog teams retraced Amundsen's and Gould's route to the Queen Maud range and made a geological cross section up Robert Scott glacier to Mt. Weaver on the plateau 230 mi. from the south pole. Coal and fossil specimens were collected. Meanwhile, a four man dog-sledging party led by Paul A. Siple traveled eastward from Little America II to make the first mapping, geological and biological surveys of the newly discovered Marie Byrd Land. They visited the Rockefeller mountains and traveled through the central Edsel Ford ranges to the Fosdick mountains, 77° 30′ S., 144° W., named for Raymond B. Fosdick, president of the Rockefeller foundation. They collected 89 new species of mosses and lichens. The fourth important field party, led by Thomas C. Poulter, second in command of the expedition, made seismic soundings of the Ross ice shelf from the Bay of Whales to

Discovery inlet, charting ice thicknesses and ocean depths below the shelf. An extensive scientific program was carried on at Little America II, including meteorology, cosmic radiation and magnetic studies, vertebrate and invertebrate zoology, bacteriology, auroral and meteor studies, glaciology and oceanography.

Mawson.—The British-Australian-New Zealand Antarctic Research expedition led by Sir Douglas Mawson made two extensive cruises in the "Discovery" in 1929–30 and again in 1930–31. Important work was done between 45° and 75° E. and between 120° and 130° E., the coast line of these parts of Antarctica being roughly charted. A number of landings on the continent were made and Princess Elizabeth Land, Mac-Robertson Coast and the Banzare coast were discovered. The sector known as the Australian Antarctic territory was formally annexed by Australia at this time.

Ellsworth.—In 1933–34 the U.S. explorer Lincoln Ellsworth visited the Bay of Whales in the "Wyatt Earp," but his aircraft was damaged beyond use for that season. In the following summer he visited the east coast of the Antarctic peninsula with the intention of making the 2,200-mi. transantarctic flight to the Ross sea. This did not prove possible until his third trip at the end of 1935. With H. Hollick-Kenyon as pilot, Ellsworth set out on Nov. 23, 1935, from Dundee Island off Louis Philippe peninsula, for the Bay of Whales. He discovered the Sentinel mountains between 77° and 79° S. and 86° and 89° W., so named because of their prominent position as a landmark; the corridor over which he flew is now called the Ellsworth Highland. Three landings were made during the crossing of the continent and the aircraft finally arrived near the Bay of Whales on Dec. 5. These landings on unprepared terrains, made in bad weather, were a new departure in polar aviation. The two fliers were rescued by the "Discovery II" in mid-Jan. 1936. Ellsworth made one more antarctic voyage in the "Wyatt Earp" in the summer of 1938–39. A flight was made inland to 72° S., 79° E. in Princess Elizabeth Land. He named the plateau he discovered there the American Highland and claimed it for the United States.

Rymill.—The British Graham Land expedition of 1934–37, led by John Rymill, went south in the "Penola" and in successive seasons wintered at the Argentine Islands and the Debenham Islands, off the west coast of the Antarctic peninsula. In addition to comprehensive scientific investigations, flights and sledge journeys were made and the coast and off-lying islands of the western Antarctic peninsula were surveyed from the Palmer archipelago to Alexander I Island. Two major discoveries were made: first, that the Antarctic peninsula is part of the antarctic mainland and not an archipelago; second, that Alexander I Island is separated from the peninsula by George VI sound.

Ritscher.—A German expedition in the "Schwabenland," commanded by Alfred Ritscher, spent three weeks off the coast of Queen Maud Land during the summer of 1938–39. Two aircraft made extensive flights between 14° W. and 20° E., penetrating inland to about 74° 25′ S. and photographing about 135,000 sq.mi. The area was renamed New Schwabenland and claimed for Germany.

U.S. Antarctic Service.—In 1939 the U.S. government inaugurated the U.S. Antarctic service to commence permanent occupation and scientific exploration of sections of Antarctica, but the advent of World War II brought an untimely end to field operations in 1941. Admiral Byrd was assigned command, logistics were assigned to P. A. Siple and the science program to F. Alton Wade. Two major bases were established: West base, 33 men, at Little America III at the Bay of Whales, led by Siple; and East base, 29 men, at Marguerite bay, Stonington Island on the Antarctic peninsula coast, led by Richard B. Black. The U.S.S. "Bear" and the U.S.S. "North Star" serviced the bases. Using a Barkley Grow seaplane from the "Bear," Byrd discovered the Thurston Island region along the icebound coast facing the Pacific ocean near 72° S., 100° W. Byrd did not winter in Antarctica; instead he initiated the system of absentee management of the affairs of an expedition from the home country used in most subsequent expeditions. Wade was in charge of a specially built overland snow cruiser designed by T. C. Poulter for inland exploration. The 35-ton machine was underpowered and remained at Little America III as a scientific laboratory. At West base major exploratory flights included gross observation of the Ross ice shelf, aerial photography of the region between Beardmore and Robert Scott glaciers of the Queen Maud mountains, delineation of the eastern limits of the Ross ice shelf and extension of Ruppert Coast 76° S., 146° W. to Mt. Siple, 73° 15′ S., 123° W. Inland, the Hal Flood and Executive Committee ranges were more completely investigated. Aerial photography of the Edsel Ford ranges taken in February and March 1940 were reduced to maps for several dog sledge field teams working in the area the following December. The geology party of four men to the central Edsel Ford ranges was led by Lawrence A. Warner; the biological party of three to the Fosdick mountains was led by Jack E. Perkins; the Pacific coast survey party of three to the Hal Flood range was led by Leonard M. Berlin. Two additional field parties explored Edward VII peninsula, one led by Wade for geological investigations, the other for surveys by Roy G. Fitzsimmons. Extensive science programs at the main base featured the first antarctic upper air meteorological soundings, obtaining minimum temperatures of −130° F.; glaciology of the Ross ice shelf, found to move a third of a mile per year; magnetism; aurora; biology; and radio wave propagation studies. A similar scientific program was carried on at East base. Geographic discoveries included an extension of the Antarctic peninsula southward to 77° S. and reconnaissance of the peninsula northward and of Alexander I Island. A Weddell coast dog team party led by Paul Knowles did geology and surveys to 72° S., 61° W., and a second major sledge journey was made by Finn Ronne and Carl Eklund along the eastern and southern sides of Alexander I to within sight of open water along Robert English Coast. Important biological, geological and meteorological observations were made on shorter excursions near the base.

East base was evacuated by air because the ice in Marguerite bay did not break up in 1941 to permit the relief ships to enter. While awaiting relief operations, scientists of the already relieved West base made surveys and collections of botanical and geological specimens at the Melchior archipelago.

World War II Antarctic Activity.—During World War II antarctic waters became involved in military activities. Kerguelen became the "Alstertor" resupply point for German raiders Hilfskreuger 33, 16 and 45, "Pinguin," "Atlantis" and "Komet" raiding the South Pacific. The German raider "Pinguin" captured an entire Norwegian whaling fleet, including the whale factory ships "Ole Wegger" and "Pelagos," the supply ship "Solglimt" and 11 catchers. British and Australian naval vessels searched for the enemy. H.M.S. "Cornwall" sank the "Pinguin" in May 1941 after she had captured 136,550 tons of Allied shipping. After 1941 pelagic whaling ceased for the duration of the war.

In 1941 the British established a meteorological forecasting station in the Falkland Islands and destroyed fuel stocks at Deception Island. On a 1943 visit to the same island they obliterated signs of sovereignty claims left there the year before by Argentina H.M.S. "Carnavon Castle" also visited Signy bay and Laurie Island in the South Orkneys. The Argentine vessel "Primera de Mayo" made voyages to Antarctica in 1942 and 1943 to take formal possession of the sector between 25° and 68° 34′ W. south of 60° S. and to remove British emblems of sovereignty. On the latter voyage the ship visited Stonington Island in Marguerite bay and removed some instruments and materials from the U.S. East base, which were later returned to the U.S.

The winter of 1943 was the last time Antarctica was without at least a transient population.

Partly for reasons of sovereignty and partly for wartime surveillance, the British naval Operation "Tabarin I" in 1943 began permanent occupation of meteorological stations along the west Antarctic peninsula. Base A was established at Port Lockroy under the leadership of J. W. S. Marr, commander of the shore staffs, and Base B at Deception Island under the leadership of W. R. Flett. Scientific programs including geology, biology and surveys were carried on during the winter. The following year, 1944–45, the bases were relieved, and a new one, Base D, was established at Hope bay. After the war the administration of British

bases became the Falkland Island Dependencies surveys.

See also biographies of the explorers.

IV. NATIONAL EFFORTS AT OCCUPATION (1943–55)

1. Conflicting Claims.—During the decade following World War II. attitudes toward Antarctica became singularly nationalistic. Claims of territory had been announced by seven countries—the United Kingdom, Australia, New Zealand, Norway, France, Argentina and Chile. The only remaining segments of the continent not specifically claimed lay between 90° and 150° W. in west Antarctica and between 45° E. and 20° W. in east Antarctica, southward toward the pole from the explored coast claimed by Norway. The basis of claims varied with individual countries, although, with the exception of Norway, the claimants adhered to the "sector" principle, propounded by Pascal Poirier in the Canadian senate on Feb. 20, 1907. His concept would recognize the extended claims of any nation bordering the polar regions by extending the meridians of its extreme boundaries to the north or south pole. The concept has never been tested in a world court, and the United States has been notably among those nations which have never accepted the principle in either the arctic or antarctic. The majority of claimants in Antarctica have used this sort of convenient pie-shaped wedge claim system, but their reasons for the chosen boundaries have been devious and varied. The French claim of Terre Adélie, for example, extends d'Urville's coastal discovery of 1840 to the pole, although he did not set foot on the land and the first French return to the area was not until Dec. 1949; but the more intensive and extensive explorations of Charcot in 1903–05 were not used as a basis of claim. Norway made no attempt to exploit the discoveries of Amundsen but claimed the Russian-discovered (1821) Peter I Island and the French-discovered (1739) Bouvet Island; the coast claimed by Norway was largely explored by Norwegian whalers, although it lies in the sector which South Africa might conceivably claim if it extended its boundaries according to Poririer's principle, as Argentina, Chile and Australia have done.

The vigorous British claim to the Falkland Island dependencies is based upon some priority rights of discovery, but the region includes land and islands first explored and, in some cases, occupied by the U.S., the U.S.S.R., France, Sweden, Germany, Norway, Belgium, Argentina and Chile. Although other nations might assert justifiable formal claims in this region, only Argentina and Chile, who previously had explored it less than some of the others, have formally made such assertion. Argentina, in addition, voices claim to the Falkland Islands and South Georgia. Argentina's nearly 60 years' occupation of the Laurie Island weather station gives it the longest record of possession of any single spot in Antarctica south of 60° S.

U.S. policy as stated by Charles E. Hughes, secretary of state in 1924, that occupation was the strongest basis for claims of a territory, had an impact on antarctic exploration. The U.S. Antarctic service, 1939–41, was intended as the first step toward occupying Antarctica on a permanent basis, but the effort had to be temporarily abandoned because of World War II. Even before the war had ended British naval forces established three bases in the Falkland Island dependencies and announced them as permanent meteorological stations. These stations opened post offices, issued postage stamps and had appointed barristers. Britain added progressively to the number of permanent stations during the next decade, as did Argentina and Chile, sometimes at the same sites and manned by military personnel. High officials, governors of provinces, and even the president of Chile and Prince Philip of Great Britain visited their countries' respective stations. The competition for possession grew serious enough that whenever foreign stores, national emblems or unoccupied refuge huts were discovered, they were destroyed. Arrests and deportations occurred and there was one instance of armed resistance without casualties by Argentina against a British landing party at Hope bay in 1952. British naval war vessels put in an annual appearance in the Falkland Island dependencies and during 1948 Argentina had about 15 naval vessels in the area on maneuvers, in addition to a 13-vessel flotilla to establish bases. Tension caused by this show of naval force was eased somewhat after 1949 by annual declarations between Argentina, Chile and Britain aimed at restricting the use of warships.

By the outset of IGY in the 1956–57 season the British were occupying 11 permanent stations, Argentina 8 and Chile 6. Although these stations were primarily political, valuable work resulted during the nationalistic decade. The Chileans did some hydrographic and survey work. The Argentines did comparatively more scientific work and produced superior hydrographic charts of the regions surrounding the South Shetlands, South Orkneys and the Antarctic peninsula. The British were still better equipped for biological, geological and electromagnetic reconnaissance and in addition did superior ground surveys and mapping of the land. Vertical aerial-strip surveys of the entire northern half of the Antarctic peninsula were accomplished, resulting in the most detailed maps of any portion of Antarctica.

At the close of the nationalistic period, the continent's periphery was mapped for the first time and U.S. personnel, with the aid of aircraft, had seen more of Antarctica than all other explorers combined. However, the U.S. continued its policy of making no official territorial claims, recognizing no one else's claims but reserving its rights to make claims at a future time. In 1950 the U.S.S.R. announced a similar policy, and although it had done no active exploration since 1822, it had been carrying on whaling since 1946 and was preparing to take a highly active part in IGY antarctic activity. Germany and Japan were forced to surrender their rights to antarctic claims at the close of World War II.

The accompanying station location table will help to clarify the sequence of activities from 1943 to 1955, which were especially complicated in the British, Argentine and Chilean area around the South Shetland and South Orkney islands and the Antarctic peninsula. The station list includes, for the most part, only bases that were occupied through one or more winter seasons. It does not include temporary summer stations or many refuge huts built by these nations.

Beginning during the IGY in 1957–58 an attitude of international co-operation began and in most cases national claims were not pressed. After the signing of the Antarctic treaty in 1959 virtually all territorial claims were placed in abeyance.

2. Operation "Highjump" and Other U.S. Expeditions.—In 1946–47 the U.S. naval task force 68 undertook Operation "Highjump," the largest expedition attempted in the antarctic up to that time. The enterprise was under the general direction of Rear Admiral Byrd and the 13 ships taking part were commanded by Rear Admiral Richard H. Cruzen. The objectives were to test equipment, to give polar experience to 4,000 men, to extend the basis for United States claims and to photograph as much of Antarctica as possible from the air. The task force was divided into three groups and worked around most of the periphery of the continent during the summer. More than 100 men were based at Little America IV from January to March. Operation "Highjump" utilized six R4D aircraft, the largest planes to take off successfully from a carrier and subsequently from the improvised snow surface airstrip. In the first of these, Admiral Byrd flew to the base from the aircraft carrier "Philippine Sea" near Scott Island. Twenty-nine photographic flights extending into previously unexplored territory radiated into Marie Byrd Land, the Horlick mountains, the polar plateau and Victoria Land. Byrd made his second flight over the geographic south pole on Feb. 15, 1947. Some meteorology, glaciology and geophysical work was accomplished. P. A. Siple led an attached war department, army and air force observation team. The eastern group under command of Capt. George J. Dufek explored and photographed by seaplane the Pacific coast area of west Antarctica between Mt. Siple and Charcot and Alexander I islands. One aircraft crashed on Thurston Island with loss of part of its crew. This group later circumnavigated the Antarctic peninsula and Weddell sea to explore part of Princess Martha Coast. The Western group under Capt. Charles A. Bond explored and photographed by seaplane the coasts of east Antarctica from Oates Coast to the Princess Astrid Coast. Near longitude 100° E. this group discovered Bunger Hills, an extensive area of ice-free land, misleadingly called an oasis.

A smaller naval expedition, designated Operation "Windmill," consisting of two icebreakers under Comdr. G. L. Ketchum, visited Antarctica during the following season. The object was to fix geographical points so that the air surveys of the previous expedition could be properly located.

A private antarctic research expedition, heavily supported by government sources, was undertaken by Finn Ronne in 1946–48. The expedition reoccupied East base of the U.S. Antarctic service (1939–41) at Stonington Island in southwest Antarctic peninsula. Noteworthy scientific and topographical survey work was accomplished, some of which was in co-operation with the staff of the Falkland Island Dependencies survey's southernmost station, also at Stonington Island. An important summer journey of 1,180 mi. was made, using British sledging equipment and U.S. air support.

Stations in Antarctica Established by Various Countries

*"P" after station names indicates permanency; "I" after station names indicates that it carried on IGY, S.C.A.R. and IQSY programs. †Names in parentheses denote responsible senior leader not in residence at the station. ‡Years occupied prior to 1961. §Leader first year of IGY. ||Intermediate station.

The combined party reached 74° 45′ on the east coast of the Antarctic peninsula and returned after 105 days in the field. Mrs. Ronne and Mrs. Harry Darlington, who accompanied their husbands, were the first women to winter on the antarctic mainland.

3. A.N.A.R.E.—The Australian National Antarctic Research expedition (A.N.A.R.E.) was established by the Australian government in 1947 under the direction of Stuart Campbell and later of P. G. Law. Scientific stations were set up on Heard Island in Dec. 1947 and on Macquarie Island in March 1948. The Heard Island station was closed in 1955; the Macquarie Island station was operated continuously, annual relief parties being sent to the island each summer. In Feb. 1954 Mawson station, led the first year by R. G. Dovers, was established on the antarctic mainland and has been maintained permanently. Subsequent explorations along the coast and inland have added much to the knowledge of this region. The Prince Charles mountains were found to extend inland to about 74° 30′ S.

4. Other Events.—In Dec. 1947 the South African government annexed the Prince Edward Islands, which lie halfway between South Africa and Antarctica, and in Feb. 1948 a weather station was erected on Marion Island. This station has been manned by successive relief parties since that time.

An antarctic expedition organized by the private body known as Expéditions Polaires Françaises, under the direction of Paul-Émile Victor, established a station at Port Martin in Jan. 1950. A. F. Liotard was in command during the first year. He was succeeded by M. Barré early in 1951. During 1950 and 1951 a number of important journeys were made in mechanical tracked vehicles along the Adélie coast line and inland toward the magnetic pole. The station at Port Martin was destroyed by fire in Jan. 1952, but a small party led by M. Marret wintered at Pointe Géologie, about 40 mi. E. of Port Martin.

In Dec. 1949 the French government established a large scientific station at Port-aux-Français on the Kerguelen Islands. The station was manned continuously after Jan. 1951 by members of an official organization known as Missions aux Terres Australes et Antarctiques Françaises, under the direction of Pierre Sicaud. An airfield was established on the islands, which lie midway between South Africa and Australia.

An international expedition, sponsored by the Norwegian, British and Swedish governments—the first of its kind—worked in Queen Maud Land in 1949–52. The primary objective was to try to determine whether the antarctic icecap is waning, as is true of most northern glaciers, in response to a warming climate trend which has been in progress since 1900. The expedition, which was led by the Norwegian John Giaever and comprised members of all three nationalities, established a station called Maudheim on a floating ice shelf. During the field seasons of 1950–51 and 1951–52 a number of journeys were made, using mechanical tracked vehicles and dog sledges, and an advanced base was established in 72°. 17′ S., 3° 48′ W. An important seismic sounding journey was made inland to a point 370 mi. from Maudheim on the inland ice plateau. A number of flights were made over Queen Maud Land and air photographs were taken.

V. INTERNATIONAL CO-OPERATION

1. International Geophysical Year.—When the committee in charge began organizing the International Geophysical year, to extend from July 1, 1957, to Dec. 31, 1958, it became apparent that nearly a fifth of the world-wide data to be collected would be missing if Antarctica was not included in the effort. Of the 66 nations that eventually joined the IGY effort, 12 volunteered to use existing stations in the antarctic regions or to establish new ones. The south pole was to become the tie point of north-south lines of stations extending through the other continents. It became further obvious that inland stations would be required as well as ones on the coast. These would be both costly to build and difficult to achieve. Only the United States and the U.S.S.R. volunteered to use their resources to attain far inland goals, although France and the United Kingdom later placed small stations short distances inland.

The seven claimant nations all played an active role but restricted their station efforts to localities within their claimed areas. The nonclaimant nations taking part, in addition to the U.S. and U.S.S.R., were Japan, Belgium and South Africa. Correlation was achieved by means of an International Antarctic committee organized in Paris in 1955. The nonclaimant nations established their stations in gap areas to improve spacing. In some cases, however, there were more stations than were essential to the program; for example, the United Kingdom, Chile and Argentina had stations at Deception Island and Hope bay and the U.S., the United Kingdom and Argentina established new stations not far apart on the Filchner ice shelf. On the other hand, areas such as the Pacific-facing coast of west Antarctica were neglected because of the difficulty in approaching them; its protecting pack ice was first breached in 1960, well after IGY.

Along the coast of Norwegian-claimed Queen Maud Land, nearly 2,000 mi. long, Norway's single station on the Princess Martha Coast was joined by a Japanese station, Showa at Prince Harald Coast on Lützow-Holm bay, and by a Belgian station, King Baudouin station on Princess Ragnhild Coast. Australia added Davis station at Princess Elizabeth Land on Ingrid Christensen Coast to its existing Mawson station. To help fill in gaps along this coast the U.S. located Wilkes station on Budd Coast and the U.S.S.R. located two stations, Mirny on Queen Mary Coast and Oazis at Bunger Hills in Wilkes Land. The French station Dumont d'Urville at Point Géologie on the Adélie Coast further filled in the observing points in this region. The French also established a small, temporary inland station, Charcot, near the south magnetic pole. In its claimed Ross dependency sector New Zealand established Scott station on Ross Island, McMurdo sound, close to the Williams naval air facility, a U.S. installation. The U.S. and New Zealand jointly established Hallett station at Cape Hallett near Cape Adare of Victoria Land. The U.S. main IGY station, Little America V, was established in this same sector at Kainan bay, about 20 mi. N.E. of the former Little America sites.

In the Weddell sea sector claimed in part by both Britain and Argentina the latter built General Belgrano station just prior to IGY. Later, and nearby on the Filchner ice shelf, the U.S. built its Ellsworth station and Vivian E. Fuchs his Shackleton station for the British Trans-Antarctic expedition, only coincidentally a part of IGY. This group also built a support station, South Ice, inland. The only strictly new British IGY station, Halley Bay, was established about 250 mi. to the northwest on Coats Land. In the area of the Antarctic peninsula and the South Shetland and South Orkney islands claimed by the United Kingdom, Argentina and Chile, 24 of the nationalistically motivated stations took creditable part in the IGY program. Seven of these were Argentine, six were Chilean and the remainder British.

The United States built two major inland stations in support of the IGY effort. Byrd station at 80° S., 120° W. was established by tractor and air support; the geographic south pole station Amundsen-Scott was established entirely by air. The U.S.S.R. originally planned two inland stations, Vostok, to be established at the south geomagnetic pole (where the earth's magnetic field focuses downward from outer space), and Sovietskaya, to be in the geographic centre of the continent. Because of high elevations and soft snow the mobile stations failed to reach the sites on schedule, and in consequence the intermediate stations Pionerskaya, Komsomolskaya and Vostok I were established as overwintering sites en route and Sovietskaya was established about 400 mi. short of its goal.

In the wide expanse of antarctic waters and far southern oceans there are few islands suitable for stations. A number, however, served as useful IGY station bridges to the surrounding continents: Kerguelen (France); Campbell (New Zealand); Macquarie (Australia); Marion, Tristan and Gough islands (South Africa); and Falkland and South Georgia islands (United Kingdom).

Logistic support for the stations followed various patterns. Danish iceworking ships built for Greenland commercial travel were chartered by several nations. The U.S.S.R. used its icebreaking oceanographic vessels "Ob" and "Lena" as well as other vessels out of their Northern Sea Route administration. The U.S. logistics support was assigned to the department of defense

20TH-CENTURY EXPEDITIONS AND SCIENTIFIC RESEARCH

(Above) Launching a helium-inflated balloon into the upper atmosphere; (top right) Installing a 40-ft. steel arch across the garage tunnel at Byrd Station; (right) Sno-cat tractor transporting supplies across a crevasse in the icecap during British Trans-Antarctic expedition, 1957

and on to the U.S. navy, which in turn called upon the air force and the army for specialized assistance. Rear Adm. George Dufek of the United States navy was assigned command of the logistics task forces, called Operation "Deepfreeze." Naval personnel were assigned with their own command lines to furnish medical, communication, construction and station maintenance, whereas the scientific program was under a separate civilian command line responsible to the National Academy of Sciences. Until his death on March 11, 1957, Admiral Byrd was responsible for the over-all administration of the U.S. Antarctic programs.

The scientific programs of the IGY concentrated upon synoptic subjects which required simultaneous readings from the many scattered stations. The principal subjects included surface and upper atmosphere meteorology, geomagnetism, ionospheric physics, aurora, seismology, cosmic radiation, oceanography and glaciology. The latter study was intended to determine the history of past climate variations and trends as revealed by snow accumulation rates. Although mapping and geology were not part of the program, they were encouraged, as were biological studies. Glaciology traverses by cross-country tractor and aircraft included seismic ice depth determinations and earth gravity determinations. Although traverses were run out of many of the stations, those by the U.S. in west Antarctica and by the U.S.S.R. in east Antarctica were the most extensive. More spectacular was the transantarctic crossing by a British tractor party led by Vivian E. Fuchs—the first overland crossing of the continent. The trip began from Shackleton station on the Weddell seacoast and ended at Scott station on the Ross seacoast. Support for the journey past its midpoint visit at the U.S. south pole station was given by a tractor party led by Sir Edmund Hillary from the New Zealand Scott station. The traverses of all stations revealed that the land mass beneath Antarctica's ice cover is extremely rugged. The cap averages a mile in thickness and in many places goes far below sea level, indicating in general that west Antarctica is mostly an island grouping and that east Antarctica is more truly continental.

Coastal stations were similarly equipped but varied in size depending upon the scope of problems they were handling. Little America, McMurdo and Mirny had more than 100 inhabitants during the winter and many more during the summer season. Little America V served as the main U.S. scientific administration and communications centre under A. P. Crary. This station also served as the Weather Central for the continent. There was some exchange of foreign observers among the bases, including a U.S.S.R. observer at Little America V and a U.S. observer at Mirny, a practice continued after the end of IGY.

Of the inland stations Byrd station was the largest, serving as support for traverse operations. It was established by an army-pioneered tractor train party from Little America V. The Russian and French inland stations were modified mobile units dragged inland. The most unusual of the stations was the U.S. Amundsen-Scott south pole station, established by air force parachute drops and navy ski airplane landings. The station of 18 men, led by IGY leader P. A. Siple and naval leader J. Tuck, was the first base at either of the earth's poles to be inhabited for a year. During the six sunless winter months a world record low temperature of $-102.1°$ F. was recorded. Average winter wind speeds were about 17 m.p.h. and the average temperature $-73°$ F. at this 9,200 ft. elevation. A year later, Aug. 25, 1958, at the 11,220-ft. Russian Vostok station, where winds were less, a minimum temperature of $-125.3°$ F. was recorded. (Subsequently, on Aug. 24, 1960, a temperature of $-126.9°$ F. was reported there.)

The IGY program amassed great volumes of information which may require years to fully analyze and co-ordinate. The IGY nations formed three major data centres in which the raw data and final reports were sent for processing and exchange with the other centres. Data Centre A is assigned to the United States, serving generally North and South American countries; Data Centre B is assigned to the U.S.S.R., serving Asia and especially the communistic nations; and Data Centre C is in western Europe, serving also Africa and Australasia. Each data centre is in turn divided into subcentres by various subjects and scientific disciplines. In the U.S. these centres are variously located in universities, research institutes or government departments, such as the weather bureau and the national bureau of standards, dealing nationally with meteorology and ionospheric physics.

By the 1960s masses of publications were already appearing in all three centres and being widely exchanged according to agreement. The antarctic data are incorporated with data from all

parts of the world except in cases unique to the region.

The IGY was the largest international scientific undertaking of all time, and the intense study of Antarctica was one of its greatest achievements. IGY may stand as a prototype of international undertakings in the pursuit of knowledge for the common good of the world; but whatever its full assessed value may be, its initial stimulus to the large-scale study of Antarctica cannot be overestimated.

2. Special Committee for Antarctic Research.—Stimulated by the success of the IGY and the recognition that the high investments in stations justified their further utilization, the international effort in Antarctica was extended beyond the closing date of IGY, Dec. 31, 1958. A Special Committee for Antarctic Research (S.C.A.R.), under the International Council of Scientific Unions, replaced the IGY Antarctic committee for international scientific co-operation of the 12 nations which had carried on the antarctic IGY activity. The organizing meeting was held at The Hague in Feb. 1958; the second meeting was in Moscow in Aug. 1958 and the third in Melbourne in 1959; meetings took place almost annually thereafter. Although most of the stations were still active during 1959 and 1960 some began to change sponsors. The U.S. Ellsworth station on the Weddell coast was transferred on co-operative loan to Argentina with continued U.S. support to the science program; the Wilkes station was transferred to Australia; the U.S.S.R. Oazis station was offered to Poland, which, however, found difficulty in gaining support; and the single Norwegian station was transferred to South Africa. The U.S.S.R. opened a new station, Lazerev, on Astrid Coast of east Antarctica facing Africa. By the mid-1960s it had become the U.S.S.R.'s main station, and Mirny began to be reduced in size and importance.

Traverse activity, frequently of international composition, was continued at an increasing pace, and mapping and geology neglected during IGY was encouraged. U.S. traverses extended widely over west Antarctica, reaching Pacific coastal mountains in the north and the Horlick mountains in the south. In 1960 the powerful icebreaker U.S.S. "Glacier" broke through the previously impenetrable pack ice of the southern Pacific area and reached the Thurston Island region of Marie Byrd Land, opening a way for stations along this coast, and en route repositioned mountain peaks in the Executive Committee range. Vinson Massif (16,863 ft.), at 78° 35′ S., 85° 25′ W., appeared to be Antarctica's highest known peak. A United States–New Zealand traverse party crossed Victoria Land into Terre Adélie.

A U.S.S.R. traverse visited the U.S. south pole station in Jan. 1960, traveling en route from Mirny via Vostok. Resupply of Byrd and the U.S. south pole stations was accomplished in part by C-130 cargo aircraft landing for the first time on ski.

3. Antarctic Treaty.—Stimulated by the success of international co-operation in Antarctica during the IGY, the 12 nations that had taken part in the endeavour signed a treaty in Washington, D.C., on Dec. 1, 1959; later other nations acceded to it. Formal ratification of the treaty was announced two years later when the contracting nations convened in Canberra, Austr., to further the purposes and objectives of the treaty. The treaty dedicated Antarctica for peaceful purposes only and restricted its use for military purposes. It promoted international co-operation in scientific research, exchange of personnel, information and results.

No member nation was required to renounce its claims or previously asserted rights to claims. However, there was to be freedom of operation anywhere about the continent, although no such operations were to form a basis for new or extended claims during the time the treaty was in force.

Nuclear explosions and disposal of radioactive wastes in Antarctica were prohibited, although peaceful and scientific use of atomic devices was permitted. The treaty applied to the regions lying south of latitude 60° S. but did not restrict normal freedom of the high seas included in this area. There were elaborate provisions for exchange of plans, observation, inspection and settlement of possible disputes. The treaty had provision for new member nations wishing to take an active part in antarctic activities and bound its members for a period of 30 years.

As a result of the treaty a majority of the nations continued most of their IGY programs unabated. Considerable attention was given to surveying, mapping and geological reconnaissance until the advent of the International Years of the Quiet Sun.

4. International Years of the Quiet Sun (IQSY) 1964–65.—Because of the work begun and facilities established during the IGY, which was held during a period of high sunspot activity, antarctic research stations required little more bolstering of scientific programs to be prepared for the IQSY when solar sunspot activity fell to a minimum in its normal cycles. Studies of meteorology, upper atmosphere, ionospheric sounding, cosmic radiation, aurora, and radio wave propagation were emphasized. Although the intensiveness of some antarctic research will decrease and increase with new programs of this nature, the international co-operation enthusiastically pursued under the treaty is expected to keep permanent activities going on indefinitely. Most stations maintained strong summer programs with an influx of temporary staff, while the winter personnel were fairly well stabilized in numbers. These latter groups were replaced annually, though many of the workers returned for another tour of duty. Thus individuals are carrying on what may become a lifetime career in antarctic scientific activities and becoming in a sense Antarctica's first inhabitants.

5. Future Prospects for Antarctica.—Despite the facts that Antarctica had its first temporary year-round inhabitants at the turn of the 20th century, that it is still incompletely explored and that its periphery outlines were mapped only after World War II, it is being so intensively studied that it will soon be as well known as most of the rest of the world's continents. Technological advances after 1940 provided a means of safe access, and the fearful shrouds of the unknown and the intense cold lost their inhibiting power. This once bleak, lifeless continent teems with hundreds of men each year, wresting out the challenging problems and answers to its hidden secrets. Man will not rest until he knows the relationships of Antarctica's physical character, history, life and phenomena to those of the rest of the world. The Antarctic treaty has proven to be a further stimulus and it is reasonable to expect that well before the close of the 20th century the continent will be fully explored and well mapped both as to surface and subglacial features; the geology of most exposed mountain areas will have been studied and the mineral resources assayed; weather forecasting will become a permanent part of a world meteorological forecasting system; electromagnetic phenomena of the region will be correlated with global phenomena as well as solar and extraterrestrial space events; the flora and fauna will have been intensively studied and their distribution well mapped; the surrounding oceans will have been systematically studied as to physical character and biological distributions; in short, the continent will be as well, if not better, understood as regions of the world enclosed by firm national boundaries, for the exchange of new knowledge will be expedited through international channels. It is also reasonable to expect that technology of travel and living will soon permit during any month of the year access to any part of the continent from any of the surrounding continents; nuclear reactors are already furnishing heat, power and water to comfortable houses and facilities of sizable communities; space satellites are already supplementing surface studies and atmospheric sounding rockets have been launched in Antarctica; commercial air travel in the southern hemisphere will likely be using great circle routes across Antarctica; colonization of a unique sort will be initiated by families under contract manning permanent meteorological, communication and scientific data recording centres and outposts; and some food may even be produced locally.

On a somewhat longer time scale, but probably within the 20th century, industrial centres may develop for those industries requiring extensive space, safety of operation, freedom of contamination, large quantities of fresh water reserves or natural refrigeration. Extensive mining operations will depend upon discovery of minerals which can compete with lower cost sources in other parts of the world; however, some development of commercially extracted by-products of antarctic coal reserves appears possible.

The most significant aspect of Antarctica's future, however, may lie in its becoming the first free region of the world, a step to

internationalizing the world of the future. National claims of the present are so confused and basically indefensible by protective forces that they will likely weaken until they give way to a continent whose inhabitants and visitors are free from normal national restrictions of movement or commerce, and are subject only to a form of yet-to-be-defined international laws. This international experimentation and co-operation may be of greater value to mankind than Antarctica's future material potential.

ANTEATER, a term applied to several mammals that feed mainly upon ants or termites. The giant anteater or antbear (*Myrmecophaga tridactyla*) is the largest representative of the tropical American family Myrmecophagidae (*see* Edentata: *Hairy Edentates: Sloths and Anteaters*). It measures four feet in length, exclusive of the long bushy tail, the hair of which may be 16 in. long, and reaches a height of two feet at the shoulder. Its usual colour is gray-black. It inhabits the swampy savannas and humid forests of South and Central America, but is nowhere common. Characteristic features are the long tapering snout, small mouth, absence of teeth and the strong curved claws on the forefeet. With the latter it not only defends itself effectively but also tears holes in the dwellings of ants and termites, capturing the inhabitants by means of its long sticky tongue, which it extends for about nine inches and lashes from side to side. The female produces a single young at a birth. The young ride on the backs of the mothers the first few months after they are born. The tamandua anteater (*Tamandua tetradactyla*) is smaller and arboreal, inhabiting the forests of South and Central America. Also arboreal is the little or two-toed anteater (*Cyclopes didactylus*) of the same region, about the size of a rat and yellowish in colour.

For the Cape anteater, *see* Aardvark; for the scaly anteater, *see* Pangolin; for the banded anteater, *see* Marsupial; and for the spiny anteater, *see* Monotreme and Echidna.

ANTELAMI, BENEDETTO (active after 1178), the preeminent Italian architect and sculptor of his time, is named for the first time in an inscription on a relief of the "Deposition" dated 1178 in the right transept of Parma cathedral. Of Lombard origin, he appears to have worked initially in Provence, and the influence of the Romanesque sculptures of St. Gilles is reflected both in the "Deposition" and in his masterpiece, the sculptures of the baptistery at Parma. Antelami's principal achievement as an architect, the baptistery, was begun in 1196 and appears to have been largely completed by 1216.

In the later sculptures of the baptistery and the figures of David and Ezekiel on the façade of the cathedral of Borgo San Donnino (Fidenza), there is evidence of contacts with the early Gothic sculptures of the Ile-de-France. These contacts assume preponderant importance in Antelami's last work, the church of S. Andrea at Vercelli (founded 1219, consecrated 1225), where the architectural scheme derives from that of St. Ived de Braisne and the lunette of the "Martyrdom of St. Andrew" over the portal also contains recollections of French Gothic sculpture. Despite his indebtedness to France, Antelami developed a style of great individuality and occupies an unchallenged place as the greatest Italian Romanesque sculptor.

See G. de Francovich, *Benedetto Antelami, architetto e scultore* (1952). (J. W. P.-H.)

ANTELOPE, the name of numerous ruminant ungulates of the superfamily Bovoidea. Antelopes range in size from that of a rabbit to that of a large ox and nearly all bear horns, at least in the males.

The antelopes, sheep, goats and oxen are all fairly closely related to each other and, together with the pronghorn, form the very large superfamily Bovoidea, which is divided into two families, the Antilocapridae, made up of a single species, the American pronghorn; and the Bovidae (*q.v.*), consisting of more than 50 living genera. The name antelope, however, cannot be defined exactly in zoological terms because it is applied to animals that, although superficially similar, do not form a homogeneous group. Popularly, the animals classified as the Bovoidea consist of three groups, the antelopes, containing all the animals that cannot be included in the other two, the oxen and the sheep and goats, a classification that is not in agreement with the zoological classification based on their relationships to each other.

THE ANTILOCAPRIDAE

The pronghorn *Antilocapra*, the only living representative of the Antilocapridae, is confined to North America, but the name "American antelope" commonly applied to it in the United States is regarded as a misnomer in view of its distant zoological relationship to the true antelopes (*see* PRONGHORN).

JOE VAN WORMER FROM NATIONAL AUDUBON SOCIETY

FIG. 1.—MALE PRONGHORN ANTELOPE (ANTILOCAPRA AMERICANA)

THE BOVIDAE

Subfamily Bovinae.—The first groups of antelopes among the Bovidae are the tribes Strepsicerotini and Boselaphini of the subfamily Bovinae, both closely related to the Bovini (oxen, buffaloes and bison).

Strepsicerotini.—The Strepsicerotini contain the bushbucks and their allies and include some of the largest antelopes, such as the kudu and eland. They are large- or medium-sized antelopes with spirally twisted horns present only in the males. The bushbucks, including the harnessed antelope (*Tragelaphus scriptus*), are frequently brilliantly coloured, the body being rich chestnut or orange-brown with a white nasal chevron and longitudinal and transverse stripes on the body. They are widely distributed over forested Africa south of the Sahara and extend to the Cape. The nyala (*T. angasi*) is a much larger species, the male with larger horns and a mantle of long hair on the sides. The male is blackish in colour, the female a dark chestnut, and both are marked with stripes like those of the bushbuck. Nyala are restricted to a small area in southeastern Africa. The mountain nyala (*T. buxtoni*) is the largest member of the genus, standing nearly as high as the kudu. It is grayish-brown in colour. This fine species lives on the high mountains near Lake Zwai in Ethiopia. The sitatunga (*T. spekei*) is a little larger than the bushbuck, with longer limbs and elongated hoofs, an adaptation to the mud and soft marsh ground. Sitatungas are found from west Africa to the Sudan and south-central Africa. The greater kudu (*T. strepsiceros*) stands nearly five feet at the shoulder; males possess large spirally twisted horns. This species is distributed throughout much of the plains country of Africa south of the Sahara. The lesser kudu (*T. imberbis*) is only about 40 in. tall at the shoulder and has much smaller horns. It is restricted to the drier parts of east Africa, from southern Ethiopia to Tanganyika. The eland (*Taurotragus*) is the largest of the antelopes, adult bulls standing nearly five feet at the shoulder. The common eland (*T. oryx*) of south and east Africa, differs from the Derby eland (*T. derbianus*) by having smaller, less massive horns and narrower ears. The larger form is found south of the Sahara from Senegal to the Sudan and the northern section of the Republic of the Congo. The bongo (*Boocercus eurycerus*) is a close relative of the eland, found in west Africa, the Congo and certain mountain forests. It is bright chestnut in colour with 10 to 13 white vertical stripes on the body. Both male and female bongos bear horns, much more loosely spiraled than those of the eland.

Boselaphini.—The Boselaphini contain only the nilgai, or blue bull (*Boselaphus tragocamelus*), and the four-horned antelope (*Tetracerus quadricornis*), both found in peninsular India. The adult bulls of the nilgai are bluish-gray, with short, slightly spiraling horns, but the females are pale yellow and hornless. The four-horned antelope is a small forest-living species and differs from other antelopes in that the males, at least in one race, have two pairs of horns, the first pair being smaller.

Subfamily Cephalophinae.—This subfamily comprises one tribe, the Cephalophini, containing the duikers or duikerboks, is the most primitive subfamily of the Bovidae. Duikers are small or medium in size and are characterized by their spikelike horns which are commonly present in both sexes, their naked muzzles and large face glands represented externally by a long narrow streak below the eye. The female has four teats. *Cephalophus*, including the forest duikers, is distinguished by horns sloping back almost in line with the profile. Most species are confined to the equatorial rain forests or follow the gallery forests along rivers. The largest members of the tribe, the yellow-backed duiker (*C. sylvicultor*) and Jentink's duiker (*C. jentinki*), stand 30 in. or more at the shoulder, but other species are smaller (height 16–24 in.). The blue duikers are the smallest members of the tribe; their horns are very small, usually present in both sexes. Their colour varies from bluish-gray to grayish-brown. They live in the forests but extend also into the bush country of South Africa. *Sylvicapra grimmia*, the gray or common duiker, is the sole representative of its genus. The males have slender horns, longer than those of other duikers. This duiker is widely distributed in south, central and east Africa.

Subfamily Hippotraginae.—The Hippotraginae are large- or medium-sized antelopes with ringed horns and high-crowned cheek teeth but without facial glands. There are three tribes, the Reduncini, Hippotragini and Alcelaphini.

Reduncini.—The Reduncini include five genera with sinuous or forward-curving horns, found only in the male. The muzzle is naked. *Kobus* includes the two species of waterbuck. *K. ellipsiprymnus*, the common form, is found in east and central Africa from Somalia to the Transvaal, and the defassa or sing-sing (*K. defassa*) occurs in the savannas south of the Sahara and in parts of east Africa. Their long spreading horns curve forward at the tips. The lechwes are smaller than the waterbucks, with long sinuous horns. There are two species: *K.* (*Adenota*) *megaceros*, almost black with white withers, is found in the upper Sudan, and *K.* (*Adenota*) *leche* occurs in central Africa and is reddish. The kobs, *Kobus* (*Adenota*), have short sinuous or lyrate horns; they are reddish in colour, sometimes with white facial markings. Kobs are widely distributed in Africa except for forests and deserts. The reedbucks (*Redunca*) have short tails, small lateral hoofs and, like the preceding species, have a bare spot below the ear. The shoulder height varies from 28 to 37 in. A small species, the mountain reedbuck (*R. fulvorufula*), is found in mountainous parts of east and south Africa, and the common reedbuck (*R. arundinum*) is found over most of Africa south of the Sahara. The South African gray or vaal rhebok (*Pelea capreolus*) is distinguished by its gray woolly hair and its rather long, spikelike horns.

W. SUSCHITZKY

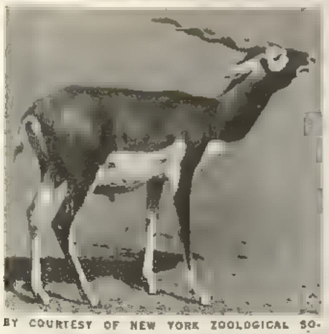
FIG. 2.—DEFASSA OR SING-SING WATERBUCK (KOBUS DEFASSA)

Hippotragini.—The Hippotragini are generally large antelopes with long horns, straight, backward curving or, in one species, spirally twisted, present in both sexes. *Hippotragus* includes the extinct blaaubok, the roan antelope and the sable antelope. In it the horns rise nearly vertically above the eyes, then sweep backward in a bold scimitarlike curve. The roan antelope (*H. equinus*) is a large species, with stout and comparatively short horns, and of reddish-gray colour. Roan antelopes are widely distributed over the greater part of Africa south of the equator, excluding the rain forests of the equatorial zone. The blaaubok of South Africa was similar in appearance but was blue-gray in colour. The sable antelope (*H. niger*) is rather smaller than the roan, but its horns are longer, especially in the Angolan race, in which they may reach 64 in. in length. Sable antelopes are distributed over a large part of central and east Africa. *Addax*, with spiraling horns, contains a single desert species (*A. nasomaculatus*) found in north Africa from Senegal to Dongola. The gemsbok (*Oryx gazella*) and the

beisa (*O. beisa*) have nearly straight horns and are very similar except for the larger size of the former. The gemsbok inhabits southwestern Africa from the Kalahari desert to Angola and the beisa is found from the Red sea to northern Tanganyika. The very pale Arabian oryx (*O. leucoryx*) has straight horns; the north African scimitar-horned oryx (*O. algazel*) is also almost white, but its horns curve backward in a wide sweep.

Alcelaphini.—The tribe Alcelaphini contains the hartebeests, the blesbok, sassaby, tiang and the gnus. They are large antelopes, usually somewhat grotesque and ungainly in appearance, with horns in both sexes. The hartebeests (*Alcelaphus*) are characterized by their long faces and high horn pedicle; the horns, which are lyrate and more or less strongly ringed, rise almost vertically from the cylindrical pedicle. The neck is unmaned and the tail is moderately long; the height of the withers (43–54 in.) greatly exceeds that of the hindquarters. Several subspecies of hartebeests are recognized. The bubal (*A. buselaphus buselaphus*) of north Africa is nearly or quite extinct in typical form. A large race comes from the Senegal-Republic of Mali area. The lelwel (*A. b. lelwel*) has a high forehead; the horns are close together with the tips directed posteriorly. It occurs in the Sudan, and closely allied forms are found in Uganda and northern Kenya. Coke's hartebeest (*A. b. cokei*), with widely lyrate horns, is found on the plains of northern Tanganyika and southern Kenya. The tora (*A. b. tora*) is more richly coloured and occurs from Eritrea to the Blue Nile, but Swayne's hartebeest (*A. b. swaynei*) differs in having the face and upper forelegs black. These subspecies occasionally interbreed where their ranges overlap. The Cape hartebeest (*A. b. caama*) resembles the lelwel but is reddish in colour, with face and outsides of the limbs black. Lichtenstein's hartebeest (*A. lichtensteini*), found from Mozambique and northern Rhodesia to southern Tanganyika, is a pale species with short twisted horns. In *Damaliscus*, the bastard hartebeests, the withers are generally less elevated and the horns rise from the head. The hirola, or Hunter's hartebeest (*D. hunteri*), has a white chevronlike marking on the forehead; it is found only on the north side of the Tana valley in Jubaland, east Africa. The bontebok (*q.v.; D. dorcas dorcas*) and blesbok (*D. d. phillipsi*) are two closely allied South African forms which once existed in countless thousands but have been reduced to a few herds preserved on various farms in South Africa. The sassaby, or tsesebe (*D. lunatus*), is distributed over a large area of southeast Africa from the Orange river to Northern Rhodesia and Nyasaland. The gnu, or black wildebeest (*Connochaetes gnou*), differs from the hartebeests and their allies in the presence of tufts of hair on the face, a well-developed mane, a horselike tail and a very broad muzzle. As a truly wild animal this species no longer exists; formerly it was widely distributed over the plains of Cape Colony and the Orange Free State. The brindled gnu, or blue wildebeest (*C. taurinus*), is distinguished from the black wildebeest by the smaller hindquarters and higher withers and the horns spreading out laterally instead of curving forward over the face. The various races of brindled gnu range over a large part of central Africa from Kenya to south of the Zambezi.

Subfamily Antilopinae.—The subfamily Antilopinae is subdivided into two tribes, the Neotragini and the Antilopini.



BY COURTESY OF NEW YORK ZOOLOGICAL SOCIETY

FIG. 3.—BLACK BUCK (ANTILOPE CERVICAPRA)

Neotragini.—The Neotragini includes the klipspringers, oribis, dik-diks and pygmy antelope, all of which are small, delicately formed species, only the males of most kinds possessing horns. The klipspringer (*Oreotragus oreotragus*) is distinguished from its relatives by its coarse, brittle hair and narrow, high hoofs. Several races are widely distributed over the more mountainous parts of Africa from Ethiopia to Cape Province. The oribis (*Ourebia*) have a bare glandular patch beneath each ear; lateral hoofs are present and horns are slender and ringed basally. The grysbok (*Raphicerus melanotis*) and the other relatives lack the bare patch beneath the ear. The grysbok has a reddish-speckled coat and small lateral hoofs; it extends from the Cape as far north as the Zambezi and Mozambique. The steinbok (*Rhaphicerus campestris*) resembles the grysbok but lacks the lateral hoofs and its colour is a more pronounced buff. This species is found from South Africa to Angola and Mt. Elgon in east Africa. The suni (*Nesotragus*) stands only 13 or 14 in. at the shoulder and males possess slender, relatively long horns (up to 5 in.), which are strongly ringed. The various species and races are confined to east Africa from Zululand to Zanzibar. In the pygmy antelopes (*Hylarnus*) the shoulder height is about equal to that of the sunis, but the horns are smaller and nearly smooth; the genus is confined to west and equatorial Africa. The royal antelope (*Neotragus pygmaeus*), the only member of the genus, is only about ten inches high, being the smallest of all true ruminants; the horns are very small and unringed. This species inhabits the west coast from Liberia to southern Nigeria.

AUTHENTICATED NEWS

FIG. 4.—IMPALA (AEPYCEROS MELAMPUS)

The dik-diks (*Madoqua*) have a tuft of long hair on the crown and a more or less marked elongation of the snout; in the most extreme species this is almost a proboscis. The various species stand 13 or 14 in. high at the shoulder and are confined to east Africa from Ethiopia to Tanganyika, with another isolated species in Angola and South-West Africa. The beira (*Dorcatragus megalotis*) is larger than the dik-diks, measuring about 23 in. in height. The ears are extremely large, and the horns, which are spikelike and ringed basally, measure four to five inches in length. The beira is found only in Somalia and Ethiopia.

Antilopini.—The Antilopini comprise the black buck, the gazelles, the gerenuk, the springbuck, the impala and the dibatag. The black buck (*Antilope cervicapra*), confined to India, is recognized by the long, spirally twisted horns of the males, whose bodies are blackish with white markings. The females are buff. The gazelles (*Gazella*) are widely distributed over western and central Asia, peninsular India and northern and eastern Africa. Horns are present in both sexes, but the females of one Asiatic gazelle are hornless. Some of the African species are of fairly large size, standing 34 to 35½ in. at the shoulder. The springbuck (*Antidorcas marsupialis*) is distinguished from the gazelles by the presence on the middle line of the loins of an eversible pouch lined with long white hairs capable of erection. When alarmed, the springbuck turns the pouch inside out, exposing the white hairs. The range includes South Africa as far north as the Zambezi and Angola. The gerenuk (*Lithocranius walleri*) is at once distinguishable from the other members of the subfamily by the great elongation of the neck and legs. This species is found from Somalia to northern Tanganyika. The dibatag (*Ammodorcas clarkei*), a long-necked gazelle with short, forward-curving horns like those of the reedbuck, is found only in Somalia. The impala (*Aepyceros melampus*) is characterized by the splendid lyrate horns of the males and the absence of lateral hoofs. It ranges over a considerable part of Africa, as far north as Angola in the west and Kenya in the east. *See* also references under "Antelope" in the Index. (L. H. M.)

ANTENNA (AERIAL), a component of an electromagnetic system (such as radio, television, radar, direction finding) used for radiating electromagnetic waves from a transmitter or for intercepting and feeding them to a receiver, or both. When an

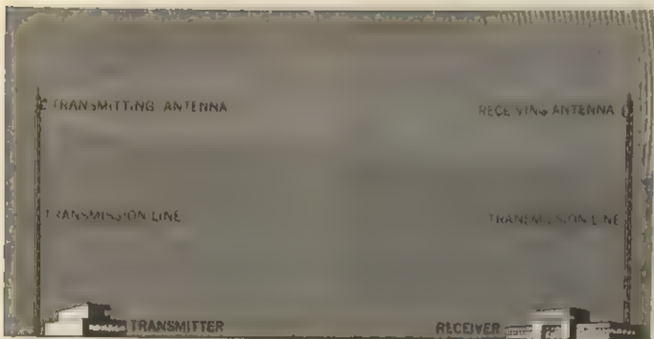


FIG. 1.—SCHEMATIC DIAGRAM OF AN ELECTROMAGNETIC COMMUNICATION SYSTEM

antenna is used for radiating, the energy is fed to it by a transmission line connected to the transmitter (*see* fig. 1). When used as a receiver, the antenna intercepts a portion of the energy radiated by the transmitting antenna and feeds it into a transmission line leading to the receiver. An antenna has identical transmitting and receiving properties and may be used simultaneously for transmitting and receiving. The performance of any electromagnetic communications system, including radio, television, radar and telemetering, is influenced to a large extent by the antennas used. For example, the accuracy with which a radar system determines the position of an object depends in part on the type of radiation pattern produced by the antenna. (*See* RADAR: *Antennas and Scanners.*)

Antennas are described according to their: (1) function in the system, whether transmitting or receiving; (2) use, such as bombing, telemetering, beacon, direction finding, television, radio, radio telescope or guidance; (3) shape, for example: parabolic, rhombic, vee or helical; (4) radiation pattern, whether omnidirectional, directive or cosecant beam; and (5) frequency of the signal used in operation: high frequency (HF), very high frequency (VHF) or ultrahigh frequency (UHF).

As an example of difference of function, television receiving antennas differ substantially from the television transmitting antennas since the transmitting antennas must be capable of handling power in kilowatt quantities and of radiating it in all directions, whereas television receiving antennas must handle power in microwatt amounts and receive from selected directions. In one case the antenna must be relatively omnidirectional, in the other case relatively directional.

The requirements of a given electromagnetic communication system together with the frequency of the signal determine the type of transmitting and receiving antenna to be used. On the radiobroadcast band the wave length is very long, with the signal frequency in kilocycles. Wave length (λ) in feet is obtained by dividing the velocity of light (984×10^6 ft. per second) by the frequency in cycles per second. For example, a radio transmitter operating at 1,000 kc. per second transmits electromagnetic energy with a wave length of 984 ft. This long wave length, to a large extent, limits the transmitting antenna to a vertical metal tower approximately one-fourth of a wave length in height. In most radio installations a counterpoise of radial wires is embedded in the ground under the antenna. Usually the energy is radiated equally in all horizontal directions (omnidirectional in the transverse planes). However, if the energy is to be directed in a preferred general direction (directive antenna), two or more such towers are used. Radio receiving antennas commonly are in the form of long wires or "whips" such as automobile antennas. These are very short in terms of a wave length and have very low efficiency.

FIG. 2.—TELEVISION RECEIVING ANTENNAS: (A) YAGI; (B) DOUBLE VEE; (C) FOLDED DIPOLE

At television signal frequencies the wave length is between 1 ft. and 17 ft., permitting greater leeway in the design of both transmitting and receiving antennas, especially at the higher frequencies (shorter wave lengths). The television transmitting antenna is mounted at an elevated site or on the top of a tower in order to increase the distance at which its signal can be received. In the vertical plane the television transmitting pattern is directive, and an attempt usually is made to direct the energy below the horizon in order not to waste energy by sending it upward into space. (Unlike waves at radiobroadcast frequencies, television waves are not reflected back to earth by the ionosphere, and thus reception normally is not possible beyond the horizon as viewed from the transmitting antenna.) In the transverse plane the television radiation pattern is omnidirectional. Near the transmitting antenna the receiving antenna usually is an indoor type because of the comparatively high strength of the signal. At greater distances rooftop antennas predominate; and at still greater distances, very directive antennas pointed in the general direction of the transmitter are used. Typical examples of rooftop or chimney-mounted television receiving antennas are the yagi, double vee and folded dipole (fig. 2). (*See* BROADCASTING: *The Broadcast Transmitter* and *The Broadcast Receiver.*)

In radar the same antenna is used for transmitting and receiving. The type of antenna selected depends on the purpose of the radar system; that is, whether it is used for searching, bombing, tracking, etc. The radiation patterns of these antennas are normally very directive or flared beams. Because of the high operating frequencies, many types of antennas are possible.

Radiation Pattern and Gain.—If it were possible to radiate electromagnetic energy from a geometric point (point source), the electromagnetic field would have constant amplitude on the surface of a sphere whose centre was the point source. Such an ideal radiator is called an isotropic radiator and its gain or directivity is zero. Hence, it is used as a reference for gain or directivity.

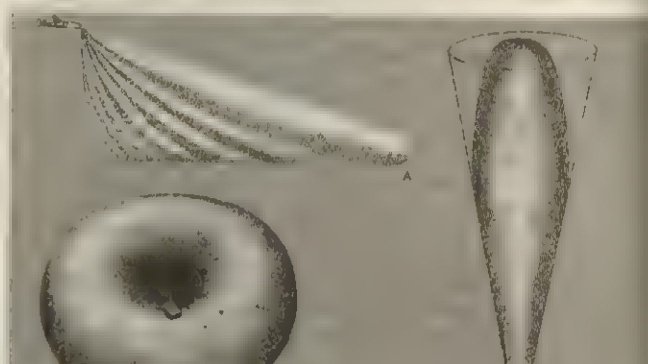

FIG. 3.—RADIATION PATTERNS: (A) SHAPED BEAM; (B) HALF-WAVE DIPOLE ANTENNA, MOUNTED VERTICALLY; (C) DIRECTIVE RADIATION PATTERN

The radiation pattern of a half-wave transmitting dipole (fig. 3[B]) has a gain in reference to isotropic of 2.2 decibels (db). (The gain in decibels equals 10 log P_2/P_1, where P_1 is the power radiated in a given direction from the reference antenna and P_2 is the power radiated in the same direction by the antenna being compared; this unit is borrowed from acoustics, where a decibel is considered as a readily distinguishable change in the intensity of a sound.) The radiation pattern of the dipole is directive in all planes containing the dipole and omnidirectional in all planes perpendicular to the dipole. The gain or directivity of an antenna increases as the energy is concentrated into a cone, with the maximum energy at the axis of the cone (fig. 3[A]); the smaller the vertex angle of the cone the greater the gain. In directive antennas (pencil beam antennas) there is energy outside this cone and if

the radiation pattern is plotted in polar co-ordinates, it will be found to have one dominating lobe (the main lobe) and a number of smaller lobes (side lobes). Hence, it is desirable to have as little energy as possible in the side lobes. Of course, the cross section of the ellipse need not always be circular because it may be desirable (as in search antennas) to have the cross section elliptical so that the beam is flared in one plane and very directive in the orthogonal plane. Again, the beam may be directive, for example, in the horizontal plane and shaped (fig. 3[C]) in the vertical plane in order to distribute the energy as a function of distance (a bombing antenna employs this type of beam). Also, there are antennas, such as those for television transmission, that require an omnidirectional pattern in one plane and a directive pattern in the perpendicular plane.

ANTENNA COMPONENTS

An antenna may consist of a single radiating element, a composite of radiating elements or a radiating element and a reflector.

Single Radiating Elements.—There are numerous types of radiating elements. The most common are (fig. 4) the dipole, loop, helix, electromagnetic horn and slot.

Dipole.—Considered as the fundamental radiator, the dipole consists of two collinear conductors, fed in phase opposition; *i.e.*, one half positive when the other is negative, and vice versa. The classical dipole is one-half wave length long. The radio transmitting tower is in effect a dipole, the other half being the electrical "image" in the counterpoise. This type is also referred to as a monopole. The half-wave dipole, or doublet, is used extensively as a reference antenna. Numerous directive antennas consist of an array of dipoles or a reflector with a dipole as the feeding element.

An important property of a dipole is that it is linearly polarized. The electric vector radiated by a dipole is parallel to the dipole; a receiving dipole aligned at right angles to the transmitting dipole would receive little or no energy from this radiated field. This condition is due to the fact that the electromagnetic field radiated by a dipole consists of electric and magnetic fields at right angles to each other with the magnetic field perpendicular to the direction of propagation. Since this field is linearly polarized, another use for a dipole is to check the polarization of a radiated field. (*See* ELECTROMAGNETIC WAVES.)

Loop Antenna.—Wire formed into an incomplete circle or square and fed in phase opposition at the discontinuity is called a loop antenna. It is popularly used in direction finding. (*See* NAVIGATION: *Radio Direction Finders.*)

Helical Antenna.—If a conductor forms a helix with the proper pitch and diameter, it will radiate in the direction of the axis of the helix. This relatively directive antenna radiates a circularly polarized field. If the electric vector rotates in the plane orthogonal to the direction of propagation, the electromagnetic field is called circularly polarized provided its amplitude is constant throughout its rotation. However, if it increases, then decreases and increases again, the field is said to be elliptically polarized.

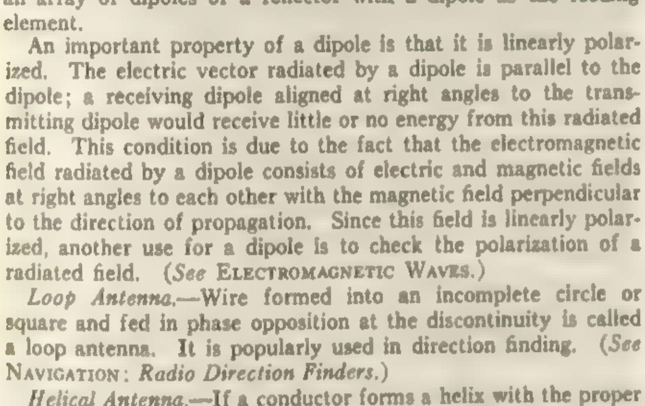

FIG. 4.—RADIATING ELEMENTS (*See* TEXT)

The helix is often used as a receiving antenna for radiated energy of unknown polarization and when the orientation of the linearly polarized field is varying. Similar to the dipole, it has been used to feed reflectors and as the radiating element in directive arrays.

Electromagnetic Horns.—If the sides of a wave guide are flared, it forms an electromagnetic horn. (Wave guides frequently are used in place of transmission lines to guide the electromagnetic field at microwave frequencies.) Horns generally are hollow rectangular tubes flared in one or both planes. If flared in one plane, the wave guide is called a sectoral horn; if flared in both planes, it is called a pyramidal horn. The radiation pattern of a horn depends on its flare and length. Horns can be used by themselves as directive antennas or as feeding elements in parabolic antennas.

Slots.—If a slot is cut out of a metallic sheet and fed at the centre of its longer sides, it forms a slot antenna. The slot may be in the shape of a rectangle, L, dumbbell, ring or cross. Like the dipole, the radiation pattern of a rectangular slot is linearly polarized. Radiation from a horizontal slot is vertically polarized, while that from a vertical slot is horizontally polarized, in contrast to a dipole, where the radiation from a vertical dipole is vertically polarized and from a horizontal dipole is horizontally polarized. The slot antenna is used extensively on aircraft and missiles when projections from the surface are not feasible. Slots

FIG. 5.—ARRAYS: (A) RECTANGULAR DIPOLE ARRAY. (B) LINEAR SLOT ARRAY

also can be formed into arrays for directive antennas.

Long-Wire Antennas.—There are two important long-wire antennas used for point-to-point communications; namely, the vee and rhombic. Both give directive radiation patterns.

Combination Radiating Elements.—*Arrays.*—A coplanar set of radiators is called a linear array. A coplanar parallel set of linear arrays forms a rectangular array. The radiation pattern of a linear array is determined by the fundamental radiation pattern of the individual elements forming the array as well as by the spacing between the elements and the amplitude and the phase of the input power. Arrays are designated according to the direction of the axis of their main lobe with respect to the array: broadside if perpendicular to the array, end fire if in the direction of the array, and arbitrary angle if the direction is intermediate between end fire and broadside.

Radiating elements used most frequently in linear arrays are dipoles (fig. 5[A]) and slots (fig. 5[B]). In general, the radiation pattern from a linear array is omnidirectional in the planes transverse to the array. To make the radiation pattern directive in the transverse planes, a set of arrays is used to form a rectangular array. Broadside rectangular arrays are used extensively as radar antennas in the VHF band. Arrays permit much leeway in forming the radiation pattern. They can be made to give a sharp pencil beam, a beam fanned in one plane and very directive in the orthogonal plane or a beam shaped in one plane and very directive in the orthogonal plane.

Reflectors.—A plane sheet, two sheets at right angles or a parabola are commonly used to increase directivity (fig. 6). A broadside rectangular array gives a directive beam in opposite directions. However, if a perfectly conducting plane sheet is placed behind the array at a distance of approximately one-quarter wave length, the energy is reflected forward, increasing the directivity of the antenna. A dipole or an array of dipoles with a corner reflector (fig. 6[A]) forms a directive array. Parabolas (fig. 6[B]) are universally used for very directive antennas in point-to-point communications, microwave relays, radar antennas and radio telescopes. The feeding element, a dipole or electromagnetic horn, is placed at the focus of the parabola. Radial rays emitted from the focus are reflected in parallel rays by the pa-

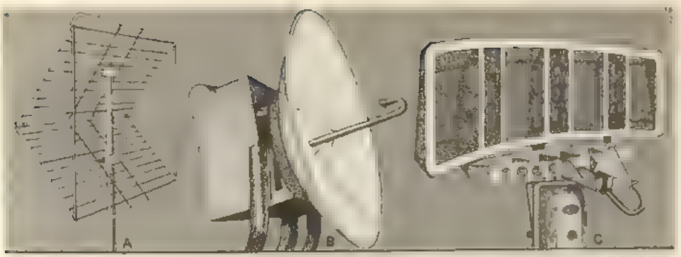

FIG. 6.—REFLECTORS: (A) CORNER REFLECTOR; (B) PARABOLIC REFLECTOR; (C) CURVED REFLECTOR FOR RADAR

rabola, thus producing a very directive radiation pattern with the maximum of the radiation pattern in the direction of the axis of the parabola. Actually, a paraboloid of revolution is used and if the feeding element is moved off the axis, the beam is tilted. If the displaced feeding element is rotated about the axis of the paraboloid and if the return signals, when the feeding element is at diametrically opposite positions, are electronically compared, a very accurate determination of the position of the target may be made. A reflector may be shaped so that a beam is flared or shaped in one plane and is very directive in the perpendicular plane. A curved reflector (fig. 6[C]) is commonly used to obtain shaped beams for ground-based, ship-borne and air-borne radar antennas.

ANTEROS (ANTHERUS), **SAINT** (d. 236), pope for several weeks at the end of 235 and the beginning of 236. According to the *Liber Pontificalis,* he was martyred for having ordered a collection of the acts of the martyrs to be made and included in the archives of the church. The site of his burial in the catacombs was discovered by G. B. de Rossi in 1854. His feast day is Jan. 3.

ANTHEIL, GEORGE (1900–1959), U.S. composer known for the ultramodern music he wrote in the 1920s, was born in Trenton, N.J., July 8, 1900. He studied with Ernest Bloch in New York city; in 1921 he went to Europe and gave piano recitals. In Paris he became prominent in the literary and artistic circles of the avant-garde; Ezra Pound published a book about him, *Antheil and the Treatise on Harmony* (1924; with supplementary notes, 1927). His *Ballet mécanique,* scored for mechanical pianos, automobile horns, electric bells and airplane propellers, produced a sensation in Paris (June 19, 1926) and in Carnegie hall, New York city (April 10, 1927). His later works were less eventful; he wrote six symphonies; the operas *Transatlantic* (1930), *Helen Retires* (1934), *Volpone* (1953), *The Brothers* (1954) and *The Wish* (1955); chamber music; and an autobiography with the eloquent title *Bad Boy of Music* (1945). He died in New York city, Feb. 12, 1959. (N. SY.)

ANTHELMINTICS are drugs that act against helminths (worms) and are used to treat worm infections. The term vermifuge is often applied to remedies used to remove intestinal worms. Although the term vermicide is sometimes used for such drugs, very few justify this name since only rarely do they directly kill the parasites. None of the anthelmintics in use is completely effective against the worms or completely without toxic effect upon the host, particularly if taken in overdoses. Furthermore, none of the anthelmintics known is equally active against all worms. The search for better anthelmintics was intensified after World War II, and new and more effective drugs are regularly introduced, largely replacing the earlier carbon tetrachloride, gentian violet, oil of chenopodium, pelletierine, quassin, santonin and thymol. Several antibiotics show activity in the laboratory against some worms.

Intestinal worms are in general more effectively treated than others, since they need not be killed but merely eliminated. Some anthelmintics must be followed within an hour or two by a purgative, to remove both the injured worms before they recover and the drug, which may result in uncomfortable side effects.

The anthelmintic piperazine paralyzes certain species of intestinal worms, while exhibiting little toxic effect upon man or domesticated animals. It is very effective against the large intestinal roundworms, *Ascaris lumbricoides,* of man, and against the adult pinworm, *Enterobius vermicularis.* However, since it is less effective against immature pinworms, it is desirable to repeat the treatment a week to ten days later. Piperazine is also very effective against the ascarids of domesticated animals and against the pinworms of horses. However, it has little action against other intestinal worms in man or in domesticated animals.

Tetrachloroethylene has been used for the treatment of hookworm infection in man and of some of the intestinal parasites of domesticated animals. Quinacrine hydrochloride (Atabrine or Mepacrine), the World War II antimalarial drug, is used for treatment of tapeworm infections of man and of dogs; aspidium (male fern) is also used. Other drugs used in the treatment of intestinal worms in man and domesticated animals include arecoline hydrobromide, *n*-butyl chloride, β-naphthol, phthalofyne and toluene. Organic tin compounds are used to treat tapeworm infections in poultry. In the treatment of cattle such drugs as phenothiazine are used extensively in feed or in salt to decontaminate pastures and prevent reinfection. Phenothiazine interferes with the egg laying of the worms and with the development of the young worms from the eggs.

The treatment of worms in tissues or organs other than the intestine is more difficult than the treatment of intestinal worms, since they must be killed or critically injured by the treatment so that they may be destroyed and absorbed within the body. Furthermore, anthelmintics for such worms must either be injected into a vein or muscle or be absorbed from the intestine, with greater danger if the drugs are toxic. Drugs used include chloroquine, gentian violet, diethylcarbamazine citrate, lucanthone hydrochloride (Miracil D) and organic compounds of antimony or arsenic.

ANTHEM, derived from the Greek *antiphona,* through the Saxon *antefn,* a word that originally had the same meaning as antiphon (*q.v.*). Although only an optional part of the Anglican morning and evening services and of certain other Protestant services, the anthem has been developed in England as a free type of musical composition since 1545. Its text is often biblical, but there have always been numerous examples of the use of other texts, both verse and prose.

The musical resources needed for the performance of an anthem have never been standardized: at first unaccompanied choral writing (full anthem) was the norm, but the growth in the 16th century of the verse anthem (which made extensive use of a solo vocal part, and eventually of many soloists) encouraged the use of instrumental accompaniment. The organ was clearly the first choice for this subsidiary though frequently important part, but there were many verse anthems provided with an elaborate accompaniment for an instrumental group such as viols or wind instruments. Shortly after the Restoration it was common, at least in the royal chapel, to perform anthems with orchestral accompaniment. In the 18th century the organ returned to favour, and the full anthem ousted to some extent the complex verse anthem, though solo passages were occasionally introduced for special effect.

Both full and verse anthems exploited the practice of antiphony between two sides of a choir, usually referred to as decani (the south, or dean's side) and cantoris (the north, or precentor's side). The alternation of these two sections of the choir, and those subsections specially designated in the more elaborate type of verse anthem, provided a subtle effect of fluctuating timbre and sonority

that often reflected the mood or sense of the text. In the 19th and 20th centuries not only church music composers but those whose main activities lay in other spheres have written anthems for use (to quote the Book of Common Prayer) "in choirs and places where they sing." *See* CHURCH MUSIC.

ANTHEMION, a conventional design consisting of a number of radiating petals, developed by the Greeks from the Egyptian and Asiatic form known as the lotus palmette. One of the most fertile sources of decorative ornament, it was not only used widely by the Greeks and Romans but occurs also in Byzantine and Romanesque examples and is common in modern work. Used first by the Greeks as a decoration on painted pottery, it was soon

(LEFT) "ARCHITEKTONISCHEN ORDNUNGEN DER GRIECHEN UND RÖMERN," (ERNST UND KORN); (RIGHT) ALISON FRANTZ

(LEFT) PALMETTE ANTHEMION; (RIGHT) ALTERNATING LOTUS AND PALMETTE ANTHEMIA, FROM DETAIL OF FRIEZE ON SOUTH WALL OF ERECHTHEUM

adapted to architecture. The single palmette form is used for acroteria, antefixes and the top of vertical steles. The continuous pattern of alternating lotus and palmette springing from connecting spirals decorates especially the cymatium of the cornice. Although sometimes only painted, the majority of anthemia are molded or carved in relief.

ANTHEMIUS (d. 472), Western Roman emperor from April 12, 467, to July 11, 472, son-in-law of the emperor Marcian, was appointed by the Eastern emperor Leo I with a view to their uniting against Gaiseric and the Vandals of Africa. The patrician Ricimer (*q.v.*), all-powerful in Italy, was won over by an arrangement that he should marry Anthemius' daughter Alypia, but because Anthemius was a Greek and a philosopher, he was suspected of wishing to restore paganism and his high standard of justice added little to his popularity in Italy. Ricimer and he soon quarreled and in 472 the patrician besieged him in Rome, where the emperor's forces were defeated. Anthemius in disguise mingled with the beggars at the church of St. Chrysogonus, but was found and beheaded. He is the subject of a panegyric by Sidonius Apollinaris.

See J. B. Bury, *History of the Later Roman Empire*, vol. i (1923). (E. A. T.)

ANTHEMIUS OF TRALLES (fl. 6th century A.D.), Greek mathematician and architect, who with Isidorus of Miletus and under the patronage of Justinian planned and built the church of Hagia Sophia in Constantinople. He came from an eminent family. His father, Stephanus, was a physician and his brother Alexander was the last great medical author of antiquity. The plans for Hagia Sophia were original and daring. Started in 532, it was finished in 537, but in 558, after the death of Anthemius, it had to be restored, following the collapse of the dome.

In *Concerning Remarkable Mechanical Devices*, he dealt with burning mirrors and gave the first instance on record of the practical use of the directrix. Setting out to construct surfaces to reflect to one and the same point (1) all rays in whatever direction passing through another point and (2) a set of parallel rays, he assumed a property of an ellipse not found in Apollonius (the equality of the angles subtended at a focus by two tangents drawn from a point); and, having given the focus and a double ordinate, he used the focus and directrix to obtain any number of points on a parabola. (C. A. MO.)

ANTHESTERIA, one of the four (or five) Athenian festivals in honour of Dionysus, held annually for three days (11th–13th) in the month of Anthesterion (February–March). Its object was to celebrate the maturing of the wine stored at the previous vintage, and the beginning of spring. On the first day, called Pithoigia (opening of the casks), libations were offered from the newly opened casks to Dionysus, all the household joining in the festivities. The rooms and the drinking vessels in the homes were adorned with spring flowers, as were also the children over three years of age. The second day, named Choes (feast of cups), was a time of merrymaking. The people dressed themselves gaily, some in the disguise of the mythical personages in the suite of Dionysus, and paid a round of visits to their acquaintances. Others poured libations on the tombs of deceased relatives. On the part of the state, this day was the occasion of a peculiarly solemn and secret ceremony in one of the sanctuaries of Dionysus in the Lenaeum, in which the *basilinna*, wife of the *archon basileus* (king archon), went through a ceremony of marriage to Dionysus. On these days, it was believed, the souls of the dead came up from the underworld and walked abroad; people chewed leaves of whitethorn and smeared their doors with tar to protect themselves from evil. The third day was named Chytroi (feast of pots), a festival of the dead. Cooked pulse was offered to Hermes, in his capacity of a god of the lower world, and to the souls of the dead. J. E. Harrison believes that the entire festival was originally a great annual ceremony for the exorcism of the spirits of the dead; but that through confusion of burial cask/wine cask, and funeral libation/drinking libation, it came to be considered a festival of Dionysus. (T. V. B.)

ANTHOLOGY, a collection of short pieces or extracts usually from different authors, especially in verse, and usually of literary value. An anthology may consist of the best or the most representative work of given national groups (Edith Sitwell, ed., *The Atlantic Book of British and American Poetry*, 1958; Louis Untermeyer, ed., *The Britannica Library of Great American Writing*, 1960), of a period (Norman Ault, ed., *Elizabethan Lyrics*, 1949), of a school of poetry (Amy Lowell, ed., *Some Imagist Poets*, 1915, 1916, 1917) or of a literary kind (*The Best American Short Stories*, annual since 1915), and occasionally of an author (Harry Levin, ed., *The Portable James Joyce*, 1947); or it may consist of pieces all related to a given theme or subject (Walter Blair, ed., *Native American Humor, 1800–1900*, 1937) or taken from a particular periodical (Edward Weeks and Emily Flint, eds., *Jubilee: One Hundred Years of the Atlantic*, 1957). Annual publishers' lists demonstrate the enduring popularity of this long-established form which serves as a convenient and adaptable framework into which can be fitted a variety of material. Some anthologies have considerable literary significance in themselves, an example being Tottel's *Miscellany* (1557), in which were published for the first time the major poems of Sir Thomas Wyat and Henry Howard, earl of Surrey; some are historically significant as reflecting or forming the taste of their age, as Francis Palgrave's *Golden Treasury* (1861), a well-known Victorian anthology; and some have preserved works that might otherwise have been lost (for examples in Arabic literature *see* HAMASAH; MU'ALLAQAT; MUFADDALIYAT; and most of the Middle English lyric poetry now extant survived in collections of one kind or another). In modern times anthologies often serve to introduce new and unknown writers, as in *Five Young American Poets* (three series, 1940, 1941, 1944) and similar works which appear from time to time.

The "Greek Anthology."—The term anthology originally denoted a garland or collection of flowers (Gr. *anthologia*, Lat. *florilegium*), and hence a selection of choice pieces tastefully arranged, as in the *Garland* of Meleager which formed the basis for the best known of anthologies, the *Greek Anthology*. This is

the modern title of a collection of Greek epigrams, mostly in the elegiac couplet, together with some other pieces of lesser interest, dating from about 700 B.C. to A.D. 1000 or later. The history of the *Anthology* is a history of anthologies. Meleager's *Garland,* compiled in the early part of the 1st century B.C., contained, besides a number of his own epigrams, the work of 50 or more other poets from the earliest period to his own day; this is incorporated into the modern *Anthology* and is, all in all, its most valuable part. A similar *Garland* of later poets was compiled by Philippus of Thessalonica (1st century A.D.), and a third, which for the first time was called an *Anthology,* by Diogenianus (2nd century). The poems in each of these collections were arranged alphabetically by the initial letter of the opening line. The first collection in which the poems were arranged by subject was the *Circle* of Agathias (later 6th century), to which the compiler contributed some poems of his own and of others "a small portion, enough for a taste." All of these anthologies were incorporated into a larger collection by Constantinus Cephalas (late 9th century), who added to them extracts from the works of single authors. Shortly thereafter (around A.D. 980) the Cephalas version was further augmented and revised; this revision (discovered in 1606–07 in the library of the elector palatine at Heidelberg and known as the Palatine manuscript) constitutes the first 15 books of the *Anthology* in modern editions. The 16th and final book in modern editions consists of some additions from yet another manuscript version of Cephalas (the Planudean manuscript), compiled in 1301 and containing some epigrams not included in the Palatine manuscript.

The value of the *Anthology* lies in the distinction and charm of perhaps one-sixth of the whole. For the rest, it preserves a good deal that is of historical interest; it illustrates the continuity of Greek letters for almost 2,000 years, since the works of the latest period are in language, style and feeling not too distinct from the works of the earliest; and it has had a persistent and considerable influence on later literature. There are, for example, translations and imitations in Latin from the time of Quintus Lutatius Catulus (early 1st century B.C.) to the time of Decimus Magnus Ausonius and Claudius Claudianus (late 4th century A.D.). The modern influence begins with the publication of the Planudean manuscript in 1494. For the next century and a half there were countless versions and variations of Greek epigrams in Latin; those of Hugo Grotius (1583–1645) are generally regarded as the best. The influence on the vernacular literatures, especially on Italian and French, was most extensive in the period from 1550 to 1610; it usually came, however, not directly from the Greek text but by way of the contemporary poetry in Latin which was based on the *Anthology.* Thus Joachim du Bellay's (1522–60) *Voeu d'un vanneur de blés aux vents* was derived from a Latin version by the Venetian Andrea Navagero (1483–1529) of *Anthology* 6:53. In the criticism of the time the vernacular sonnet and madrigal were often considered the equivalents of the epigram in Greek and Latin so that the theory of the lyric became largely a theory of the epigram. With the development in the 17th and 18th centuries of a taste for the point and wit represented by the Latin epigrammatist Martial, the influence of the *Anthology* declined; in fact, the expression *à la grecque,* with reference to the unpointed epigram characteristic of the *Anthology,* became proverbial for something insipid and pointless. There was a revival of interest in the *Anthology* in the 19th century, but later there were a number of translations and imitations of particular poems. Modern renderings into English include those of Dudley Fitts whose *Poems from the Greek Anthology in English Paraphrase* (1956) incorporates two of his collections published earlier. As the title indicates, the treatment is free, and many of the Fitts poems are extraordinarily effective.

Later Anthologies.—Other works of the nature of anthologies existed in antiquity; a late example is the *Selections* of Joannes Stobaeus (5th century A.D.), which consists of a number of extracts in prose and verse, grouped under topics. In Latin there is nothing quite comparable to the *Greek Anthology,* although the Salmasian manuscript, compiled in Africa in the 6th century, is of the same general type. It contains the *Pervigilium Veneris* (*q.v.*) and epigrams ascribed to Seneca and Petronius; in modern editions it is augmented by other fugitive Latin verse and titled *Anthologia Latina* (eds., Alexander Riese, Franz Bücheler and Lommatzsch, 1894–1926). However, anthologies similar to Stobaeus' were common throughout the middle ages and furnished the medieval author with the greater part of his learning. These florilegia consisted of extracts, usually from classical authors, of striking sayings, most often of an ethical nature. Similar collections are found in the vernacular: *Proverbs of Diverse Prophets and of Poets and of Other Saints* (*c.* 1375) contains sayings in Latin, French and English attributed to Seneca and Solomon, among others. The culmination of this type is the Renaissance anthology of Desiderius Erasmus, the *Adagia* (1500–33).

Collections of later lyrics, often anonymous and belonging usually to a certain school of poetry, are represented in the middle ages by the *Carmina Burana* (13th century), a collection of rhymed poems in Latin by the Goliards (*q.v.*), or wandering scholars; and by manuscript Harley *2253* (*c.* 1320), an important collection of the early Middle English period, containing English, French, Latin and macaronic poems. The Renaissance was a great age for anthologies of lyric poetry. Among the best-known collections in English are the *Book of Songs and Sonnets* published by Richard Tottel in 1557 and usually referred to as Tottel's *Miscellany;* and *England's Helicon* (1600), containing poems by Spenser, Sidney, Greene, Lodge and Shakespeare. The anthology that explicitly presents a certain school or group of poets is represented in Germany by Julius Wilhelm Zincgref's *Anhang unterschiedlicher ausgesuchter Gedichten,* printed as a supplement to his edition of Martin Opitz's poems (1624). A later example in French is the famous *Le Parnasse contemporain* (1866, 1871–76). Such anthologies of a contemporary school of poets are quite common and sometimes appear as special issues of a magazine. The usual anthology in the 18th century was either such a *Collection of Poems by Several Hands* (1748–58) as Robert Dodsley's or a selection of "beauties" or "elegant extracts," as in Oliver Goldsmith's *The Beauties of English Poesy* (1767). In the same century appeared the first collections of popular or folk poetry, the best known being Thomas Percy's *Reliques of Ancient English Poetry* (1765).

The typical modern anthology in the sense of a collection of poems of a given period or nation selected for their excellence and representativeness seems to be an invention of the Latin Renaissance. The best-known examples are Jan Gruter's *Delitiae* of the Italian, French, German and Belgian Latin poets (1608–14). With the 19th century this sort of anthology begins to be arranged on chronological principles, showing the historical scope and development of a literature, and the works often include essays of a critical or historical nature: for example, Thomas Campbell's *Specimens of the British Poets* (1819). The standard anthology of lyric poetry in the Victorian period, Francis Turner Palgrave's *Golden Treasury of English Songs and Lyrics* (1861) (which, unlike Campbell and others, is divided into books by subject), fixed the educated taste for the lyric for several generations. It was superseded in general favour by Sir Arthur Quiller-Couch's *The Oxford Book of English Verse* (1900 and 1939); a companion volume, *The Oxford Book of American Verse,* ed. by F. O. Matthiessen (1950), is considered an excellent collection of American poetry. Among other 20th-century anthologies of poetry *The New Poetry* (1917; rev. and enlarged, 1932), edited by Harriet Monroe (*q.v.*) and A. C. Henderson, may be mentioned for its historical importance and Robert Bridges' *The Spirit of Man* (1916) for the excellence of its taste. There are similar anthologies in nearly every language. In fact, the general scope and kinds of modern anthologies can be indicated by an enumeration of the standard Oxford books of verse. There are books of English, American, Australasian, French, Spanish, Portuguese, German, Greek, Latin and medieval Latin verse, among others; books of ballads, carols, Christian verse and light verse; and, finally, books of the 16th-century verse, 17th and so on to modern verse.

BIBLIOGRAPHY.—The *Greek Anthology* is edited by W. R. Paton with text and a good English translation, 5 vol. (1916–18), and in French by Jules Maxime Pierre Waltz, incomplete (1928). The best selection

with text, translation and excellent introduction is by J. W. Mackail, *Select Epigrams from the Greek Anthology* (1890, rev. 1907). Scholars use Stadtmüller's unfinished edition (1894–1906) and the complete edition of Friedrich Dübner and Edme Cougy, pub. by Didot (1864–92). For the influence of the Anthology *see* James Hutton, *The Greek Anthology in Italy to the Year 1800* (1935) and *The Greek Anthology in France, and in the Latin Writers of the Netherlands to the Year 1800* (1946). Charles Homer Haskins, *The Renaissance of the Twelfth Century* (1927), gives some account of medieval anthologies. Useful bibliographies are Frédéric Lachère, *Bibliographie des recueils collectifs de poésies publiés de 1597 à 1700* (1901), and *Anthologies*, Bibliography No. 19, National Book Council (1928). (J. V. C.; X.)

ANTHONY (Antony), **SAINT,** of Egypt (*c.* A.D. 250–355), the first Christian monk, was born in middle Egypt. At the age of 20 he began to practise an ascetic life, and after 15 years withdrew for solitude to a mountain by the Nile, called Pispir (now Der al Memum). In the early years of the 4th century he emerged from his retreat to organize the monastic life of the hermits who imitated him. After a time he again withdrew to the mountain by the Red sea, where now stands the monastery that bears his name (Der Mar Antonios). Shortly before his death he ventured to Alexandria to preach against Arianism.

Anthony is noted for his combats with the hosts of evil. Athanasius says that he was first tempted by thoughts of family joys and duties and of the difficulty of his chosen life, but the Devil, finding argument of no avail and hoping to arouse in him the pride of success, appeared as a cringing black boy admitting that he had been defeated by the saint. At other times the Devil appeared under the guise of a monk bringing him bread during his fasts, or under the form of wild beasts, women or soldiers, sometimes beating the saint and leaving him as dead.

From these psychic struggles Anthony emerged as the sane and sensible father of Christian monachism. The monastic rule that bears his name was compiled from writings and discourses attributed to him in the *Life* (by Athanasius) and the *Apophthegmata Patrum.* The rule is still observed by a number of Coptic Syrian and Armenian monks. St. Anthony's feast day is Jan. 17. *See* Monasticism.

Bibliography.—The Greek *Vita Antonii* is among the works of St. Athanasius; for the almost contemporary Latin trans. *see* Rosweyd's *Vitae Patrum*, in J. P. Migne, *Patrologia Latina*, vol. lxxiii; English trans. by R. T. Meyer, "Ancient Christian Writers" (1950). Accounts of St. Anthony are given by J. H. Newman, *Church of the Fathers* (1931), and Butler-Thurston, *Lives of the Saints* (1956). Discussions of the historical and critical questions will be found in E. C. Butler, *Lausiac History of Palladius*, part i, pp. 197, 215–228, part ii, pp. 9–12 (1898, 1904); and Contzen, *Die Regel des hl. Antonius* (1896). For the modern literature, *see* J. Quasten, *Patrology*, vol. iii (1960).

ANTHONY (Antony), **SAINT,** of Padua (1195–1231), Franciscan friar and saint, a doctor of the church, was born at Lisbon, Port., and baptized Ferdinand. At 15 he joined the Augustinian canons and probably became a priest. He joined the Franciscan order in 1220, hoping to preach to the Saracens and be martyred. Instead he taught theology at Bologna, Montpellier, Toulouse and Puy-en-Velay and won a great reputation as a preacher in southern France and Italy. After an attack of dropsy, he died June 13, 1231, at Arcella, en route to Padua, where he is buried. He was canonized by Gregory IX on May 30, 1232, his feast being kept on June 13. On Jan. 16, 1946, Pius XII declared him a doctor of the church. Padua and Portugal claim him as patron saint. In art he is shown with a book, with a heart, flame or lily, or with the Child Jesus. He is invoked for the return of lost property and is the patron of the poor. Among his authentic writings are sermons for Sundays and feast days, published at Padua, 1895–1913. A series of sermons on the Psalms is considered doubtful; several others are attributed to him without foundation.

Day, *St. Anthony: the Man Who Found Himself* (1957); Sophronius Clasen, *St. Anthony, Doctor of the Gospel,* Eng. trans. by I. Brady (1961). (I. C. By.)

ANTHONY, SUSAN BROWNELL (1820–1906), pioneer leader of the women's suffrage movement in the United States, was born on Feb. 15, 1820, at Adams, Mass. Her work helped to pave the way for the adoption of the 19th amendment (1920) to the federal constitution and the world-wide recognition of human rights expressed in the charter of the United Nations. She taught school, organized temperance societies and, after 1854, devoted her life to the antislavery movement and woman's rights. From 1856 to the American Civil War she served as an agent for the American Antislavery society. In collaboration with Elizabeth Cady Stanton (*q.v.*) she published in New York a liberal weekly, *The Revolution* (1868–70). Demanding for women the same civil and political rights extended to male Negroes by the 14th and 15th amendments, she claimed her right to vote as a person and citizen in 1872. She was arrested, tried and convicted, but refused to pay the fine. From then on she campaigned for a federal women's suffrage amendment through the National Woman Suffrage association (1869–90), through the National American association (1890–1906), and by lecturing throughout the United States. With her close associates she compiled and published a four-volume work, *The History of Woman Suffrage* (1881–1902). In 1888 she organized the International Council of Women and in 1904 the International Woman Suffrage alliance. She died in Rochester, N.Y., March 13, 1906.

ANTHOZOA (*i.e.,* "flower animals"), a group of marine animals belonging to the phylum Coelenterata. Many of them form a strong skeleton known as coral. The term "coral" refers to the hard parts of any coelenterate that secretes a firm skeletal support; most of these forms are Anthozoa, and among them the term "true coral" is applied only to the group Scleractinia. The flower-like shape and brilliant colouring of the soft parts of many species have attracted attention for hundreds of years, and the discovery that they are animals instead of plants, minerals or intermediate organizations did not gain acceptance until long after it was first made, in connection with the precious red coral of commerce, by J. A. de Peyssonel in 1727.

Not all the Anthozoa produce a skeleton. A hard support is lacking in the sea anemones, and, although it is present more often than not, among the other kinds of Anthozoa it does not necessarily form a mass sufficiently compact to retain its shape after the death of the soft parts.

An anthozoan may consist of a single polyp as in the case of a sea anemone; but more frequently a colony is formed, containing a number of polyps permanently united; and it is the skeletons built up by certain of these colonies that constitute coral in its characteristic form. (For a definition of polyp *see* Polyp; *see* also Coelenterata: *Polyp and Medusa.*)

The Anthozoa as a class are distinguished from all other Coelenterata not only by the structure of the individual polyps but also in that none of them at any time during their life history assumes the form of a medusa (jellyfish). The anthozoan individual or colony therefore corresponds to the polyp of any coelenterate that exhibits both polyp and medusa alternately during its life cycle. The anthozoan polyps themselves, though often small, tend to be more muscular and substantial than those of other coelenterates. They are characterized by a body that in principle is a cylinder, closed above and below by two discs of tissue. The upper disc or peristome is encircled by a corona of hollow tentacles and is perforated in the centre by a more or less slit-shaped mouth. Leading inward from the mouth is a flattened tube, the throat, which opens directly into the main cavity of the body (coelenteron). The latter cavity is partially subdivided into alcoves by a series of radially arranged membranous partitions, the mesenteries, some or all of which are inserted along the upper part of their inner edge into the outer wall of the throat. The mesenteries bear along their free edge a marginal thickening of epithelium known as the mesenterial filament; they also carry reproductive organs and muscles. The number and arrangement of the mesenteries as well as the structure of the throat, mesenteries and filaments vary from one group of Anthozoa to another. (*See* Coelenterata: *Structure of a Coelenterate.*)

The symmetry of the anthozoan body presents to the casual observer an external radial appearance similar to that exhibited by the Coelenterata in general. Underlying this external sym-

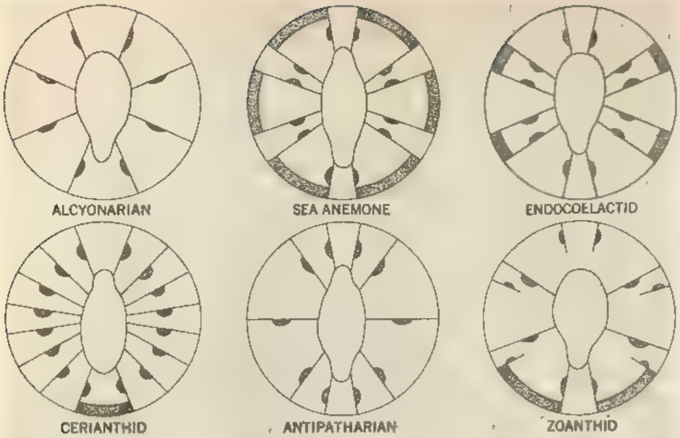

FIG. 1.—TRANSVERSE SECTIONS OF VARIOUS ANTHOZOAN POLYPS SHOWING THE ARRANGEMENT OF MESENTERIES AND ZONES OF GROWTH

Outer circle represents the body wall; thickening on body wall indicates growth zone. Central oval is the throat, with siphonoglyphs indicated as bays. Radial lines represent the mesenteries, the thickening on each being its retractor

metry exists an internal bilateral symmetry so well defined that it is actually possible to divide a polyp into two perfectly equivalent halves along one plane. Much discussion has been aroused by this fact since there is no obvious function for such symmetry. A possible explanation is that the Anthozoa were not always the sedentary, radially arranged creatures they are today. There may have been a phase in their history when they were small creeping animals with definite head and tail ends, upper and lower sides and general bilateral symmetry. When such animals adopted a sedentary life and assumed a radial symmetry, the former bilateral condition would remain as a vestige of the former state of affairs. The bilateral arrangement of parts is very prominent during the early development of a polyp.

An important fact in the development of many Anthozoa is that the wall of the cylindrical body appears to become marked out, after the early stages are passed, into vertical strips, in some of which active differentiation of new parts (or growth direction) takes place; in other zones no new parts are added after a stated amount of structure has been formed (fig. 1). In various groups of Anthozoa the arrangement of the mesenteries in the adult polyp depends on the relationship between the zones of active growth and those in which only a certain amount of differentiation will take place. In other cases no new growth takes place after the early stages, and here a simpler plan of structure consequently prevails.

The axis of symmetry sometimes possesses a distinct significance with regard to the regeneration of parts of an adult polyp. In the sea anemone this axis coincides with a nongrowing zone; and if in a suitable anemone a fragment of reasonable size is cut away from the edge of the animal's base in such a way that the lower ends of the two directive mesenteries that flank the axis lie in its centre, the piece will in many cases regenerate an animal with two heads instead of one. A similar piece containing no directives will regenerate an ordinary one-headed adult.

There are three subclasses of living Anthozoa: (1) the Alcyonaria or Octocorals; (2) the Ceriantipatharia (including cerianthid anemones and the Antipatharia or sea whips); and (3) the Zoantharia. The latter include the Actiniaria (sea anemones), the Scleractinia or madreporarian corals and some obscure groups of solitary and colonial forms resembling sea anemones. In this article only the important groups of Alcyonaria, Actiniaria and Scleractinia are described.

FIG. 2.—ALCYONARIA

(A) *Clavularia,* (left) expanded polyp, (right) contracted polyp; (B) *Alcyonium,* cross section through the pharyngeal region, showing septal arrangement

ALCYONARIA

The Alcyonaria contrast sharply with the Zoantharia. Alcyonarians almost invariably construct colonies; their polyps are usually small and extremely uniform in general structure; in this they are unlike the polyps of either of the other large series of forms. Diversity among the Alcyonaria therefore affects not so much the individual as the colony; and the colonies constructed vary most extensively in form, structure and mode of development. A skeleton sufficiently resistant to retain its shape after the death of the colony is often developed; in other cases either part or the whole of the colony relies for support upon large numbers of minute calcareous bodies, which abound in its tissues and are known as spicules. Thus, the Alcyonaria include a number of creatures that produce coral. They are a group of corals that in the main inhabit coastal waters down to 550 fathoms. In general, the great depths of the sea as well as temperature and salinity limit their occurrence. Their centre of distribution is the Indo-Pacific littoral; they form an important element in coral reefs.

A typical alcyonarian polyp (fig. 2) is simpler in structure and is less variable from one genus to another than most other Anthozoa. It possesses eight, and only eight, tentacles, and these are feathered by a paired series of lateral branches on each; *i.e.,* they are pinnate. Down one angle of the flattened throat runs a groove lined by strongly ciliated epithelium. This is the siphonoglyph, and it creates a downward current of water into the coelenteron of the polyp. There are eight mesenteries, which alternate in position with the eight tentacles. Each mesentery possesses a special strip of muscle down one side; the fibres in the strip run in a longitudinal direction and are supported by ridges or lamellae of mesogloea. The whole strip of muscle is known as a retractor. By their contraction these muscles pull the upper parts of the polyp downward and inward. Each mesentery also possesses a filament, but the filaments of all the mesenteries are not alike. Those that belong to the two mesenteries farthest from the siphonoglyph are long. Each has a groove along its free edge; the groove is lined by cells with long cilia; it is Y-shaped in a transverse section. The function of these filaments is circulatory. The filaments of the other six mesenteries are shorter and consist of an epithelial cord containing many glandular cells; these filaments are digestive organs. The six last-mentioned mesenteries also contain concentrations of sex cells (gonads).

The eggs of Alcyonaria usually develop into free-swimming larvae called planulae, which in due course settle down either upon a hard support or in sand or mud, become transformed into polyps and by budding begin to construct a colony. The process of budding is peculiar, however, in that no bud is produced directly from a polyp itself; the polyps give off hollow rootlike structures that are lined by endoderm and are known as solenia, and from these the new buds arise.

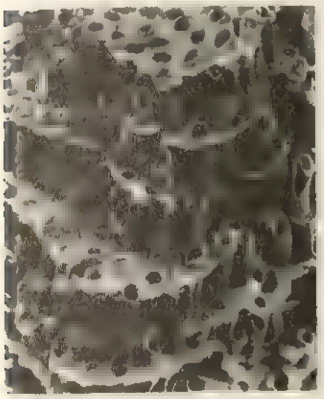
The Alcyonaria offer almost the only examples to be found among the Anthozoa of the phenomenon known as polymorphism (*see* HYDROZOA: *Polymorphism and Alternation of Generations*).

In certain alcyonarian colonies there are two kinds of polyps: the nutritive ones such as those already described and another kind known as a siphonozooid. These latter are polyps whose parts are more or less reduced, with the exception of the siphonoglyph, which is large and strongly ciliated. These individuals create water currents that circulate through the system of solenial canals penetrating the colony. In cases where a single original polyp becomes transformed into the axis of a colony this constitutes a further differentiation of individuals.

The living Alcyonaria are divided into six orders, and since the structure and mode of formation of the colonies are different in

the Gorgonacea and Pennatulacea, these are described separately from the other four orders.

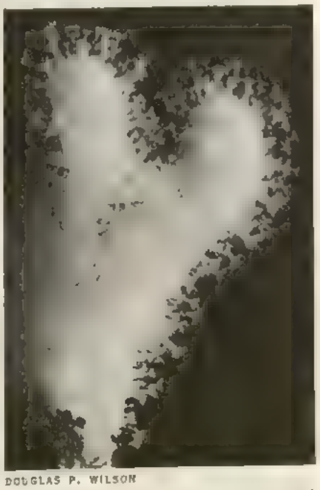
Orders Alcyonacea, Stolonifera, Telestacea and Coenothecalia.—The numerous Alcyonaria that belong to these orders possess this in common: although the colonies that they form are extremely various, there is never an axial skeleton forming a central support. A conception of the colony-forming activities of the polyps can be gained only by the study of a series of actual colonies. Fig. 3–5 will serve to illustrate the following remarks.



BY COURTESY OF THE TRUSTEES OF THE BRITISH NATURAL HISTORY MUSEUM
FIG. 3.—PORTION OF SKELETON OF ORGAN PIPE CORAL (TUBIPORA MUSICA) (ABOUT NATURAL SIZE)

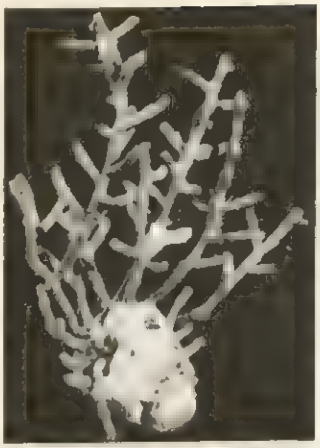
In the simplest colonies (order Stolonifera) the polyps are attached to a foreign surface and connected with one another simply by a few creeping rootlets (solenia) arising from their bases. Such a condition exists in *Cornularia.* Somewhat more elaborate are colonies such as those of certain species of *Clavularia* in which the meshes of the network of solenia have been filled up by solid mesogloea, and the network of rootlets has been converted into a continuous mat with ramifying endodermal tubes inside it and a cover of ectoderm outside it both above and below. In neither of these colonies is there any firm skeleton; the support consists simply of an external horny layer covering the rootlets and the lower parts of the polyps (*Cornularia*) or spicules (*Clavularia*).

A different grade of organization appears in certain genera whose polyps tend to grow very tall and not unduly close to one another. In such a case bridges containing solenia may grow across from one polyp to another well above the level of the bases of the polyps (*Clavularia*). This process goes a stage further in *Tubipora.* In this the polyps become inordinately long and narrow and diverge from one another as they grow up; and instead of throwing out isolated bridges across the gaps between them, they develop a series of platelike horizontal platforms that run at intervals one above the other across the colony. These platforms consist of mesogloea containing solenia and are covered externally by ectoderm. From each successive platform new polyps arise. The original polyps grow upward until a considerable number of platforms have been formed; they then stop, the polyps continuing the colony. *Tubipora,* while it is living, produces a skeleton composed of firmly compacted spicules in the mesogloea of the polyps and platforms. The tentacles of the polyps are sometimes bright green, while the skeleton is crimson; after the death of the soft parts the skeleton remains as a brightly coloured mass of tubes, often of considerable size, and is known as organ-pipe coral.



DOUGLAS P. WILSON
FIG. 4.—"DEAD MEN'S FINGERS" (ALCYONIUM DIGITATUM) (REDUCED)

Colonies of different types are formed by other genera possessing long polyps (order Alcyonacea). In *Alcyonium,* for instance, there is formed a massive colony with a small number of stout, unwieldy lobes. Each lobe consists of a number of polyps that are inordinately elongated vertically; but here, instead of producing platforms, the polyps have filled in the whole space between them with solid mesogloea so that only the head end of each polyp projects beyond the general mass. Consequently ectoderm occurs only on the exposed parts of the polyps and on the external surface of the mass connecting these; the inner parts consist of mesogloea with solenia ramifying through it and connecting the deeper parts of the polyps with each other. New polyps arise from solenia at various levels between the old ones, as the colony grows. In this instance the skeleton consists entirely of scattered spicules; these occur not only in the mesogloea of the massive portion of the colony but also in the projecting upper ends of the polyps, which are retractile into the solid part. The common British *Alcyonium* is known as "dead men's fingers" from the suggestive appearance presented by the colony when removed from the water or stranded by the tide on the undersides of overhanging rocks. Its appearance when under water with the transparent glassy polyps fully expanded is as delicate and beautiful as its retracted state is repulsive.



BY COURTESY OF FREDERICK M. BAYER
FIG. 5.—COLONY OF TELESTO SANGUINEA GROWING ON A PEBBLE. (HEIGHT OF AXIAL POLYP ABOUT 4.5 CM.)

Treelike branching colonies (order Telestacea) of other Alcyonacea may be produced in more than one way. In *Telesto,* for example, lateral polyps are budded off from solenia lying in the walls of single original polyps, which become extremely elongated (fig. 5). Since each secondary polyp grows out at an angle from its parent and itself produces further lateral polyps, it constitutes in time a branch of the main stem formed by the original polyp. A number of such branching systems may be connected with one another by basal stolons.

Lastly in *Heliopora* (order Coenothecalia), the blue coral of tropical Indo-Pacific shores, a massive blue calcareous skeleton is produced.

Order Gorgonacea.—In these animals, except in a few unusual genera that appear to be transitional between a matlike colony and a treelike one, the skeleton forms a definite axis running up the centre of a treelike colony. The soft tissues by which the axis is surrounded contain spicules.

DOUGLAS P. WILSON
FIG. 6.—PORTION OF A COLONY OF SEA FAN (EUNICELLA VERRUCOSA) (ENLARGED). POLYPS IN LOWER RIGHT CORNER ARE CONTRACTED

A typical example of the Gorgonacea is *Eunicella verrucosa,* one of the sea fans (fig. 6). This forms a treelike colony attached by a narrow base and with slender twiglike branches. Each branch has an axis of blackish horny skeleton clothed on all sides by bright pink flesh containing solenia and studded with numerous small translucent pink polyps. In certain related gorgonians the horny skeleton contains calcareous inclusions.

In *Corallium,* the well-known precious coral of commerce, the "coral" is an axial skeleton similar to that of *Gorgonia,* but in this case it is stouter and less twiglike and is formed by the fusion of innumerable spicules into a solid calcareous mass. In *Corallium rubrum* the flesh of the colony as well as the axis is scarlet, but the polyps are white.

The skeleton of the Gorgonacea, although it varies considerably in structure from one form to another, is secreted by cells of ectodermal origin that are either embedded in the mesogloea or form a distinct layer around the axis itself; this is a communal internal skeleton and does not represent an elongated axial polyp. The colony is started by a polyp that gives rise to solenia in

LENNART NILSSON
FIG. 7.—SEA PEN (PENNATULA PHOSPHOREA), LARGE SPECIMENS OF WHICH MAY ATTAIN A FOOT OR MORE IN LENGTH

the basal part of its body; from these solenia new polyps arise.

Order Pennatulacea.—The colonies included in this group are of a nature very unlike anything hitherto described and include those animals popularly known as sea pens. In a typical form (*Pennatula*, fig. 7) the colony possesses a straight central axis developed from the body of a single greatly attenuated original polyp. This axis is complicated in structure and contains a supporting rod of calcified horny material. It bears laterally arranged leaflets, each consisting of a row of close-set polyps, and is itself provided with siphonozooids. The latter occur in a number of cases among the Alcyonacea and rarely among Gorgonacea; but among Pennatulacea they are universal. Moreover, the Pennatulacea are not attached at the base to a firm support but possess a contractile lower portion that anchors the colony in sand or mud. These animals exist at extreme depths; *Umbellula leptocautis* has been taken at 4,440 m.; others have been taken at even greater depths.

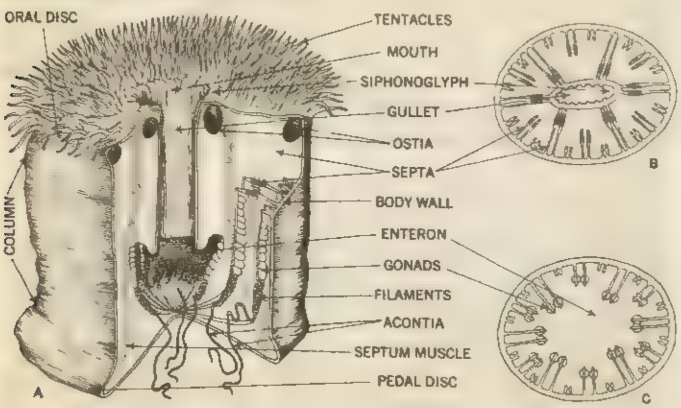
In other Pennatulids the form of the colony varies. In *Kophobelemnon*, instead of lateral leaflets the stem bears large isolated polyps; in *Virgularia* leaflets are present but reduced in size; in *Umbellula* a few large polyps occur in a rosette at the top of a long stem that is otherwise bare; in *Renilla* the basal peduncle is replaced by a flat kidney-shaped expansion bearing radially arranged polyps on its upper side.

General Note on the Skeleton.—Alcyonaria as a whole provide an extremely good example of the diversity that may exist in the skeleton within a single group. Instances have been quoted of both internal and external skeletons; of horny covering skeletons, horny axial skeletons; tubular skeletons and solid ones; skeletons formed of diffused spicules, of interlocked spicules and of fused spicules; cases in which spicules and a solid skeleton coexist, and in which horny and limy material coexist in the skeleton, not to mention the massive calcareous support of *Heliopora*. Whatever the nature of the skeleton, however, it is formed either by the ectoderm (*Cornularia*) or by cells of ectodermal origin that have penetrated the mesogloea.

ZOANTHARIA

The two important orders in this subclass are the Actiniaria and the Scleractinia (Madreporaria).

Order Actiniaria.—The sea anemones (fig. 8) constitute a large and varied group of Anthozoa that are closely related to the true corals (Scleractinia) but contrast with them in a number of ways. No sea anemone forms any skeleton; none produces a colony, so that the polyp that results from the development of an egg remains a single individual all its life except when it undergoes fission (*see* below). The polyps are of very variable dimensions, but the average order of size is relatively large, and in giant species (*Stoichactis*) an individual may exceed two feet in diameter; these are the largest anthozoan polyps in existence.

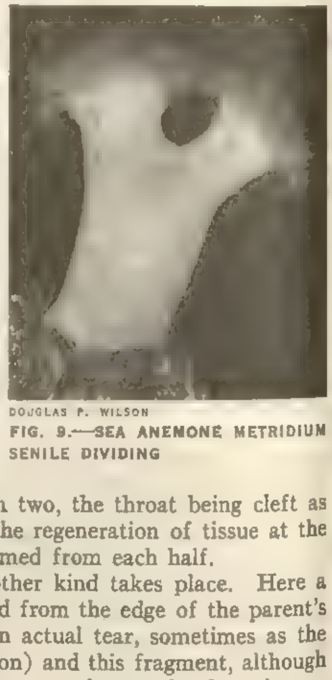


FROM R. I. USINGER & T. I. STORER, "GENERAL ZOOLOGY"; REPRINTED BY PERMISSION OF MCGRAW HILL BOOK CO., INC. (1957)
FIG. 8.—SEA ANEMONE METRIDIUM
(A) Cutaway view; cross sections (B) through gullet; (C) below gullet

An anemone is rarely completely sedentary, and, although it spends periods of varying length attached by its base to a foreign support, it can readily creep away. No other series of Coelenterata, taken as a whole, offers a parallel to this creeping habit of the anemones.

The general build of many anemones is stronger and more muscular than that of most other Anthozoan polyps; the retractor muscles of the mesenteries and the circular muscle of the body margin (sphincter) frequently attain a high degree of development. The variation in the external form of the polyp is very wide; but even greater is that of the internal organs. The number of mesenteries, their arrangement, their relation to one another with respect to size and to the degree of specialization of their musculature vary to such an extent that within limits imposed by certain fundamental principles almost any combination may be represented. No anemone possesses the characters of alcyonarian polyps, however.

The distribution of anemones is world wide. They occur at varying levels from the tidal zone to the greatest depths (10,190 m.) at which living animals have been taken in the sea. None occurs in fresh water, but a few are able to colonize brackish areas. Little is known of their geological range except that they must be of very great antiquity.



DOUGLAS P. WILSON
FIG. 9.—SEA ANEMONE METRIDIUM SENILE DIVIDING

Since sea anemones do not form colonies, the habit of budding, so prevalent in some groups of Coelenterata, is not much in evidence here. Asexual reproduction of other kinds, however, is of frequent occurrence.

In some species rapid longitudinal division (fission) of the whole anemone into two more or less equal parts is a regular habit; the animal literally tears itself in two, the throat being cleft as well as the other parts; and by the regeneration of tissue at the torn edge a new individual is formed from each half.

In other species fission of another kind takes place. Here a small fragment becomes separated from the edge of the parent's base (sometimes as a result of an actual tear, sometimes as the product of a process of constriction) and this fragment, although it contains no tentacles, peristome or throat, develops into a perfect, new anemone (fig. 9). In a few species the direction of fission is transverse.

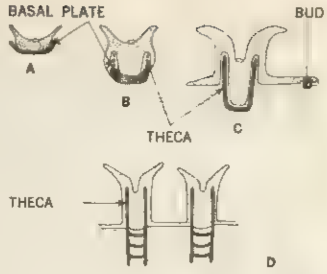
(For a classification of anemones *see* SEA ANEMONE.)

Order Scleractinia.—The Scleractinia, or Madreporaria, known zoologically as true corals, form a large group of Anthozoa characterized by their ability to secrete a limy skeleton that often is massive. The Madrepores differ from the other Coelenterata that secrete such a skeleton in that, although the size of individual polyps varies greatly, the average polyp size is large.

Moreover, the structure of the polyps is distinctive. The Scleractinia tend to form colonies containing few or many polyps; but in addition to the colonial species there is a large number of solitary forms in which a single polyp produces a single coral skeleton.

The polyps are similar to sea anemones in general build; but in their finer structure they are recognizably different. More-

over, their life is necessarily a purely sedentary one since after they have once secreted a skeleton they are permanently anchored to it, and in correlation with this and their other characteristics, they are less muscular than anemones and exhibit in particular a less marked development of the retractor muscles.



FROM THE "CAMBRIDGE NATURAL HISTORY," VOL. I, MACMILLAN & CO LTD

FIG. 10.—DEVELOPMENT OF MADREPORARIAN SKELETON

(A) Young stage of solitary coral; (B) solitary coral; (C) young stage of colonial coral; (D) zooids of advanced colonial coral

The variation of structure among coral polyps is wide; but it hardly parallels the extraordinary diversity found among the anemones. In the latter, diversity of the individual reaches its height, whereas in the colonial corals equally great diversity is reached in the relations of the polyps to one another and consequently in the form of the colony that they build up.

Corals are widely distributed in the seas of the world, and both solitary and colonial forms may occur in either shallow or deep water. The true reef-building corals, however, which are mainly colonial forms, are restricted to the tropical and subtropical zones; they flourish best in shallow water, and their depth limit is about 50 m.

The Scleractinia are an ancient group geologically, dating from Triassic times (about 200,000,000 years ago), and vast numbers of fossil forms are known. Many other corals that may or may not have been ancestral to them (the Tetracorallia, etc.) are known from much earlier times. Corals form the largest bulk of fossils belonging to the Coelenterata, and some limestones are composed almost entirely of their remains. In certain past epochs reef corals had a far wider distribution than in modern times, their remains being plentiful in latitudes at which they cannot now maintain themselves.

The skeleton of a solitary coral polyp such as *Caryophyllia* (a genus represented in Great Britain by *C. smithii,* the devonshire cup coral) is illustrated in fig. 10. It consists of a number of parts that together build up a shape definitely related to the soft parts that have secreted it. There is a basal plate attaching the whole structure to the substratum, a circular wall (theca) arising from this and a number of radially arranged vertical partitions (septa) that project inward from the inner surface of the theca toward the centre and partially subdivide its cavity. The septa are not all equal but belong to definite grades of size, which alternate regularly.

The polyp is seated in the cup of skeleton, and during life its body may extend well above and beyond the latter, overlapping also down the outside of the theca. If the polyp swallows a considerable mass of food, it must necessarily extend itself above the skeleton in order to make room in its coelenteron for the food. The tissues of its column and base form a lining in the skeletal cup, and its mesenteries alternate with the septa; the septa push the polyp's column wall inward; they nowhere penetrate into the coelenteron and are entirely external to the tissues of the animal. Thus, although there is deep interpenetration between the skeleton and the soft parts, morphologically speaking the skeleton is entirely an external structure. The skeleton is produced as a secretion of cells that are formed by the ectoderm of the base and sides of the polyp.

The eggs of corals develop into planulae that attach themselves after a time to a foreign surface, assume the form of miniature polyps and begin to build up a skeleton, which first appears between the base of the polyp and its support. Most corals are viviparous, that is, the planulae develop inside the parent polyp and are liberated as larvae. A few corals lie unattached and are anchored by the weight of their skeleton.

It must be understood that the growth of a colony is due to the continued deposition of calcareous material by the polyps, and as more and more is added the skeleton must necessarily increase in size, growing upward or outward or both. The form that any skeleton assumes is dictated by a number of factors affecting the polyps—by the way in which new polyps arise with relation to those already in existence; by their rate of formation and growth; by the relation between growth in height and growth in width; by the angle and plane of divergence between the polyps as the colony grows; by the presence or absence of a secretion of skeleton in the intervals between the polyps, and similar considerations. (For accounts of the formation of coral reefs *see* Coral Reef; also Pacific Islands: *Coral Islands.*)

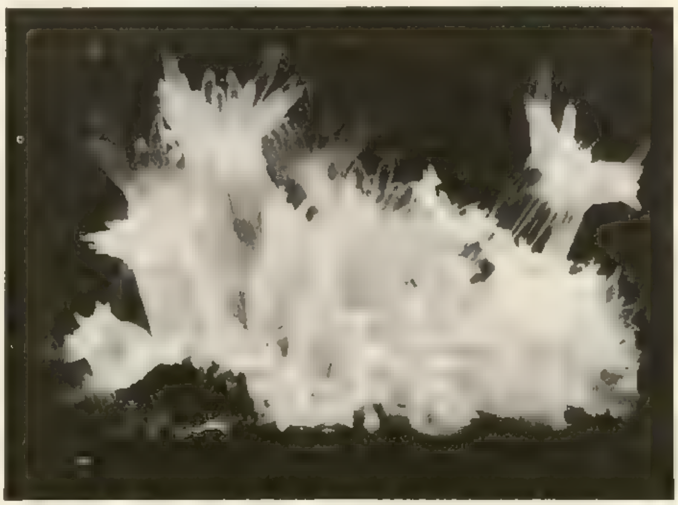
Each species of coral has inherent within its polyps the ability to develop in a given manner, and the form of the colony is also affected by the degree of its exposure to wave action. Something is known about the details of colony formation from actual observation and measurements of the growth rate. The older accounts concerning the processes by which the polyps increase in number should be read with reserve, since the ideas in vogue on this subject have until recently been largely speculative, and theories of colony formation have been too frequently based on the study of the skeleton. It is obvious that the skeleton is an imperfect even though permanent record of the activities of the polyps; studies of polyps reveal that in some cases conclusions as to the manner of growth may be entirely erroneous if based on the skeleton.

A study by G. Matthai of the soft parts of a number of corals from which the calcareous matter has been dissolved away leads to the conclusion that in the cases investigated (and probably in the group in general) polyps are formed in two ways. This has since been confirmed by direct observation.

Intratentacular Budding.—By intratentacular budding a polyp becomes compound. It has originally one mouth and throat surrounded by a peristome and a circlet of tentacles, and within the ring of tentacles, at given points on the peristome, one or more new mouths and throats arise. The form of a polyp with two or more mouths will become modified, and this process may reach an extraordinary degree of development, ending up in one or several branching polyps each with a number of mouths arranged in a row. The result is a colony of the type illustrated in fig. 11.

The skeleton in such a case consists of a series of winding ridges alternating with valleys containing septa, and is known as a meandriform coral. In other colonies formed by intratentacular budding, portions of the growing polyps, each containing a newly formed mouth, become separated from the rest of the polyp as growth proceeds; but this process is to be distinguished from true fission, which involves the cleavage of a polyp through its original mouth and throat and not the gradual separation of a portion of its tissues associated with a newly developed throat.

Extratentacular Budding.—By this method a new polyp is formed from tissues lying entirely outside the circlet of tentacles of any pre-existing polyp. The polyps in such colonies each have



BY COURTESY OF THE AMERICAN MUSEUM OF NATURAL HISTORY

FIG. 11.—YOUNG COLONY OF STAR CORAL (ASTRANGIA DANAE). EACH POLYP MAY REACH A HEIGHT OF ABOUT ONE-HALF AN INCH

one mouth and are therefore relatively easily recognized as entities. Extratentacular budding sometimes take place at the periphery of colonies in which intratentacular budding is characteristic; in colonies formed by extratentacular budding, polyps with two throats may occasionally arise by the opposite method.

The classification of Scleractinia is a vexed question. The vital parts of the organisms are the polyps, and as yet too little is known of the structure and the potentialities of these throughout the group to make possible the construction of a satisfactory system.

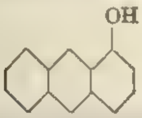
ANTHRACENE, a hydrocarbon obtained from the fraction of the coal-tar distillate boiling between 270° C. and 400° C. (from the Greek *anthrax*, "coal"). This high-boiling fraction is allowed to stand for some days, whereupon it partially solidifies. It is then separated in a centrifuge, the more fusible impurities are removed by means of hot water, and the residue is finally hot-pressed.

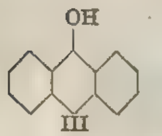
The crude anthracene cake is purified by treatment with the higher pyridine bases, the operation being carried out in large steam-jacketed boilers. The whole mass dissolves on heating, and the anthracene crystallizes out on cooling. The crystallized anthracene is then removed by a centrifugal separator and the process of solution in the pyridine bases is repeated. Finally the anthracene is purified by sublimation.

Many synthetic processes for preparation of anthracene and its derivatives are known. It is formed by the condensation of acetylene tetrabromide with benzene in the presence of aluminum chloride and similarly from methylene dibromide and benzene, and also when benzyl chloride is heated with aluminum chloride to 200° C. Anthracene ($C_{14}H_{10}$) crystallizes in colourless monoclinic tables which show a fine blue fluorescence. It melts at 213° C. and boils at 351° C. It is insoluble in water, sparingly soluble in alcohol and ether, but readily soluble in hot benzene. It unites with picric acid to form a picrate, $C_{14}H_{10}.C_6H_2(NO_2)_3.OH$, which crystallizes in needles, melting at 138° C. Anthracene and some of its derivatives are used in scintillation counters for the detection and measurement of ionizing radiation. (*See* NUCLEAR INSTRUMENTS: *Scintillation Counters.*)

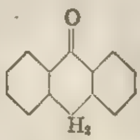


I

II



III



IV

The α- and β-hydroxyanthracenes (anthrols) with structures I and II, respectively, resemble the phenols. On the other hand, 9-hydroxyanthracene III reverts spontaneously to the ketonic anthrone form IV, from which it is made by the action of first a strong base and then an acid. Anthrone itself is made by the reduction of anthraquinone (*q.v.*).

Oxidizing agents convert anthracene into anthraquinone; the production of this substance by oxidizing anthracene in glacial acetic acid solution with chromic acid is the usual method employed for the estimation of anthracene.

ANTHRACITE: *see* COAL AND COAL MINING.

ANTHRAQUINONE, a paraquinone, is the most important derivative of anthracene. It was first prepared in 1834 by Auguste Laurent.

The most important physical property of anthraquinone ($C_{14}H_8O_2$) is that it is coloured, although but lightly so. It is in itself a chromophore. By the addition of groups such as hydroxy, amino, or substituted amino the colour of the substance is deepened to such an extent that derivatives can be made which cover every shade of the spectrum. The following table illustrates this property:

Substance		*Colour*
1 hydroxy	anthraquinone	lemon yellow
1 amino	"	reddish orange
1 methylamino	"	bluish red
1,2-dihydroxy	" (alizarin)	deep yellow
1,4-dihydroxy	"	red
1,4-diamino	"	violet
1,4-dimethylamino	"	blue
1,4-di-para-toluido	"	green
1,4,5,8-tetraamino	"	deep blue

Anthraquinone can be made by the oxidation of anthracene or by synthesis from phthalic anhydride (*q.v.*). Commercially it is made by both methods in most of the countries of Europe, Britain included; in the U.S., however, it is made by synthesis only.

Anthraquinone first became commercially important about 1870. In 1868 Karl Graebe and Karl Liebermann had established the chemical constitution of alizarin (*q.v.*), the base for very important dyestuffs and pigments, and had made it from 1,2-dibromoanthraquinone. Then in 1869 these investigators in Germany and W. H. Perkin in England simultaneously developed a commercially feasible process for making alizarin from sodium anthraquinone-2-sulfonate. With anthraquinone available commercially, much work was done on its derivatives. Within the next 30 years a whole line of dyestuffs, mostly for wool, was made from it. Then in 1901, R. Bohn discovered the first vat dyestuff derived from anthraquinone by fusing 2-aminoanthraquinone in molten caustic potash. The product, intensely blue in colour, was called indanthrene. It proved to be N,N′-dihydro-1.2:2′:1′-anthraquinoneazine. Chemically, this was a development of the first order, for over the next half century vat dyestuffs derived from anthraquinone became the most important class of the synthetic colouring matters. Like many other vat dyes, the anthraquinone derivatives are characterized by great fastness.

Several substituted anthraquinones, the 2-chloro and the 2-methyl, are also used for the manufacture of vat dyestuffs. They are prepared commercially by substituting chlorobenzene and toluene respectively for benzene in the above synthesis.

Anthraquinone crystallizes in yellow prisms, sublimes in yellow needles and melts in the neighbourhood of 285° C. It is extremely stable toward further oxidation but may be easily reduced under either acid or alkaline conditions to form a variety of products. One of the most important chemical properties of the substance is its ready reduction in alkaline solutions by means of sodium hydrosulfite, $Na_2S_2O_4$, to anthrahydroquinone, the alkali metal salts of which are soluble in water. With the derivatives of anthraquinone, corresponding reactions are used in the dyeing process. Another important chemical property is that it is readily sulfonated, nitrated and halogenated. (J. H. Ss.)

ANTHRAX (SPLENIC FEVER, MALIGNANT PUSTULE, WOOL-SORTERS' DISEASE; French *charbon*, German *Milzbrand*) is an acute, specific, infectious, febrile disease of animals including man caused by *Bacillus anthracis*, an organism which under certain conditions forms highly resistant spores that may persist and retain their virulence in contaminated soil or other material for many years. Primarily a disease of animals, chiefly Herbivora, the infection may be acquired by persons handling wool, hair, hides, bones or the carcasses of affected animals.

History.—Anthrax is one of the oldest recorded diseases of animals; it is mentioned by Moses in Ex. ix, 9, and by Homer, Hippocrates, Ovid, Galen and Pliny. Virgil in his *Georgics* describes it in epizootic form. Devastating epizootics of the disease are recorded by many medieval and modern writers.

In the 18th and 19th centuries it sometimes spread like a plague over the southern part of Europe, taking a heavy toll of human and animal life. Anthrax was the first disease of man and animals

in which the causative agent was definitely demonstrated as a specific microorganism—by C. J. Davaine in 1863, and in 1876 by Robert Koch, who isolated the organism in pure culture. It was also the first infectious disease against which a bacterial vaccine was found to be effective, by Louis Pasteur in 1881. These discoveries led to the origin and development of the modern sciences of bacteriology and immunology.

Anthrax occurs throughout the world. Repeated epizootics of the disease resulted in heavy contamination of the soil, especially in southern Europe and parts of Asia, Africa and North and South America. Districts of periodic contagion exist in Arabia, Argentina, Australia, Brazil, Chile, China, Egypt, France, Greece, India, Iran, Italy, Japan, Mexico, Morocco, Poland, Thailand, the U.S.S.R. (including Siberia), the United States and Uruguay.

The Disease in Animals.—Practically all animals are susceptible to anthrax.

Cattle, sheep, goats, horses and mules, the most commonly affected, usually acquire the disease by grazing on contaminated pastures. Outbreaks in swine, dogs, cats and wild animals held in captivity generally result from consumption of contaminated food.

The disease may occur in a peracute, acute, subacute form (internal anthrax) or in a chronic or localized form (external anthrax). The peracute form, most common in cattle, sheep and goats, occurs at the beginning of an outbreak and is characterized by its sudden onset and rapidly fatal course. Victims may show trembling, difficult breathing and convulsions but are frequently found dead without showing premonitory symptoms. In the acute and subacute forms, most common in cattle, horses and sheep, there is excitement and a rise in body temperature followed by depression, spasms, respiratory or cardiac distress, trembling, staggering, convulsions and death. Bloody discharges sometimes emanate from the natural body openings, and edematous swellings may appear on different parts of the body. During the course of the disease pregnant animals may abort, rumination ceases and the milk secretion is reduced. Horses show severe colic, fever, chills, a bloody diarrhea and swellings in the region of the neck, lower abdomen and external genitals.

The acute form usually terminates in death within a day or two; the subacute form may lead to death in three to five days or longer, or to complete recovery after several days.

Chronic anthrax occurs mostly in swine and dogs and is characterized by marked swelling of the throat, difficult breathing and a blood-stained frothy discharge from the mouth. Affected animals sometimes die of suffocation. Carcasses of animals dead of anthrax present a general picture of septicemia. There is usually rapid bloating and decomposition, dark-coloured blood that fails to clot rapidly, incomplete *rigor mortis*, oozing of blood from nostrils and anus, and a greatly enlarged spleen.

Prophylactic vaccination is extensively used in preventing anthrax in livestock. Excellent results are obtained when affected animals are treated in early stages with specific antiserum or penicillin. During outbreaks strict quarantine measures, proper disposition of diseased carcasses, fly control and good sanitation are essential in controlling the disease.

Anthrax in Man.—Anthrax in humans occurs as a cutaneous, pulmonary or intestinal infection; the most common type occurs as a primary localized infection of the skin in the form of a carbuncle. It usually results from handling infected material, lesions occurring mostly on the hands, arms or neck as a small pimple which develops rapidly into a large vesicle with black necrotic centre (the malignant pustule). Should this condition become generalized a fatal septicemia may ensue.

The pulmonary form ("woolsorters' disease") affects principally the lungs and pleura and results from inhaling anthrax spores where hair and wool are processed. This form of the disease usually runs a rapid course and terminates fatally. The intestinal form of the disease which sometimes follows the consumption of contaminated meat is characterized by an acute inflammation of the intestinal tract, vomiting and severe diarrhea. Anthrax is occasionally transmitted to man by spore-contaminated shaving brushes or by wearing apparel such as furs and leather goods.

The nearest approach to a human epidemic of anthrax during the 20th century occurred during World War I when large numbers of British and U.S. troops and many persons in the civilian population of England and the United States were infected by the use of shaving brushes imported from Japan.

Prompt diagnosis and early treatment are of great importance. Antianthrax serum, arsenicals and antibiotics such as penicillin, aureomycin, chloromycetin and terramycin are used with excellent results. The treatment of choice is penicillin or neoarsphenamine. The hazard of infection to industrial workers can be reduced by sterilization of potentially contaminated material before handling, protective clothing, use of respirators and good sanitary facilities, and in agricultural workers by avoiding the skinning or opening of animals dead of the disease.

ANTHROPOID APE: *see* APE.

ANTHROPOLOGY (ARTICLES ON). Anthropologists study human beings. In the 1960s, more than ever before, they were sharing in a search for systematic understanding of human nature (*q.v.*) with fellow scientists from other disciplines as well as with philosophers and theologians (*see* ETHICS, COMPARATIVE). The interests of anthropologists, as described in ANTHROPOLOGY, spill over into a wide spectrum of specialties in the physical, biological, behavioural, and social sciences.

Anthropologists have made considerable use of information provided by archaeologists in their attempt to understand the origins of modern customs, art, and social and political life. Atomic physics has contributed such techniques as radiocarbon dating for estimating the relative ages of archaeological finds. Efforts to establish the geographic origins of the different peoples have been supported with methods developed by biological scientists, particularly those concerned with the study of human heredity. In applying the techniques of genetics to the inheritance of blood types, for example, it has been possible to verify the conclusion that European gypsies originally came from India. Psychological principles, especially those from psychoanalytic theory, have been employed by anthropologists in an effort to understand family relationships, prohibitions against incest, and religious and legal practices among different peoples. Discussions of topics closely involved in modern anthropological practice may be found in such articles as ARCHAEOLOGY; RADIOCARBON DATING; PSYCHOANALYSIS; PSYCHOLOGY; SOCIOLOGY; and GENETICS, HUMAN.

Thus far, anthropologists have made their most distinctive contributions to an understanding of people as biological organisms (as studied in physical anthropology) that generate unique cultures (covered in cultural anthropology). Efforts in physical anthropology are summarized in RACES OF MANKIND; MAN, EVOLUTION OF; NEGRO; MONGOLOID; CAUCASOID; ANTHROPOMETRY; HAIR; BLOOD GROUPS; and SKULL: *The Skull in Anthropology*.

However, anthropology has contributed most heavily to an understanding of human cultures; much of this work is presented in overview as SOCIAL ANTHROPOLOGY; and CIVILIZATION AND CULTURE. Since most professionally trained anthropologists come from technologically sophisticated societies, they have tended to concentrate on lesser-known cultures of more primitive technology. Material aspects of such societies are discussed in DWELLINGS, PRIMITIVE; AGRICULTURE, PRIMITIVE; HUNTING AND FISHING, PRIMITIVE; ECONOMIC ANTHROPOLOGY; MATERIAL CULTURE; WEAPONS, PRIMITIVE; TRADE, PRIMITIVE; CURRENCY, PRIMITIVE; and are considered in such articles as TRANSPORTATION; MUSIC, PRIMITIVE; MUSICAL INSTRUMENTS; PRIMITIVE ART; WOOD CARVING; BARK CLOTH; and MATERIAL CULTURE.

Cultural variations involving family and group relationships receive attention in KINSHIP; KINSHIP TERMINOLOGY; DESCENT, SYSTEMS OF; CLAN; MATRILINY; MARRIAGE, PRIMITIVE; EXCHANGE MARRIAGE; COUSIN MARRIAGE; POLYGYNY; POLYANDRY; and DUAL ORGANIZATION, while additional questions of social and legal status are covered in such articles as CASTE (INDIAN); LAW, PRIMITIVE; COMMUNISM, PRIMITIVE; LAND TENURE, PRIMITIVE; and AGE SET. The reader who seeks to learn of unusual practices and beliefs in many cultures may be attracted to HEAD-HUNTING; MUTILATIONS AND DEFORMATIONS; INFANTICIDE; CANNIBALISM;

SCALPING; ORDEAL; SACRIFICE; SUPERSTITION; RELIGION, PRIMITIVE; MAGIC, PRIMITIVE; TOTEMISM; TABU; ANIMAL WORSHIP; ANIMISM; LYCANTHROPY; METEMPSYCHOSIS; SECRET SOCIETIES, PRIMITIVE; PEYOTISM; FUNERARY RITES AND CUSTOMS; MANA; LIGHTNING; DANCE, PRIMITIVE; MYTHOLOGY, PRIMITIVE; FOLKLORE (AMERICAN INDIAN); TATTOOING; RITES AND CEREMONIES; CIRCUMCISION; and TREE BURIAL.

The raw materials on which the generalizations of anthropology are based come from empirical study of many specific cultures. *Encyclopædia Britannica* abounds in reports of the history and modern status of these groups of people, including INDIAN, NORTH AMERICAN; INDIAN, LATIN-AMERICAN; ESKIMO; IROQUOIS; NAVAHO; ARAB; AUSTRALIAN ABORIGINES; AINU; BASQUE; BERBER; GYPSY; MALAY; MONGOL; and PAPUAN. The Index supplies references to many more. In addition, the anthropology of particular geographic areas is discussed under such titles as OCEANIA; MELANESIA; MICRONESIA; POLYNESIA; CAUCASUS, PEOPLES OF; as well as in articles dealing with the continents (AFRICA and ASIA, for example) and with more limited geographic or political units (NEW GUINEA or JAPAN, for example).

Clearly, the concerns of anthropology range widely, and are faithfully reflected in these volumes from ABIPÓN to ZUTUHIL, and from ACCULTURATION to ZUÑI.

ANTHROPOLOGY. Anthropology, in its development and branches, can be characterized as the naturalistic description and interpretation of the diverse features of mankind. Its approach to the manifold variations among peoples is at once universal and comparative. It cannot be effectively defined in terms of an exclusive subject matter or a single method of study. It differs from history, as commonly understood, not by excluding historical studies of peoples, institutions, beliefs or customs, but by using as far as possible direct observation of human beings, their activities and their products rather than documentary accounts; and also by viewing the results of any such study as part of the total human record and as a contribution to the better understanding of the complex processes involved in the biological and cultural development of man. Similarly, it differs in approach from physiology or psychology in concerning itself with variations and collective differences in human physique and mentality. Thus, anthropologists seek to study and interpret the special characteristics of any particular population or activity in terms of its time and place in the total history of mankind; but any claim that anthropology encompassed the study of man in its entirety including research and description concerning all human characteristics and activities would, of course, be both presumptuous and futile.

The present article is divided into the following sections:

I. GENERAL SURVEY

1. Historical Background.—It was through attempts to describe and explain physical types, customs, beliefs and forms of social organization that lay outside the more familiar world of earlier western knowledge and yet were held to be ultimately related to it that anthropology developed its generalizing tendency and its assumption that any particular people was, whether in physique or custom, to be viewed as a variation on a common human theme and to be described and explained in terms of characters and processes relevant to all mankind. This conception was developed in the 19th century, in an effort to integrate knowledge of all periods of human history and from all relevant branches of science. It was especially stimulated by the impact of the doctrine of biological evolution on ideas concerning human progress already developed by philosophers in the 18th century. The greatly lengthened perspective of the age of the earth and of the antiquity of mankind, which was opened up by the 19th-century geologists and naturalists, gave a new importance to speculations on cultural and social development, while the successes of 19th-century technology in bringing the whole world into view also encouraged attempts at reformulating man's place in nature. The variety of behaviour and belief among the many peoples of the world, on which travelers and scholars had been reporting and speculating since the Age of Discovery, challenged inquiry into both the causes of such diversity and the manifold connections between various aspects of human life.

The philosophers of the Enlightenment, both on the continent and in England, had sought to formulate general schemes of social and cultural advance whereby, as Hume expressed it, there had been a gradual "improvement of human society from rude beginnings to a state of greater perfection" through successive stages, later schematized by Lewis H. Morgan as savagery, barbarism and civilization. The great explanatory value of the evolutionary principle with regard to the complexity and diversity of organic life lent strong support to concepts whereby the diversity of human cultures in such fields as economy, government and religion could be interpreted in terms of progressive developments from simpler forms. The weight of Christian cosmology had been inimical to the general acceptance of these ideas until the geologists and naturalists undermined the dogmatic authority of the biblical story of creation. But the way was then opened for more objective study and comparison of the peoples of the world both past and present. The recognition in the late 19th century of an increasing number of fossil remains as those of human beings differing markedly from any living peoples demonstrated the great antiquity of "diluvial" man. Charles Darwin's hypothesis of natural selection as a mechanism of organic change heightened scientific interest in the relations between biological and cultural conditions and there was much early speculation as to the effects of environment on physical and cultural types and of biological factors on technical and social advances.

Herbert Spencer viewed the high level of organic complexity reached in man in the course of biological evolution as the foundation of what he called superorganic development. This he regarded as molded in part by the primary factors of biological inheritance and of the physical environment, but also by secondary factors which emerged in the social process itself, such as the tendency of society to increase in size and density; the internal reciprocal action of groups within any society; the action and reaction be-

tween societies; and finally the accumulation of "superorganic products," such as language, knowledge, morals and aesthetics, or what anthropologists would now call culture.

Stressing the importance of elucidating all the factors determining the qualities of a particular people or form of society, he emphasized the significance of comparative methods and of studying the widest range of peoples in seeking to understand the genesis and *raison d'être* of customs and institutions, paying special attention to primitive societies which were small in scale so that the totality of their way of life could more readily be grasped and analyzed.

Spencer's interests were essentially sociological, and while he recognized that social processes and systems could only be perceived and formulated by abstraction from actual manners and customs, he did not focus attention on the needs and difficulties of their objective and systematic examination. It was Sir Edward Burnett Tylor who, following Otto Klemm, provided the modern anthropological connotation of the term culture, opening his famous book, *Primitive Culture* (1871), with a descriptive definition of culture as "that complex whole which includes knowledge, belief, art, law, morals, custom and any other capabilities and habits acquired by man as a member of society." For Tylor the content of culture, its organization and variability were of direct and intrinsic interest. He placed greater stress than Spencer on the complexity of the long historical processes of cultural change, and also on the effects of specific environmental conditions, migrations and contacts in stimulating particular developments, and thus of the need for their detailed study. His empiricism and his interest in the character and determinants of cultural forms justify his title as the father of modern cultural anthropology. He accordingly stressed the need to tread the slow road of detailed ethnographic inquiry and of meticulous comparison of attendant circumstances before proceeding to the more abstract levels involved in generalizing about society and its evolution.

The close association of biological, cultural and sociological interests in the development of anthropology followed from the belief that human life as a whole was the complex result of a series of interconnected fields of development. Since their views were evolutionary, the early anthropologists were as interested in paleontological evidence concerning the physique of extinct peoples, and archaeological evidence concerning extinct cultures, as in racial variations and cultural differences among living peoples. All were recognized as contributing to the general interpretation of human development and activity. The primitive and ancient, then as now, were not emphasized exclusively or for their own sake, but because of the contribution that the study of early man and of the simpler living societies could make to a general understanding of man's place in nature.

However, the wide range of problems that emerged required investigation of different kinds of evidence by a variety of methods. It accordingly stimulated inquiry in many areas of knowledge that were developing during the later part of the 19th century and fostered the exchange of information and ideas among workers in diverse fields. Comparative anatomists, geologists and archaeologists began to co-operate in the study of early man as revealed in fossil remains and the stone tools of the Ice Age. Ethnographers recording the ways of life of living primitive peoples co-operated with ancient historians, folklorists and philologists in the study of early customs and social institutions. Inevitably, too, as knowledge further increased, still greater specialization developed. The elaboration of new methods and the growing body of material encouraged concentration in limited fields and on specific problems, so that anthropological research itself divided into a number of specialties. There was an early divergence between those concerned with the biological and with the sociocultural aspects of human development, which led to the recognition of the distinct branches of physical and cultural (or social) anthropology. In continental Europe this has long been recognized by restricting the term "anthropologie" to physical anthropology and by using the term "ethnologie" for cultural studies. Within these branches further distinctions have developed. In the former the study of the biological evolution of man has been advanced by paleontological and anatomical researches as an integral part of the study of the primates, the mammalian order to which man belongs, while the analysis and interpretation of the variations in physique among the peoples of the world have depended mainly for their advance on the application of statistical methods and later of genetical theory. In the sociocultural field, interests have also tended to divide according to whether the main concern has been, on the one hand, with the sequences of cultural development in particular regions or, on the other hand, in the elucidation of underlying processes involved in certain general aspects of human culture and social organization. These have given rise, respectively, to specialized researches in ethnology and into the functioning of cultures and social systems. The widely varying nature of the material available for study has again led to further specialization in methods. By increasingly systematic excavation of prehistoric sites and the comparative study of relics and their contexts it has been possible in the few regions that have been intensively studied by archaeological methods to recover at least in outline a continuous record of the cultures of the peoples that succeeded one another from the Stone Age down to the present. The prehistorians have increasingly specialized on particular periods or geographical areas, and their problems and techniques have differed according to whether they dealt with relic-bearing caves, beaches and peat bogs, with the dwelling sites and graves of primitive cultivators or with the deep deposits and elaborate constructions preserved in ruined prehistoric cities. In regions beyond the range of modern archaeological knowledge, notably over much of Africa, Australasia, Oceania and the new world, attempts have been made to reconstruct cultural sequences by comparative studies of the ethnography of their living peoples. Tentative as the results have often been, they have afforded valuable guides for the planning of later ethnographic and archaeological research.

Thus anthropology as a subject of study in English-speaking universities generally includes teaching and research in both the physical (biological) and the sociocultural fields, and in both of these there have been further specializations of approach. In physical anthropology, continuing discovery and examination of fossil remains provides material for the systematic morphological study of human evolution (human paleontology and primatology). Investigations of living populations are directed to defining and interpreting their variation; *i.e.*, to the study both of the gross differences in the predominant characters between populations from different major regions of the world (*e.g.*, Mongols of eastern Asia as compared with African Negroes) and of the variability of physical characteristics within a given population. Within this branch of the physical anthropology of living peoples, in addition to the earlier developed morphological and statistical studies, new studies in physiological variation and genetic analysis of variability are being developed.

In cultural and social anthropology, also, there are several perhaps less sharply defined specializations, not all of which are everywhere included in general teaching or equally emphasized, and some of which may be pursued in association with other disciplines such as psychology and sociology. The need remains for a broad presentation in general ethnography and culture history of the varieties, long-term development and processes of diversification of human cultures as well as for an evaluation of the influence of the many underlying factors. But intensive study can no longer embrace the broader phases of development, and simple schemes of cultural evolution are no longer of heuristic value.

Prehistoric archaeology, in the discovery and the analysis of surviving relics of extinct cultures and their environment, has become a highly specialized discipline of field excavation and laboratory study, the techniques of which vary according to the nature of the sites and the character of the cultural and other remains. In some regions, such as Europe, the intensity of research, the wealth and complexity of the material and the growing precision of chronological studies have required further specialization on particular phases; *e.g.*, the Paleolithic. In other parts of the world, notably North America, much archaeological research is concerned, in its later chronological phases, with the immediate ancestors of the living aboriginal populations available for study. Thus, for

example, in California or in the southwest of the United States there can be a direct continuity and community of interest between archaeological and ethnographical research in the study of the ethnology of particular peoples or areas.

Ethnography carried out by field research among an existing population provides the essential data for various more specialized sociocultural studies, whether topical or comparative. The study of general ethnography, which surveys the primitive world descriptively, and of ethnographic monographs, provides, as already mentioned, an essential background for appreciating the variations and problems which have given rise to different approaches in specialized studies. Within ethnography there is the specialized but basic field of primitive technology, in which the development, context and significance of crafts and art are studied. The term "ethnology" is now generally applied to studies chiefly concerned with the historical reconstruction of the cultural development of particular peoples or regions.

Social anthropology concentrates on the analysis and explanation of the whole range of social relations as parts of a system of social organization or social structure. It is concerned with the function of institutions, both in relation to the social system as a whole and as contributing to human needs. Both social organization and particular social institutions are analyzed, according to their relevance, with reference to the various fields, *e.g.*, political, legal and economic, of human interest and interaction. Religious beliefs and ritual are considered within this framework, especially for their significance in maintaining and sanctioning social norms.

A further specialization in the collection and study of ethnographic data which has become a main focus of interest for some American anthropologists is to be found in what are variously known as "configurational" or "culture and personality" studies. These are concerned with the analysis of differing basic values and underlying assumptions in the view of life of various cultures and their expression in the personalities of those who share in them. Such studies seek on the one hand to discover and portray the measure of unity and coherence in thought and judgment which provides the common understandings of a cultural group. They also often apply psychological principles and hypotheses of personality development to the explanation of the genesis and persistence of particular patterns and values.

Linguistics also has been considerably developed within the framework of anthropological studies. The recording and systematic analysis and comparison from several points of view of the innumerable speech forms of peoples outside the historic civilizations have been undertaken largely by anthropologists specializing in linguistics. Their attention is directed not only to the philological or genetic study of the historical development of particular languages, but often to the detailed analysis of the phonetic and grammatical structure of a language considered as a system of sound signals governed by implicit principles which maintain its unity and the direction of its changes. Languages are also studied and presented semantically as systems of meanings which deeply affect modes of thought and behaviour, and can thus provide an important key to the study of cultural values.

2. Evolution and Racial Variation in Man.—Physical anthropology (*see* below) is concerned with the related problems of tracing the emergence of man as an animal form and the nature, causes and significance of past and present variations in the biological characters of the various human species and breeds. Much research continues to be directed to the study of primate, and in particular, human, variation in time and space and to the determination of the mechanisms which have brought it about. But the focus of interest, in harmony with a trend throughout much of biology, has tended to shift from morphological comparisons to considerations of function. An outstanding feature of the primate order is the high development of the central nervous system, and especially of the brain. The importance for the emergence of man of a number of evolutionary changes in the organization of the primate brain has long been recognized, but a simple concept of increasing morphological complexity from lemurs, monkeys and apes culminating in man, accompanied by a corresponding change in mental complexity, does not do justice to the facts. It may be conjectured that physiological work, using electrical and other methods, on the functioning of the brain will eventually allow a reinterpretation of primate cerebral evolution on a more exact and critical foundation. Although some other physiological work, particularly on the primate sexual cycle, has been done, and there is a growing body of laboratory and field studies on primate behaviour, much remains to be done before a comprehensive view can be gained. There is also a tendency, again reflecting general trends in the biological sciences, to attempt a more quantitative treatment of anatomical problems. Very useful metrical work has, for example, been done on the varying bodily proportions of primates, so that the range of variation within a species can be appreciated and so that comparisons obtained by statistical methods càn replace subjective impressions.

The study of fossil remains of man and other primates is dependent for its advances on the discovery of new material, which is often as much a matter of chance as of planned research. Human fossils have always excited public interest and often, unfortunately, an unreasonable partisanship in scientific circles. The fragmentary character and rarity of most kinds of primate fossils have tended to encourage wild speculation and premature judgments on the basis of a small amount of evidence. Since 1930, however, finds have been made which are very important because of the number of individuals of the species represented and because the parts of the skeleton are more complete and extensive than those available before. A remarkable abundance of finds in south Africa of a fossil species or group of species of apelike form known as the Australopithecinae has renewed interest in an earlier stage of human evolution. Although many features of the skull, including the small brain, appear to be closer to the range in apes rather than in man, there is strong evidence that these creatures, which were not arboreal forest dwellers, may have been capable of erect locomotion. It may be remarked in this connection that, as intermediate forms become known in increasing numbers, the decision as to what is to be regarded as human will become arbitrary, depending on the criteria adopted. Fortunately, the controversies concerning the interpretation of these remains have every prospect of being cleared up by the discovery of more material. Meanwhile, the earlier history of the anthropoid apes has also been illuminated by rich discoveries of Miocene Age in Kenya. Previously, fossil anthropoid remains have been very rare and fragmentary and the newer finds tend to indicate a more complex variety of early forms than was previously envisaged, and that these early apes lacked the specialization of structure connected with arm-swinging arboreal locomotion, which characterizes modern anthropoids.

As Europeans after the Age of Discovery became better acquainted with the peoples of many outlying parts of the world, naturalists began to make classifications of human types. For this purpose J. F. Blumenbach at the end of the 18th century developed a method that included cranial measurement and constructed a five-fold division of mankind into white, yellow, black, Malayan and Amerindian races to correspond with what was then known about predominant differences in physical appearances of the peoplés of the several great regions of the world. Since measurement had great prestige and evolutionary theories in biology had not yet developed, anthropology inherited from this pioneer work an oversimple theory of racial divisions which assumed a fixity of separately created species. For the broad classification of mankind into a few types based on selected combinations of skin colour, hair form and head shape does not necessarily correspond to any over-all genetic unity within, or division between, the so-called "races" that are thus defined.

The modern study of living population has been increasingly influenced by Mendelian genetics, much advanced in scope and subtlety. For the purpose of tracing ancestral relationships it is the demonstrably inherited features of the organism which count. Variations within or between human populations may, in large measure, be determined by genetic contribution but they may also be the results of differences in conditions of life. A bald division into genetic and environmental factors is, it must also be remembered, an oversimplification, since the action of genes may itself be modified by environmental conditions, and one sometimes has to

deal with complex interactions between the two. Nevertheless, some features such as the human blood groups appear to be very little, if at all, affected by change in environment, while others, such as stature or, still more, intelligence, appear to be susceptible to extensive modification by environmental factors such as nutrition in the former instance and education and other cultural factors in the latter. It is generally accepted that the ultimate source of biological variation is gene mutation. By the processes of Mendelian inheritance a great variety of gene combinations can thus become available to be acted upon by natural selection. The work of genetical statisticians has provided a powerful theoretical background for evolutionary study by indicating the rate at which evolutionary change may be expected to occur under given particular mutation and selection rates.

The existence of physical differences between populations of different geographical areas and between individuals within any given population is an obvious fact. One task of physical anthropology has been to give an objective and thorough description of these differences as a preliminary step in determining how they have come about. Populations are never homogeneous with respect to a particular characteristic, and the variations in, for example, body measurements or skin pigmentation within any population are continuous; *i.e.*, given individuals may have any measure or degree of pigmentation within a certain range. The essentially statistical character of population differences is thus evident. The variability within populations and the gradual character of geographical differences being what they are, the distortion involved in attempting to classify mankind into sharply distinguished and mutually exclusive groups is apparent. At the same time, the substantially continuous predominance over wide geographical areas of particular combinations of skeletal, skin and hair features, such as characterize the Mongoloid, African Negroid and Caucasoid (white) populations in the old world, does suggest that there was an early differentiation of *Homo sapiens* into a number of populations each having some particular and stable combinations of characters, and that some of these came to predominate in different regions, affording a basis for the division of mankind into the "great races" of the earlier anthropologists.

An observed physical character is the end product of the activity of a few or of many genes. Even if the end result is not modified by environmental factors, it may still not give a precise clue to the genetic constitution. Characters which look alike by all available means of observation may not have the same genetic basis and may therefore be misleading in evolutionary studies. It seems that populations are seldom distinguished by the unique possession or complete absence of particular genes, though frequency differences may be large. For example, the curious inherited anomaly of the red blood cells known as sickle-cell trait, which has a frequency of 25% or more in some African tribes, has an incidence of only one in many thousands in western Europe.

These facts emphasize the essential biological unity of the human species. The notion of "pure races" is seen to be fallacious and classification into sharp categories cannot be achieved without doing violence to the statistical nature of the observed variation, which is one of degree.

The historical antecedents of these variations are likely to be difficult to determine. Although some may be plausibly explained as results of population hybridization which can be observed in progress, it is likely that extinct populations also must be postulated, whose genetic composition cannot be known. There are in addition some hints of the way gene frequencies may change under selective influences; in the Rh blood group system it is known, for example, that certain matings may give rise to incompatibility between the antigens of the fetus and the antibodies of the mother, resulting in the death of a certain proportion of children and thereby the elimination of certain genes. It is probable that further examples will be found for other genetic characters. The gene frequency in a population tends, it would seem, to be held in equilibrium by opposing selective forces.

The adaptive nature of some of the more obvious physical variations in man, such as skin colour, has long been surmised, but it cannot be said that there is much direct evidence on the matter. Suggestive correlations between body proportions and the climatic situation of populations have been presented, but physiological work on the comparative performance of tropical peoples and Europeans has been inconclusive or has tended to show that any differences are slight. The prevalence of various nutritional and parasitic diseases in many non-European populations may affect characters and so be an obstacle to valid comparisons. Thus, although it might ultimately make contributions of great significance to the understanding of cultural variations between peoples, and although differences in the intensity and balance of physiological processes might prove to be factors in many differences in behaviour and temperament, the comparative physiology of man was only beginning to be explored in the 1950s. Much progress had to be made in psychophysiology before it would become possible from the study of comparative data at both the physiological and cultural levels to determine not only the range and the morphological associations of variations of bodily function in different populations but also the extent to which cultural dispositions are affected by such differences.

Meanwhile, the question whether populations differ with respect to inherited capacities in mental functioning is apt to be prejudged in the political sphere, for the basis of "racist" doctrines is the quite illogical supposition that if two populations exhibit certain physical differences which are inherited and also show differences in mentality, then the latter are inherited in the same biological sense as the former and, by implication, cannot be changed very much. The scientific study of psychological differences between populations is beset with grave difficulties. It is no longer generally believed that the intelligence tests so widely used in European populations are a measure of genetically determined ability uninfluenced by educational or other environmental features, and therefore applicable to other cultural groups. Insofar as tests as free as possible from cultural bias have been used in comparative studies, the results appear to favour the view that differences between populations are relatively slight and that the same kind of overlapping in range occurs that is characteristic of physical traits.

3. Ethnology.—As indicated above, most early anthropologists, encouraged by the success of evolutionary doctrines in biology, attempted to outline schemes of cultural and social evolution for mankind. They were handicapped by the fragmentary and restricted character of the material then available, but still more serious was their frequent misconception of evolutionary principles as developed in biology. Despite the stress placed on diversification in the latter, a single pattern of cultural and social evolution applicable to all human societies was usually postulated, and different peoples past and present were conceived as having reached various stages in this common process of development. This notion of unilinear evolution was applied both separately to particular aspects of human life such as modes of production, social organization, art, religion and law, and also to sociocultural development as a whole. In consequence, ethnography, *i.e.*, descriptive accounts of particular peoples, was apt to be regarded as a source of illustration of preconceived schemes, and the evidence it could afford of the divergence of cultural forms and of a consequent multilinear evolution of cultural patterns tended to be neglected. The monumental studies of Sir James Frazer, in which a vast body of earlier ethnographic data was compiled to illustrate the supposed evolution of certain cosmological beliefs and some primitive social institutions, represented the culmination of this approach.

As more detailed knowledge of nonwestern peoples accumulated it was, however, increasingly recognized not only that a priori schemes of evolution in such fields as technology, economy, religion, art and social organization failed to account for the facts, but also that any given cultural pattern or form of social organization had to be examined minutely and comprehensively as a functioning system if the nature of its various features was to be elucidated to afford an adequate basis for comparative and developmental studies. This has encouraged not only much more intensive ethnographic study in the field, but also, according to the particular aspect of culture and society concerned, a wider knowledge of the relevant branches of cognate sciences such as psychology and sociology. On these foundations, ethnology, the study of the his-

tory of peoples and cultures, made great progress in the first half of the 20th century. Ethnologists have not only been concerned with marshaling evidence to disprove the older schemes of unilinear evolution, as was so effectively done by R. H. Lowie, but have also sought, notably in the work of A. L. Kroeber, to work out by more empirical methods phases of cultural development in particular regions. Others have, however, sought to replace the earlier views by equally world-wide schemes based on other criteria. Influential among these was the *Kulturkreislehre*, the doctrine of primitive culture spheres first formulated by F. Graebner, which held that the more primitive peoples of the world could be classified into a limited series of distinct and ancient culture types, each characterized by a particular mode of livelihood, pattern of descent, form of religious beliefs, etc. These various types, it was held, had developed, spread widely and later intermingled, at successive periods in the early history of man. The task of the ethnologist was, accordingly, to unravel from the tangled skein of living primitive cultures the elements contributed in any given case by one or more of these ancient "spheres." Formal similarities in way of life, mode of descent, ceremonial, etc., among peoples as widely separated as, for example, the natives of west Africa, Melanesia and California, were held to show that their cultures had all in substantial measure stemmed from a single archaic type. This Graebnerian scheme secured little recognition in the English-speaking world where, indeed, its artificialities were severely criticized. But in continental Europe it not only exerted considerable influence on ethnological theory but also stimulated ethnographic field research, more particularly as its principles and methods were adopted and developed by the Anthropos school of ethnology under Father W. Schmidt and formed part of the training of Roman Catholic missionaries posted in all parts of the world.

In England and North America great stress has been laid on the comprehensive description of the many primitive cultures that have been fast disappearing or extensively modified under western influence. From the early years of the 20th century, under the influence of A. C. Haddon in England and F. Boas in the United States, a considerable body of systematic ethnographical data has been accumulated for certain regions of the world, notably North America, Australia and parts of Africa and Oceania. Comparative work based on such studies has, among other things, strengthened the evidence of the importance of migrations and mingling of peoples and still more of widespread diffusions of cultural elements, in spheres as diverse as handicrafts, art styles, mythology and ritual patterns, in modifying one or another aspect of culture over considerable areas. Attempts have been made to reconstruct such processes in detail for particular regions such as North America, Melanesia and Polynesia. The far-reaching effects of diffusion on cultural developments among all peoples thus became generally recognized. Its role and the processes involved were, however, exaggerated and oversimplified in the claims, which were generally rejected, of Sir Grafton Elliot Smith and William Perry, who attempted to account for the salient features of the more advanced primitive cultures of the world in terms of a single world-wide diffusion of their elements from one early centre of discovery and invention in ancient Egypt. Many of the assumptions underlying this scheme, and notably that of the inherent conservatism and uninventiveness of man, have been contradicted by the growing body of ethnographic and archaeological evidence pointing to the ubiquity of innovation under favourable conditions.

In the special conditions of the new world, where the historic record is less than five centuries old and a direct continuity was often to be found between prehistoric remains and surviving Indian cultures, American anthropologists have found a favourable opportunity for the study of cultural development by the integration or close co-ordination of ethnographic, documentary and archaeological research in the intensive study of the culture history of several major regions, notably in the southwest of the United States, meso-America (from central Mexico to Central America) and the Andean region of South America. During the second quarter of the 20th century regional specialists such as W. C. Bennett, G. Willey, A. Caso and E. J. Thompson succeeded in charting the main phases of indigenous cultural development and in elucidating many of the environmental factors and the processes of diffusion and integration involved. Historical and contextual problems have continued to multiply as this work has proceeded and been extended by F. Rainey, I. Rouse, J. B. Griffin, R. Heizer and others to further areas including the arctic, the Caribbean, California and eastern North America, the ultimate objective being to describe and analyze the entire culture history of the new world from the still unknown time when the first human communities reached it. Considerable advances have been made and it is only in parts of Europe and the middle east that a comparable completeness of the total cultural record of man has been obtained. These studies of ethnohistory in the new world have at the same time maintained contact with the more theoretical interests developing in cultural anthropology, and significant contributions of data and hypotheses in connection with such problems have been made.

4. Archaeology and the Cultural Record.—Prehistoric archaeology—the recovery and study of the artifacts of extinct cultures for which there are few written records or for which such records are not contemporary—had its systematic beginnings in the later 19th century in an anthropological context, and prehistorians, although now necessarily specialists on a limited area or period, have continued to interest themselves in the relation of their findings to the general problems of cultural development. The conspectus available, when the results of this archaeological research are combined with those of ethnology over a given period, makes it possible to grasp the broad outlines of the cultural history of mankind and to assess more effectively some of the main processes involved in cultural and social development. Archaeological materials, unlike documentary or ethnographic ones, can only rarely afford direct information concerning ideas or social relations. But despite the fragmentary and selective character of the material, significant, if limited, inferences can be reached in these fields when it is appraised thoroughly and critically.

For the reconstruction of culture history, the date of archaeological material is vitally important and systems of relative chronology have been worked out by various methods such as those based on correlations with geological horizons (for the more remote periods), the stratification of occupied sites and the associations and overlaps of typological sequences of artifacts. Absolute dating has presented greater difficulties, but in the ancient east it has been possible to estimate the chronology of the Neolithic and later prehistoric phases by working back from the oldest written documents including calendrical records, and the main phases of the prehistory of Europe back to *c.* 3000 B.C. have also been dated through correlations with these. In the arid areas of the southwestern United States it has been found possible, by matching the overlapping annual growth rings on tree trunks cut for building in prehistoric sites, to establish an absolute dendrochronology extending back to the beginning of the Christian era. But the development by W. F. Libby and others since 1950 of a method of dating organic archaeological remains by the measurement of the radioactivity of their carbon-14 promised to provide a means for securing an absolute chronology within a definable margin of error for prehistoric cultures as far back as 25,000 years.

The widespread existence of human populations in the old world during the Pleistocene Ice Age has long been established by the geological dating of the chipped stone tools that afforded cutting instruments for early man. For the earlier periods, however, fossil remains of man are generally few and isolated, so that attempts at correlation of the early Stone Age cultures with particular species of *Homo* remain speculative. Before and during the early part of the last glaciation, the Neanderthal species of *Homo* occupied Europe and parts of southwest Asia with a culture which included tool forms derived from several older traditions. But it appears to have been completely displaced in Europe during that glaciation by populations of *Homo sapiens*, precursors of which may have already existed there but which now appeared equipped with stone tools of new types. These Upper Paleolithic industries indicate a very great technical advance, as shown in the greater specialization of stone tools, many of which were intended not for direct use but for the manufacture of other implements in bone,

ivory and wood, and in the importance of missile weapons, especially the use of the spear thrower and bow, for neither of which is there any evidence in Lower Paleolithic remains. Advance in skill and organization in hunting and the addition of fishing to the economy permitted larger communities and more prolonged occupation of sites. The Lower Paleolithic phase in Europe had been immensely long and on a conservative geological estimate endured for approximately 400,000 years. The Upper Paleolithic and the immediately postglacial Mesolithic food-gathering cultures of Neanthropic man in Europe, although they cover by far the greater part of the known history of *Homo Sapiens*, were by comparison short-lived, for they began to be supplemented after less than 100,000 years by the cultivation of plants and the domestication of animals.

The foraging, hunting and fishing economies to which all known human communities had hitherto been confined were then effectively supplemented in the old world for the first time by the development of grain cultivation and stock breeding in the warm, open and seasonally watered uplands of the middle east about 6,000 years ago. This momentous innovation, which made still larger and more stable human communities possible, spread widely during the next 1,000 years and, as it was generally associated with the manufacture and use of polished (as distinct from chipped) stone tools, has become known as the Neolithic phase. Early Neolithic communities were small populations of from 20 to 30 households generally dependent on shifting cultivation, but, contrary to what prevailed in the hunting economies of Paleolithic man, a food surplus was increasingly possible in most environments to foster the development of other crafts. Handmade pottery and the weaving of simple textiles were generally adopted.

Despite the clear evidence of the widespread diffusion of Neolithic crafts from early centres in the middle east, it is by no means definitively established that this was the only region of the old world in which men independently developed primitive cultivation and a settled life. But it was in this region again that still greater technical advances followed in comparatively rapid succession over the next 2,000 years, facilitated it would seem by the devising of a more productive system of irrigation agriculture. New crafts, including the smelting of copper and the manufacture of bronze and later of iron for cutting tools, led to an increasing specialization of labour, a more extensive system of exchange and an increase in the scale and centralization of society. This gave rise to a succession of city-states and later of empires from about 3000 B.C. in various parts of the wide region from the Nile to the Indus. Deriving their food supplies from plow cultivation, and equipped with increasingly specialized artisan-made tools, utensils and ornaments, they developed complex systems of exchange and written records under systems of centralized government. Some of the crafts of these urban civilizations of the ancient east were progressively introduced to the surrounding Neolithic peoples, whose cultures were thereby elaborated and specialized in various ways. On these foundations, the classical civilizations of the Mediterranean were later developed, while the influence of the ancient east was probably a crucial stimulus in eastern Asia.

In tropical Africa archaeological research is in its infancy and the ethnographic record is very incomplete. It appears unlikely that the early Neolithic complex of the ancient east was able to breach the Sahara toward the west and there is so far no evidence of an early Bronze Age phase there. However, in the Ethiopian highland zone millet cultivation with the rearing of small stock and later of cattle, all probably derived from the north, appear to have afforded an early basis for sedentary and expanding populations. Together with ironworking, these occupations later expanded westward and southward over the tropical grasslands. South Asiatic root and fruit crops were also introduced and may have afforded the initial basis for cultivation and sedentary life in the forest zone.

Although Australia had been colonized much earlier by hunting peoples with Paleolithic equipment, the outer archipelagoes of Oceania, in Micronesia and Polynesia, may not have been effectively colonized by man much before the beginning of the Christian era, when there developed a complex series of movements by sea which appear to have originated from culturally advanced peoples of Indonesia. Subsequent and diverse but sporadic contacts between Polynesia and the new world remain a possibility.

Man first reached the new world late in geological time. Paleogeographical conditions suggest that any early route of entry was through the region of the Bering strait. But both the antiquity and the number of such movements into the western hemisphere now appear likely to be greater than was formerly thought. In the second quarter of the 20th century, evidence of the widespread existence of man in the new world as early as the late Pleistocene era accumulated. These earlier groups were hunters using chipped-stone spear points. They probably used the spear thrower but were ignorant of the bow. Much later, from some time after *c.* 5000 B.C., a considerable range of new equipment spread widely in North America and by its character and distribution suggests further migrations from northern Eurasia. On these foundations more complex cultures developed later in Middle America between central Mexico and Peru. Sedentary life in small agricultural communities appears to have become widespread well before 1000 B.C. and was based nearly everywhere on the cultivation of primitive forms of maize, beans and cotton, to which many other plants were added later in different areas. Pottery also soon became general. Although there are many uncertainties as to the location and character of successive cultural advances, this wide Middle American region is generally accepted as a single cultural continuum within which, by processes of diffusion and of adaptation of discoveries and crafts, a Neolithic village economy of basically similar type was established. It would appear, however, that transmissions over wide areas were largely confined to knowledge of basic techniques and materials, for styles and emphases varied widely in different regions, providing the foundations for distinctive later developments whereby, more than 2,000 years later than in the old world, several complex civilizations were gradually built up after 1000 B.C., with their main centres in central and southern Mexico and in western Peru.

There are no clear indications of cultural connections with the old world in the earlier development of the older Middle American agricultural peoples, but the question of cultural effects of sporadic transmissions from Asia across the Pacific in the later phases is still an open one. It is claimed that certain elements of art style and ceremonial in the late Maya resemble contemporary southeast Asiatic forms, while there is also evidence to suggest that food plants spread west across the Pacific from the new world in pre-Columbian times. On the other hand, the significant and widespread effects of the diffusion of crafts and other cultural elements from Middle America over surrounding regions within the new world is undisputed.

Thus in both the old world and the new, a succession of discoveries, inventions and adaptations to new conditions made in different centres through the millennia and diffused to other peoples over wide areas gave human populations a progressively greater control over natural resources and resulted both in a growing complexity of cultural apparatus and an increasing scale and differentiation of social organization. Despite the setbacks or stagnation of some peoples there were always centres of development, and the cultures of the multiplying human societies were continually diversifying. The archaeological record thus confirms the 19th-century hypothesis that savagery (food-gathering), barbarism (nonliterate primitive cultivators) and civilization (literate societies organized in states with specialized occupations and class structure) have been consecutive phases in the history of mankind, but it equally refutes any idea that there has been an inevitable tendency for all peoples to pass autonomously and successively through such stages. The growth of human culture has clearly been an immensely complex process of discovery, innovation, diffusion and adaptation. (*See* also ARCHAEOLOGY; GEOCHRONOLOGY.)

5. Analysis of Culture and Society.—Parallel with the advances in ethnology and prehistoric archaeology, a distinct field of interest in anthropology has been greatly developed. This has stemmed from the desire to reach by more intensive and systematic

study, and as part of the general scientific study of the nature of culture and society, a clearer grasp of the inner workings of nonwestern societies and of the *raison d'être* of their customs and institutions. This could not be attained from the study and comparison of outer forms and led to a functional analysis of sociocultural systems as viable entities. A few fortunately situated and gifted observers had already made intensive studies of the lives of some primitive peoples, not in order to provide data for ethnologists or to illustrate evolutionary schemes, but with the object of discovering the internal processes and conditions and the inherent values which sustained and mutually adjusted the different aspects of their way of life. Robert H. Codrington's *The Melanesians,* Frank H. Cushing's *Zuni Breadstuffs* and Henri P. Junod's *Life of a South African Tribe* are early classics of this kind. The theoretical aspects of such an approach had hitherto received but little attention within anthropology itself mainly on account of the evolutionary or historical preoccupations of ethnologists. But within the framework of evolutionary anthropology there had been considerable achievement in analyzing and classifying the forms of primitive social organization. After J. J. Bachofen and Sir Henry Maine, whose main work was published in the 1860s, the great American pioneer Lewis H. Morgan, in his *Systems of Consanguinity* (1871), laid the foundation for a scientific analysis of kinship systems. Fifty years later, R. H. Lowie, in his *Primitive Society,* published a masterly critique of older theories which also surveyed and classified in the light of more recent ethnographic knowledge the whole range of primitive social groupings and the conditions which gave rise to them.

Meanwhile, in considering theoretical problems concerning the structure and function of human societies, a number of sociologists, notably Max Weber, Georg Simmel, Emile Durkheim and Marcel Mauss, had turned to the ethnographic literature on primitive peoples for material. Under their influence the application of such a functional approach to the study of primitive people was developed in England by W. H. Rivers, A. R. Radcliffe-Brown and B. Malinowski. But they stressed a new and essential point of method, namely, that the field study and the theoretical analysis of the ethnographic material should be carried out by the same investigator, who should go into the field not to record his findings according to a more or less routine schedule for the use of others but to investigate at first hand the living situation among a particular people and elucidate particular problems concerning the nature of culture and social organization. A. R. Radcliffe-Brown in his first studies on the Andaman Islanders (1906–08) analyzed the interrelations between their ecology, social organization, religious practices and symbolism. The Melanesian field work of B. Malinowski (1914–18) provided the basis for a detailed demonstration of the intricate interdependence of cultural norms and for an analysis of the social processes whereby patterns of customary activity were maintained and restored among the Trobriand Islanders. These studies laid the foundations of what is generally known as functional anthropology, which, while it has considerably developed its range of theoretical interests, has continued to stress the importance of intensive and comprehensive field work as the chief means of formulating and testing hypotheses concerning cultural and social processes and the roles of institutions. While Malinowski himself devoted his main attention to the ways in which the cultural system integrated the activities of a people and molded the outlook of the individual, providing for and co-ordinating the wide range of human needs which he traced back to their biological and psychological foundations, later work under Radcliffe-Brown's influence was more sociological in the sense that it sought to analyze various sectors of the complex system of social relations and compare them over a wide range of societies. It examined the functions and interrelations of institutions, constructed models of social structure and, through the comparative study of these structural features in different societies, sought to show both the interdependence of their elements and the conditions sustaining them. As was shown in later studies, such as those of R. Firth and E. E. Evans-Pritchard, the close observation of social relations in the field afforded a more adequate basis for the analysis of economic processes, social control and ritual activities and belief.

In the course of these developments new methods of field investigation have been elaborated and systematized to provide the data required for tackling these problems, which are concerned only initially with the externals of any cultural feature, be it a technical operation or a complex institution, and are mainly directed toward an analysis of its role in the sociocultural system of which it forms a part. While the study and description of cultural forms is always essential and may suffice to establish the occurrence of technical and stylistic changes and connections between patterns in different cultures, a functional approach of this kind is indispensable in attempting to isolate and analyze the processes involved in the integration and internal development of cultures and social systems. It has, in turn, raised many problems of theory and method which have loomed large in anthropological discussions, for the concept of function has itself been given various connotations. While Malinowski conceived it primarily in terms of the needs and motivations of the individual members of society by whom modes of satisfaction were elaborated in cultural terms, Radcliffe-Brown insisted on a more strictly sociological connotation directed toward the analysis of social structure and the function of institutions and beliefs as contributing to the maintenance of a given social system. While the approach in particular studies has often varied according to the material or the special problems in hand, and both motivational and structural analyses have sometimes been combined, the distinction in the two trends has been marked. The former has predominated in the United States, while structural studies of systems of ideas and social organization have predominated in the researches of British social anthropologists. (*See* also SOCIAL ANTHROPOLOGY.)

6. Cultural and Social Typologies.—The need for comparative study of functional relations, in order to define recurrent social and, as evidenced in the work of J. Steward and R. Redfield, cultural types and the conditions on which they depend, has also received growing recognition. Although systematic work is only beginning in this field, it has long been apparent that there are significant functional homologies between diverse societies which are manifested not so much in concrete cultural forms of behaviour as in more abstract qualities such as levels of material productivity and social aggregation, degrees and patterns of occupational specialization and of horizontal and vertical social differentiation. Typologies of this kind have long been recognized in the implicit classifications of types of social organization such as those distinguishing kin-based from various types of state systems, recognizing among the former such recurrent subtypes as the localized bilateral band, the polysegmentary lineage system and, among the latter, feudal and bureaucratically centralized varieties. Further comparative study promises to yield not only a more precise formulation of types but a more exact knowledge of the ecological, technical and demographic conditions to which they are related. Such typological studies are necessarily based on selected and abstract features. They seek to determine not the genetic and historical relations between peoples or cultures but the ways in which features common to certain societies are functionally related, through regular psychocultural processes, to particular kinds of external conditions and the nature of the cultural adaptation that is demonstrated by the recurrence of particular types in diverse places and periods.

7. Culture and Personality.—Theoretical interests in American anthropology, following up the early leads of A. L. Kroeber, C. Wissler and E. Sapir, included the pursuit of more comprehensive and explicit analyses of cultural phenomena and the study of the relations between different aspects of culture. This has led to a concern with the ways in which the personality and outlook of the individual are modified by the cultural system.

This approach, which first became widely known through Ruth Benedict's *Patterns of Culture* (1934), has been developed in scope and refined in technique in the works of Margaret Mead, Irving Hallowell, Clyde Kluckhohn and others, which have led to a fusion of interests between anthropologists and personality psychologists. Primitive peoples, distinctive and diverse in their

ways of life and comparatively isolated from the western world, not only show marked variations in their predominant patterns of emotional expression but have also afforded smaller-scale and more homogeneous units for the study of the cultural aspects of such problems as compared with those available in western societies. Anthropologists have accordingly sought by systematic field observation to discover the underlying and pervasive attitudes characteristic of particular peoples and to analyze the ways and conditions in which these differ. This has involved attempts to devise more objective criteria for defining the differences in temperament that have long been recognized by ethnographers, historians and others at the common-sense level. Besides directing attention to hitherto neglected cultural minutiae and so to formulating more precisely the "covert culture," it has led to the adaptation for anthropological use of projective tests devised by psychologists to reveal traits of personality; and also to a detailed examination of modes and emphases in child training among different peoples in connection with psychological hypotheses concerning the profound effects of the cultural setting and human relations in infancy on the adult personality. These approaches all derive from the view that the members of any persisting group of people will not only exhibit distinctive cultural features but will also manifest certain predominant traits of personality. The nexus between these is sought in the fact that the integration of experience by the individual and the maintenance and transmission of a cultural pattern involve the same psychological mechanisms whereby particular forms of apprehension and behaviour acquire an emotional and symbolic significance as part of a meaningful world of experience.

This approach has directed the attention of anthropologists to the symbolic meanings and emotional significance of cultural features hitherto only formally described and, on the other hand, has led psychologists to recognize the existence of an inevitable cultural component which, equally with biological endowment, immediate stimuli and neurological mechanisms, affects all processes of perception, motivation and learning. A human being, therefore, always perceives, feels, thinks and acts as a person sharing culturally derived characteristics with his group.

8. Culture and Society.—The distinction between cultural and sociological analysis, which is important in connection with these more recent developments, is one on which there has been much confusion. Both these terms have been taken from common speech and are often loosely used, but the distinction between their central meanings corresponds closely to significant differences of objective in much anthropological work, and there is an advantage to be gained from stricter usage. The term culture refers to the standardized patterns of activity and belief that are learned and manifested by people in their collective life. It includes categories as diverse and various in form and in range of significance as speech, craftsmanship, games, rituals, empirical knowledge and metaphysical beliefs. It consists essentially of certain kinds of regularity which are abstracted by the observer from the continuous flow of human activity, and from which he can infer a range of recurrent emotional attitudes or established values. Such cultural patterning is, of course, universally recognized. The anthropologist differs from the layman only in more fully appreciating the fact that this recognition involves abstraction and conceptualization, and in consciously attempting to formulate and analyze such patterns systematically in order to study their interrelations and implications. Among any given people the number and variety of cultural features that may be isolated for consideration are indefinitely great. It is, indeed, because the data and the corresponding problems are so diverse, ranging as they may from concern with the technical aspects of a productive activity or the formal analysis of an art style to the study of ideas implicit in actions and statements concerning religious belief or moral judgment, that anthropological studies of different aspects or fields of culture are so diverse and link up with problems in so many other recognized fields of knowledge. The kinds of inquiry that can be made about such patterns are, accordingly, quite various. Cultural features may be studied in sequence to determine changes through time in one or more continuing populations. They may, on the other hand, be isolated in order to discover the degree of interdependence among them and between them and selected extracultural conditions.

Sociological analysis, on the other hand, is essentially concerned, not with cultural forms, but with relations between categories of persons and the structure of the groupings they form. It operates with concepts such as social status, dominance and subordination, opposition and solidarity as applied to persons and groups. These concepts are also derived from the observation of a multitude of recurrent items of behaviour between individuals, certain aspects of which can be summarized in terms of such kinds of relationship. Thus the formulation of social relations is derived from observation of the same concrete collective activities in human populations as are cultural patterns, but they are abstracted in a different frame of reference. Since categories of social relations are often abstracted from certain recurrent patterns of behaviour they can be regarded as derived from, and more abstract than, cultural patterns. Furthermore, for their analysis attention is restricted to particular kinds of cultural patterns and to limited aspects of these, namely, those from which the relations between persons in a social system can be derived.

9. Science and History in Anthropology.—These various attempts to isolate and analyze the different factors underlying any given cultural or social feature and its changes through time have sustained critical interest in the problem of universal processes which, in differing combinations in particular situations, might account for the distinctive features of actual sociocultural patterns and for the differences among them. The variety of human cultures recorded by ethnography provides a laboratory in which, through the analysis of differing forms with their varying functions and contexts, such processes can, at least in part, be isolated by comparative study. This is the more strictly scientific or analytic approach in anthropology. It seeks to abstract from a given range of phenomena certain properties or attributes between which definite relations can be discovered. It does not seek to account in any one analysis for all the features of any concrete sociocultural situation or development. Selected properties are isolated for study in relation to others that may thus be found to be the preconditions of the first, or functionally interdependent with them.

At the same time, the direct and comprehensive interest in the concrete human situation, whether it concerns a general pattern of culture, a mode of social organization, particular forms of belief and ritual practice or techniques whereby artifacts are produced and employed, leads to explanation through integrated description or historical interpretation. Particular configurations are appraised and interpreted with regard to their contexts and antecedents. But integrated descriptions, which are the stuff of history, are themselves dependent on analytical hypotheses, for no explanatory account of how things have come to be as they are among a given people is possible without postulating more general properties and regularities with regard to human culture or social life. Thus, descriptive studies, whether they are what are commonly regarded as historical, tracing particular cultural and social developments over a considerable period of time, or whether they are ethnographic descriptions of very limited time depth, and, whether the range of activities and relations considered is wide, or is confined to the portrayal of a particular institution, always depend for the interpretation of the particular forms and their interconnections on the application of general principles posited as underlying the sociocultural behaviour of man. In this sense historical or descriptive studies are a species of applied science; for, just as the various branches of engineering depend on the postulated uniformities of the physical sciences, or as modern medicine depends for diagnosis and therapy on the application of biological concepts and principles, so the analysis and interpretation of particular cultural situations presuppose principles concerning human behaviour. The concepts and theories employed may be vaguely formulated; they may not be explicitly stated. Their verification may be weak and some may be shown to be irrelevant or fallacious. But conceptually they are of the same kind as the hypotheses and theories of natural science, for

a scientific theory is the most satisfactory hypothesis available at a given time, in respect of verification and comprehensiveness, concerning the properties of a certain range of phenomena and their interrelations.

The reasons why hypotheses concerning processes in human society differ in degree of explicitness, precision and verification from the theories of physical science, and are correspondingly more limited in their analytic and predictive value, are not far to seek. For in passing from the inorganic to the organic, and from the organic to the cultural field, the complexity and variability of the phenomena, *i.e.*, the number of variables involved in determining their properties, multiply progressively. So, too, do the difficulties of achieving systematic observation in requisite varieties of circumstance. Where, as in the study of the collective activities of man, the range and relative independence of the variables that determine any section of the pattern are so great, it is not surprising that hypotheses are, as compared with those in physical science, difficult to formulate, verify and apply. They are nevertheless of crucial importance. For every people has its own hypotheses as to various processes controlling its cultural activities and its social relations. Everywhere these beliefs are employed in explanation of the events that befall a people and in its judgments regarding the practical courses it should pursue. Hypotheses are also extended to other peoples, past and present. That such beliefs can often be shown to be inadequate or fallacious only serves to underline the fact that the particular cultural and social conditions in which men find themselves will be interpreted, and indeed can only have meaning, in terms of theories of culture and of society. From this follows the paramount importance of applying to sociocultural phenomena the inductive analysis and the critical testing of hypotheses which are the canons of science. In attempting such analyses anthropology has emphasized the need to consider particular problems within a framework that embraces the human species as a whole. Whether concerning the elaboration of particular crafts, the character of an art style, the pattern of economic or political organization or the foundations of religious beliefs and practices, the anthropologist eschews hypotheses of special creation.

10. Human Ecology.—Beyond the analysis and comparison of cultural patterns or social systems themselves there lies a further range of problems concerning the relations of such patterns to external conditions. The recognition of culture as, in significant measure, an instrumental apparatus for the satisfaction of psychobiological drives in man accounts for the universality of several broad categories from which any given culture can be viewed, such as the technical, economic, political or magico-religious, and for the common attributes of any social system in providing means of training, control and replacement of its personnel in various social roles. But the great variability in the content and context of this instrumentality remains a major problem of the student of culture and society and points to the need for closer analysis of the wide range of external conditions in which the cultural and social adjustments of any community are made. The physiological and psychological qualities of individuals, and thus of the groups they comprise, are variable; hence special characteristics in this field may prove to be significant determinants. The understanding of the significance for culture of physiological and psychological processes and of their variable incidence is obviously dependent on the advances made in these sciences by their own methods. This is but another instance of the familiar interdependence between different fields of science whereby one branch employs concepts and inferences whose validity depends on findings in other fields. The pervasive influence of the habitat and of past and present relations with other communities on the way of life, social institutions and outlook of any people has also long been recognized and often effectively presented in descriptive accounts. Although the subcultural or biopsychological foundations from which any cultural pattern must develop may account for certain universal qualities or categories, in the sociocultural field differences in habitat, resources and relations with other groups continually tend to produce great variety in the development of cultural patterns and social relations. Any explanation of cultural variation and of specific cultural and social features must, therefore, include an ecological approach in which these are comprehensively related to the biological and demographic character of the particular population, to the available material resources, to the techniques commanded and to the connections with other groups.

Cultural adaptation and social change are, however, profoundly affected by the inertia of the previously existing pattern. For the various elements of any cultural system inevitably acquire a symbolic value over and above their more direct instrumental significance. Emotional satisfactions and recognitions of social status become attached to them in such a way that the possibilities of modification and innovation are restricted and channeled by the already existing configuration. Thus the adaptive processes may be slowed down and biased and there may be not only a marked discrepancy between potentiality and achievement in any cultural sphere but also discordance between one part of the field and another under conditions of cultural change. Such maladjustment or discrepancy is equally apparent at the social level and has been the subject of close study in connection with the effects of the impact of western civilization on primitive societies. (See *Applied Anthropology*, below.)

An ecological approach of this kind views the biological, environmental, demographic and technical conditions of the life of any people and its previous patterning as an interrelated series of determinants of form and function in human cultures and social systems. It recognizes that a pattern of group behaviour is dependent for its maintenance upon the persistence of a specific range of resources and associated skills and upon a body of emotionally charged beliefs; these together give rise to a system of social relations that can be analyzed as a series of social structures. All of these are implemented by learning, or enculturation, on the part of the many human beings who participate in the sociocultural system and so maintain it. As such a system is at the same time a field for the release of human energies—the level of which is likely to be significantly dependent on biological factors—"racial," nutritional and immunity differences among peoples are likely to feature among the ultimate determinants of cultural and social differentiation. Human ecology, therefore, deals with a very complex series of interconnected systems in which the resultants in one are partial determinants in the others. As in the physical sciences, therefore, knowledge of relations and intensities in one system is needed to provide data for analysis and interpretation in others. Although the anthropologist, in investigating a particular problem or constructing a model of any one system, may neglect the many variables arising from others, it is in the recognition of this wide field of interdependence and of the need to integrate them in the final analysis that the outlook of anthropology, as distinct from that of any of the more limited approaches to human behaviour, essentially consists. (*See* also Ecology.)

11. Cultural and Social Evolution.—Although the common 19th-century misconception of a unilineal and progressive development of all human societies has long been discredited, the validity of the basic concepts of evolution has been confirmed. The cultures and social systems of mankind have shown the same general trend toward increasing complexity and differentiation through time as that found in organic evolution. There are accordingly many analogies with organic evolution in cultural development. Cultural innovation as one emergent manifestation of the most elaborate life form shows the same propensities found in life itself for the development of new forms and functions, for the radiation of forms that are more successfully adjusted to a given range of environment and for the reduction or extinction of other forms with which these compete successfully. But the processes involved differ basically from those in organic evolution, for they are psychological and not genetic, the units of modification are social groups and not individual organisms, and they include processes of assimilation which are not matched at the organic level. For whereas organic evolution depends on the transmission, perpetuation and recombination of new biological features or mutations through the processes of reproduction, cultural mutations

arise from the inventiveness of socially stimulated individuals and are established by precept and learning. If a cultural innovation is accepted in a population, the new patterns of activity and thought can be transmitted to all appropriate members of the succeeding generation and will furthermore not be restricted to that population but can be extended by diffusion to all the other receptive populations in contact with it. Cultural entities again appear to be more complex and fluid than genetic ones; the patterns of behaviour and mentality in which they are manifest can be subtly modified in the process of transmission and incorporation into a wider cultural system. Thus cultural and social evolution can proceed much more rapidly to produce a wide range of variations and, on the other hand, a successful cultural pattern can radiate much faster than a biological species. The result, moreover, is to produce not new species composed of many members closely resembling one another, but a new source of diversity in the many communities that come under the influence of a radiating diffusion. (D. F.)

12. Linguistics in Anthropology.—Although European linguistics developed from earlier philological studies, American linguistics began primarily as an anthropological discipline and has developed in close conjunction with ethnology, the science of culture. Nearly all of the early students of anthropology in the United States engaged in linguistic studies and regarded these as essential to a thorough knowledge of culture.

American linguists paid especial attention to the languages of the American Indians. In this field the major problem was to find a way to describe accurately a large number of highly diverse languages which had neither a written literature nor a documented history. Under the leadership of Franz Boas, American anthropological linguists concentrated on descriptive rather than historical studies. Their aim was to analyze and describe languages, not in terms of their historical antecedents (which were unknown) or in terms of traditional grammatical categories (which were inapplicable), but solely in terms of the structural and semantic categories evidenced in the languages under study. Such research required more than simply linguistic analysis; the Americanist also needed a sound knowledge of the culture to which the language belonged.

As a result there developed an interest in the relations between language and culture and in the role that language might play in the habitual behaviour and thought of its speakers. Boas (in 1911) suggested that linguistic inquiry is necessary to a thorough investigation of the psychology of the peoples of the world and especially important to an understanding of fundamental ethnic ideas. Edward Sapir, in 1916, investigated the contributions made by historical linguistics to the reconstruction of cultural history. But Sapir went further when he proposed (1931) that a thorough description of a linguistic structure and the ways in which it functioned in speech might throw considerable light on the perceptive and cognitive faculties of men and help in understanding the wide diversity in behaviour among peoples of different cultural backgrounds. Anthropological linguistics, as contrasted with linguistics per se, became concerned not only with the scientific study of language but also with language as an important influence in the molding of cultures and in the orientation of human thinking.

One of Sapir's students, Benjamin L. Whorf, took up this problem in a series of brilliant essays written from 1939 to 1941. This work, cut short by Whorf's death, led to further investigation of a problem which turned out to be bristling with complex and difficult questions. Some of these centre about the role of language in its cultural matrix. How do the patterns of a language (grammatical and semantic) relate to other cultural patterns? Does language exert a shaping influence on culture, and vice versa? The study of these problems (often called ethnolinguistics) has only begun, and much research is needed even to determine whether or not the questions raised are genuinely valid.

A second set of questions relates to the influence exerted by language on perception, cognition and thought. Here the terrain is less well explored, even though the problems have long been studied by linguists, psychologists, philosophers and others (*see* especially the work of the Neo-Humboldtians). A review of these problems in 1959 came to the conclusion that an understanding of the systemic conception of language presented by linguistic science was essential to the solution of many important problems of psychology. The language a people speak may well influence their thinking, but the problem of determining the precise nature of this influence remained to be solved. *See* also LINGUISTICS.

II. PHYSICAL ANTHROPOLOGY

Physical anthropology is that branch of natural science which is concerned with the origin and evolution of man. Both the course which human evolution has taken and the causes or processes which have brought it about are of equal concern. In order to interpret the diversity within races and between races it has been necessary to search for the meaning of these differences by including as objects of study past races of fossil man as well as the nonhuman primates: anthropoid apes, monkeys, tarsiers and lemurs. Much light has been thrown upon man's relation to other primates and upon the nature of the transformation of his skeleton in the course of evolution from early man to modern man, a span of at least 500,000 years. Discovery of the South African man apes, the first in 1924, and of a similar form (*Zinjanthropus boisei*) in east Africa in 1959, has revealed unanticipated data concerning the diverse combinations of traits which can coexist and the singularly illuminating fact that erect posture preceded the great expansion of the brain in human evolution.

Many of the processes responsible for the differentiation of man into different races, although he still remained a single species, *Homo sapiens*, are known: selection, genetic drift, migration and mutation. Objective methods of isolating various kinds of traits and dealing mathematically with their frequencies, as well as their functional or phylogenetic significance, make it possible to understand the composition of human populations and to formulate hypotheses concerning their future. The resulting information accumulated by physical anthropologists makes available facts about the groups inhabiting the world as well as the individuals composing these groups. Thus, it is possible for a person to learn about his own genetic constitution with reference to traits ranging from blood types to the fissural patterns of his molar teeth and to know the frequency and distribution of these traits in the various races about the world. He is also able to secure some estimate of the probability with which his children will inherit these features.

Insight into the field of physical anthropology may be obtained by reviewing the general fields of investigation in which particular researchers are actively engaged.

1. The relationship of the human organism to its environment, or human ecology, is a bridge between the biological and social sciences. Problems of population, size and stability are important in many ways. A very immediate aspect is the varying rate of change which may occur in populations of different sizes. Theoretically, a small population is more susceptible to chance fluctuations than a large one. Both the natural environment and the economy of a particular society affect the population size. (*See* ECOLOGY: *Interactions of Populations.*)

2. Human evolution is another area which serves as a focus for research. The essential problems are not only the complete description of fossil forms but the evaluation of the significance of particular traits. Old concepts of orthogenesis, or evolution in a straight line, have had to be abandoned, and radiant and parallel evolution have come to the fore. It is clear that the course of human evolution may swing about so that what were formerly considered relatively modern forms may actually precede morphologically earlier ones, as in the case of the more modern

kind of Neanderthal man who apparently preceded the more primitive or early form. Fossil man of considerable antiquity has been found in Europe, Asia and Africa. No area in the world is without skeletal remains, so that researchers may everywhere engage in skeletal studies. (*See* MAN, EVOLUTION OF.)

3. Primatology is an area in which man's place in nature is no longer the major point of focus. Researchers are concerned with experimental, medical and ecological aspects of primates and it is from these studies that much of the functional significance of various bone and muscle complexes has been derived. The different kinds of adaptations which groups of monkeys have made to life in the trees or to life on the ground have had many consequences in the proportions of their limbs or in the elaboration of various groups of muscles. Similarly, the mode of progression through trees by the use of the arms, known as brachiation, is accompanied by the elongation of the arms, reduced size of the thumb and many other structural arrangements in the anthropoid apes. Thus the primates provide a natural laboratory of many kinds of experiments in physical adaptation to fundamentally different ways of life or adaptive zones. (*See* PRIMATES.)

4. Genetics is a fourth major area of research. The study of inherited traits in individuals and the behaviour of the genes responsible for these traits in populations is essential to understanding human variability. Although the blood groups have provided the bulk of the data, many other traits are being analyzed and theories of their inheritance tested. As a result of research in this area it is possible to describe races in terms of gene frequencies and to calculate amounts of race mixture. (*See* GENETICS OF POPULATIONS.)

5. Growth studies, both of humans and other primates, engage the attention of many physical anthropologists in medical and dental schools as well as in independent clinics and universities. Methods of assessing rates of growth, skeletal age compared with chronological age and the genetic, endocrinological and nutritional factors are some of the aspects involved in these studies. The relation between growth and socioeconomic status and other cultural features receives considerable attention. Dentitions have been frequently studied, often because the emergence of the teeth is of great practical importance and serves as an index of development. As a result of research in this area it is possible to describe races in terms of gene frequencies and to calculate amounts of race mixture.

6. Measurement or anthropometry (*q.v.*) has been a mainstay of anthropological research for well over a century. More attention is being given to the judicious selection of measurements than to the simple techniques with which calipers are handled. Many traditional measurements cannot be analyzed and the addition of multivariate statistics does not make them any more intelligible. Statistical considerations are especially important in genetic and anthropometric research, and part of the history of statistics is identical with the history of the development of these two research interests. Quite certainly the end results of growth can only be studied by measurement. Newer growth studies have followed children through their morphological and biochemical changes with the aim of discerning why children grow.

7. Many of the applications of physical anthropology lie in the field of measurement. Thus, the problems involved in providing military and civilian clothing for large numbers of people depend on measurement and statistical treatment. Substantial savings have been made possible by measuring the people of a particular area and adjusting the clothing tariffs to these known distributions of body sizes. There is sufficient variation within most countries so that the geographical variations in size of the body and intermembral proportions are of practical importance. Human constitution is another area of research interest. Several descriptive systems exist for classifying persons who vary from a lateral or relatively squat body build through a relatively muscular to a linear body build. The components of body build, the different tissues and dimensions, were being studied in the early 1960s by means of factor analysis and comparisons of siblings and twins, and their actual mode of inheritance and response to environmental conditions were slowly being specified. The various areas of interest referred to above are, of course, not mutually exclusive; ideally they should all form part of the training of researchers in the origin and evolution of man. (*See also* GROWTH.)

A. IDENTIFICATION OF SKELETAL REMAINS

Law enforcement agencies frequently call upon physical anthropologists to identify skeletal remains. A summary of the kinds of information which may be derived from a skeleton, and the method by which they are secured, provides an index of the usefulness of skeletons. Under optimum conditions, seven categories of information may be derived from the examination of a complete skeleton, or one which is at least represented by the skull and mandible, the two hipbones, and some long bones such as those of the thigh and upper arm. With varying degrees of precision estimates may be made of the sex, age, stature, race, bone diseases, individual structural peculiarities, such as right- or left-handedness, and the major blood type, O, A, B or AB. These determinations are based upon measurements and observations of the morphological characters. The 20 or 30 measurements commonly used indicate the absolute size of the various portions of the skull and other bones. Indices expressing the proportion of one diameter to another may be derived from these. The cranial index, the proportion of the breadth of the head expressed as a percentage of the length, is often useful when distinguishing Negro crania, which are often relatively narrow and long, from American Indian crania which, in many groups, are broader. Morphological observations may be made of a great number of characters, though about 30 are usually adequate for most purposes. These observations are of two kinds: (1) form or conformation (*e.g.*, the foreheads of Negro crania are often bulbous whereas the foreheads of Australian aborigines are more often flatter and more sloping); (2) the presence or absence of discrete traits or configurations (*e.g.*, the upper front teeth of Mongoloids often have a depression on the posterior or lingual surface, known as "shoveling," and the first lower molars of Eskimo crania most often have five cusps). Combinations of traits based on size, proportion, presence or absence of particular items, are distinctive of different populations, and thus an individual skeleton may be classified as a member of a particular group. Age of the individual skeleton is estimated primarily from five principal characteristics: (1) appearance of epiphyseal centres; (2) formation and emergence of deciduous, then permanent teeth; (3) union of the end of the long bones with their shafts, many of which unite between ages 13 and 19; (4) changes in the surface conformation and texture of the faces of the pubic symphysis; (5) closure and obliteration of the cranial sutures separating the bones, many of which gradually unite between the ages of 21 and 65.

It should be kept clearly in mind that identification of a single skeleton is an application of the data concerning combinations of characters which are secured from many other studies of a large series of skeletons from known populations. In the sense that each specimen is unique, this application of research does not contribute to generalization. In the same way, a single specimen of fossil man is of limited utility in constructing a body of knowledge about a population. The fact fundamental to the identification of a single skeleton or the attempt to place a single fossil find in its relation to other fossil men is that a single individual is not a race. A race is a population and is always variable in its physical characteristics. Some skeletons may be more easily identified with reference to the population from which they were drawn owing in part to the fact that the population is relatively homogeneous, the range of variability is known for that population and the population is relatively distinct from others. The eastern or arctic Eskimo skull is comparatively easy to recognize because it is characterized by a high frequency of nine or ten traits: (1) the skull is relatively long and narrow; (2) a ridgelike elevation extends along the top from front to back; (3) there is a marked protuberance of the occipital or rear portion of the skull; (4) the face is extremely broad; (5) cheekbones are prominent and form a sharp angle at the turn from the face to the side of the skull; (6) the nasal bones are narrow; (7)

the tympanic plate is often thick; (8) a dehiscence or aperture may be present; (9) the mandible, which is large, often has a torus or bony reinforcement on the inside; and (10) a bony ridge may also occur on the palate. Combinations of sorting criteria such as these are assembled for each skeletal population and they enable the anthropologist to estimate the likelihood that an individual specimen belongs to such a population. In many groups there is so much overlap that an individual cannot be assigned to one or the other. Thus, there are some American Indian crania which resemble those of Australian aborigines on the basis of the sorting criteria commonly employed, and this similarity has given rise to fallacious theories of Australoid migrations to the new world.

The major blood type of the skeleton may be determined because blood group substance is present in several tissues and fluids of the body, including the spongy tissue found inside the vertebrae and the heads of the long bones. This group substance is also situated on the red blood cells and responds to the typing serum containing the antibodies by agglutinating or clumping the red cells together. Although it is not possible to agglutinate the bone cells, an absorption technique can be employed which will indicate the presence of the group substance for A or B in the bone by reducing the titre of the serum specific to it when the two are placed together in a test tube. The group substance may be extracted from the bone and tested separately. This technique might prove to have great future significance in that it makes possible the tracing of the genetic composition of various skeletal races back in time, since the group substance is very stable and resistant to alteration.

Another kind of test which may be applied to skeletal material is that of the fluorine-dating method. This is a chemical test which measures the amount of fluorine present in the specimen. This amount may then be checked with that found in other bones from the same deposits and their contemporaneity established. In addition, the relative amount of fluorine varies with geological antiquity, though it must always be related to the amounts found in specimens from a particular site. Thus it is possible to secure a reliable estimate of the antiquity of skeletons. This method enabled the British museum to announce in 1953 the relatively recent age of the Piltdown skull and to demonstrate that the mandible associated with it, an object of much dispute because of its simian appearance, did not belong with the skull.

B. Old and New Concepts in Physical Anthropology

1. Early Investigations.—Inasmuch as the history of physical anthropology is, in large part, a history of man's attempt to determine his place in nature, to compare himself with other primates and to interpret the physical differences, more is to be gained from examining the kinds of problems which have been studied and the nature of the evidence that has been used than from reviewing the succession of great names. Twentieth-century familiarity with primates tends to obscure the fact that the precise distinction between man and the apes, based on evidence secured from actual dissection, had not been made before 1699. At that time Edward Tyson published the comparative anatomy of a chimpanzee and correctly deduced that the chimpanzee was not a human being. Succeeding Tyson is a distinguished series of men who launched into the formidable task of describing and classifying human beings as well as the other primates. Georges L. Buffon, Immanuel Kant, Johann Friedrich Blumenbach, Jean B. Lamarck and Georges Cuvier in the 18th century all made notable contributions. Of these, Blumenbach (1752–1840) is recognized as the father of physical anthropology. Although many early classifications of human races failed to distinguish between physical and cultural characteristics and leaned heavily upon the concept of primordial types with a corresponding minimization of variability, it is noteworthy that Blumenbach as early as 1775 observed that the "innumerable varieties of mankind run into each other by insensible degrees." He also initiated use of the term Caucasian to describe members of the white race, basing the choice of this term upon the race of men of Georgia on the southern slope of the Caucasus mountains who enjoyed a remarkable reputation for beauty. Blumenbach anticipated 20th-century analyses of locomotion in his critical observation that the chimpanzee was essentially quadrupedal in spite of occasionally erect posture, and cited as evidence the receding heel bones and the elongated pelvis.

2. Great Chain of Being and the "Missing Link."—A basic concept that constituted the organizing assumption of primate taxonomy, from its inception to well after the formal appearance of a theory of evolution in 1859, is the idea of the "great chain of being" or the hierarchical arrangement of nature. This great explanatory theory made necessary a correlative concept, that of the famous "missing link." The missing link proved to be of less value to scientists than to P. T. Barnum, who entertained the public with specimens of every conceivable link between groups of animals, including for good measure a mermaid. One useful result of this belief in unilinear gradation was the search for previously unknown forms which would complete man's knowledge of the chain of being. With this inclusive charter, the scientists of western Europe were ordained to take an inventory of nature and to determine the appropriate place of each newly described form. In practice, it of course supplied the theory for understanding not only man's place in nature but that of all other organisms and was extended to cultures as well. In the absence of genetics and a concept of culture, personality traits as well as skin colour were used for classification. The period between Tyson and the later study by Thomas Huxley, *Man's Place in Nature* (1863), is filled with works devoted to the positioning of the anthropoid apes, monkeys and newly discovered "races." While some persons investigated the anthropoids others were impressed with the possibility that various groups of unknown aborigines might be the missing link or links. Thus, the "savage Hottentot" or the "stupid native of Nova Zembla" (Novaya Zemlya) was pressed into service to fill the gap between anthropoid apes and man. Two important misleading research practices came into being in this period and remained in effect long after the formal recognition of a theory of evolution as expressed by Charles Darwin, and even after the development of genetics in the 20th century. First is the habit of ranking existing human races in a hierarchical order, and second, the practice of comparing human races with the contemporary apes for purposes of ranking rather than for functional or behavioural equivalents. That both these practices pose real obstacles to contemporary research may be seen in a statement by S. L. Washburn.

> The practice of comparing individual races directly to the apes should be abandoned. It is usually done with the best intent to show that, although the White is more like the ape in one character, the Negro is in another. But what this practice actually does is to keep alive the idea that it is reasonable and scientifically defensible to compare living men with living apes for the purposes of arranging races in some hierarchical order. What meaning have these comparisons when the races have nearly all their ancestry in common? (S. L. Washburn, "Thinking About Race," Smithsonian *Report*, publication 3833, pp. 371–372 [1945].)

3. Darwin's Theory of Evolution.—Publication of *The Origin of Species* by Charles Darwin in 1859 provided the outstanding theoretical contribution of the 19th century. The essential concept for the evolution of man was that of natural selection, though many more decades were to pass before its implications were either appreciated or employed. Darwin not only showed that evolution took place in the different organisms but he also provided an explanation which was sound in its major outline and which subsequently was given more precise meaning. The idea that nature selects those forms which are better adapted to a particular geographic zone and way of life laid the basis for understanding the adaptive radiations of the primates. Anthropologists were slow to appreciate the implications of adaptation and continued to measure and to observe traits which were felt to be nonadaptive. Linnaean species, the hypothetical prototypes of which individual specimens were copies in varying degrees of perfection, continued to be described. The weight of attention remained on classification rather than on processes of evolution, and research continued to focus on description without a corresponding concern for understanding the functional significance of traits or the role they might play in the adaptation of a species to its ecological zone.

in the morphology of the skull. The discoverers of the first fossil remains were placed in the unenviable position of having to generalize and interpret on the basis of the smallest possible sample before a skeptical if not hostile scientific world.

One of the chance happenings which shaped much subsequent interpretation of fossil man was the discovery of Neanderthal man before the discovery of older forms of man. Neanderthal man became a kind of benchmark from which surveys of other fossil men were sighted. In addition the generally primitive character of Neanderthal man preadapted scientific minds to expect a corresponding uniformity of primitive characters in other finds. Thus, the idea of a modern femur associated with *Pithecanthropus* or of a modern pelvis with an apelike skull appeared incongruous or disharmonic.

In 1924 Raymond Dart discovered a portion of skull and cast of the inside of the skull of an immature apelike individual. The cave deposit from which it was removed was located at Taungs, Cape Province, S.Af. He applied the name *Australopithecus*, or southern ape, and this name is now used to designate the subfamily Australopithecinae into which the several subsequent and related finds are commonly grouped. The australopithecines, usually treated as a genus with two major subgeneric forms, *Australopithecus* and *Paranthropus*, are well known from five sites at three localities. The *Paranthropus* group is larger in body size and occurs somewhat later, possibly persisting into the early Middle Pleistocene period. The other appears to begin as early as the Pleistocene-Pliocene boundary approximately 1,000,000 years ago. Simple stone tools have been found which suggest that the australopithecines were actually tool-making and tool-using animals. Another form similar to *Paranthropus* was found at Olduvai gorge, Tanganyika, Tanzania, in 1959 by L. S. B. Leakey and named *Zinjanthropus boisei*. The massive skull appears to have been well balanced in spite of exceptionally large teeth. A sagittal crest of bone provided additional area for the temporalis muscle. His diet included rodents, birds, snakes and immature large animals. Pebble tools of the Oldowan, pre-Chelles-Acheul, culture are said to testify to his human status.

The combination of characters in these forms demonstrates quite neatly the different inferences which may be drawn depending on the evaluative premises employed. The brain is comparable in size to that of the modern large apes, about 600 c.c., but as their body size is smaller the brains are relatively larger than in contemporary apes. The face protrudes but in many specimens the muscular ridges are not as prominent as in modern apes. The forehead is much more rounded and there is not the continuous bar of bone across the brows. The spinal cord enters the base of the skull at a point further forward than in modern apes. This indicates a better balanced skull, commonly associated with erect posture, though not as well balanced as in modern man. Flat crowns indicate that the teeth were worn down by the rotary movement characteristic of human mastication. The canine teeth, ordinarily large in the great apes, are not as robust in the Australopithecinae. The hipbone is of essentially modern human type and bears clear evidence that these beings stood and walked erect. This combination of characters demonstrates that the evolution of the lower limbs preceded that of the brain. The same precedence of limb development preceding brain expansion has been noted in some Eocene lemurs. The Australopithecinae clearly are well-qualified candidates for the position of human being. If their lagging brain size is emphasized, then they constitute the most manlike apes known. If the bipedal complex, the pelvis, lower limbs, skull structure and dental anatomy are emphasized, then they constitute one of the most apelike forms of man. Special mention should be made of the diversity within this subfamily. *Paranthropus crassidens* presents one of the largest mandibles found and a cranial capacity that may be as much as 980 c.c. It is possible that the final studies will indicate cranial capacities well in excess of those of the apes. If the Australopithecinae are too late to be an ancestral population of modern man, they nevertheless remain models of the kind of adaptive radiation specialized for walking which led to man.

The Australopithecinae illustrate the notable fact that different parts of the body evolved at different rates. These forms had entered a completely different adaptive zone with erect posture. Selective pressure was apparently directed toward the locomotor complex, and the other characters of the body necessarily lagged behind. The idea of a missing link which would be halfway between man and the apes is clearly illusory. Such a generalized ancestor is an unnecessary postulate. Ancestral forms must be specialized for a particular time and place and this means a morphological commitment to a means of locomotion prior to the later elaboration of the brain. (*See* also AUSTRALOPITHECINE.)

2. Java and North China Finds.—The first indubitable remains of man are those of the pithecanthropoid and sinanthropoid groups of Java and north China. Geological evidence places them in the Middle Pleistocene. ***Pithecanthropus erectus***, first discovered by Eugène Dubois in 1891–92, is known from the further finds of G. H. R. von Koenigswald. *Pithecanthropus* possessed a cranial capacity of about 900 c.c. The first, and the succeeding skulls, are characterized by a large, continuous brow ridge, a low vault with sloping forehead, thick bones and a heavy reinforcement system in general. One unusually massive skull, *Pithecanthropus robustus*, skull iv, found in 1939, displays an interesting keel-like ridge running over the top of the skull. As with the others the greatest breadth is at the base of the skull rather than above the level of the ears as in modern man. *Homo modjokertensis*, belonging to the Lower Pleistocene, is a baby *Pithecanthropus*, possibly of the robust type.

The possibility of giant forms preceding *Pithecanthropus* could not be judiciously dealt with until more evidence became available. A massive lower jaw fragment, *Meganthropus palaeojavanicus*, was found by Von Koenigswald. This and the finds of three enormous molar teeth of *Gigantopithecus blacki* and a mandible have been construed as possible giant forms of early man preceding *Pithecanthropus*. A similarity to African australopithecines has also been noted. Additional evidence must be presented before a reliable hypothesis can be constructed.

Of the long list of comparable characters in *Sinanthropus* the most noteworthy is the greater average cranial capacity of 1,04[illegible] c.c. This is a significant advance over *Pithecanthropus*, who average 860 c.c. for three skulls. The total range of both the Javanese and the Chinese capacities is from 775 c.c. in one of the Javanese skulls to 1,300 c.c. in one of the Chinese skulls. This is a high degree of variability and constitutes one of the reminders that fossil men were no less variable than modern men. Considerable prognathism or forward protrusion of the jaws is characteristic of these forms. At the same time, the limb bones indicate that the erect posture and gait of modern man had been achieved though the stature was short. Both these groups can easily be accommodated within one taxonomic category such as *Pithecanthropus*. Two Middle Pleistocene mandibles (*Atlanthropus*) associated with handaxes, from Ternifine, Algeria, may also belong in the *Pithecanthropus* group

The next major collection of human crania in Asia is that of Solo man from Java. The presence of 11 skulls gives a rather fair idea of the range and variability in this group of Upper Pleistocene man. Unfortunately, none of the faces are present and there is evidence that the skull bases have been artificially removed, possibly an evidence of cannibalism. If so, a rather generous meal was provided, for the cranial capacities of these men range from 1,150 to 1,300 c.c. The bony reinforcement system has begun to disintegrate, though the vaults are low with long sloping foreheads. They have the distinction of being among the longest human skulls of either fossil or modern man. Solo man is considered by some as an Asiatic representative of the Neanderthal race of Europe. The Saldanha and Rhodesian skulls of Africa may similarly be considered variants of the Neanderthal race. Another single but clearly ancient skull is that of Mapa, Kwangtung province, south China, found in 1958. It is Middle Pleistocene in age and may help fill the gap between *Sinanthropus* and Solo. Other fossil finds such as those of two large skulls from Wadjak, Java, and the Keilor skull of Australia have been used to construct a lineage for the modern Australian aborigines, leading back through Solo man to *Pithecanthropus*.

3. Neanderthal Man.—The Neanderthal fossil remains fall [illegible] early or progressive. They differ in morphology, [illegible] to the fourth glaciation and has been found in Europe associated [illegible] is characterized by a heavy, bi arched shelf [illegible] low, retreating forehead [illegible] without the hollow area [illegible] man; large orbits; small cheekbones, large palate and teeth, receding chin, and rounded angles where the horizontal body of the jaw meets the vertical body. The cranial capacity is remarkable [illegible] mately 100 c.c. above that of modern man. The skeleton is characterized by robust development except [illegible] curved bones of the leg and [illegible] ones of modern man; a round barrel chest; large hands and feet; large condyles at the ends of the long bones; long [illegible] vertebrae to [illegible]

In contrast to this classic form is the early or [illegible] which for the most part is third interglacial in time and is more modern in appearance. The frontal brow ridges are divided into three parts, the vault is higher, the face is shorter [illegible] steeper and higher, the cheekbones are more strongly developed, the bones of the skull are lighter and [illegible] shorter and the skull is better balanced, and there [illegible] complexes will indicate the interdependence of [illegible] characters. The weak development of the [illegible] portion of the orbit, the weak development of the cheekbone and also the corner of the mandible [illegible] facial complex possibly related to a small masseter muscle.

One result of the large number of [illegible] fundamentally different kinds is [illegible] guishing modern man from [illegible] skeletal population from Mt. [illegible] that combine varying degrees of Neanderthal with modern traits. [illegible] a population can be interpreted as hybrid, intermediate or [illegible] found in Mousterian deposits of only 43,000 years ago at Shanidar, [illegible] there is not an inexorable sequence in [illegible] continuously from primitive to modern.

4. Modern Man.—Modern forms of man are [illegible] Pleistocene remains [illegible] for investigation. Unfortunately the conte[illegible] England [illegible] more tha[illegible] usual [illegible] Fontéchevade [illegible] graphic [illegible] resemblances to modern man.

[illegible] of modern man [illegible] remains were found. [illegible] an old man, [illegible] Europe, a M[illegible] It is highly improbable [illegible] there. This is a [illegible] found inside a [illegible] a race.

The principal trends in the transformation of the [illegible] of early man into that of modern man may be summarized in [illegible] descriptive points. It [illegible] of what has happened to various characters and does not separate out those traits which are independent from those that belong to the same functional complex: (1) the brain case has increased in size and the face has been correspondingly reduced; (2) the forehead rose; (3) the face and jaws withdrew; (4) the skull increased its height further back behind the coronal suture, thus creating the "hominid hump"; (5) the area where the neck muscles attach at the back of the skull moved down and the condyles on which [illegible] such as the greater efficiency in balancing a more globular head, could not be determined on the basis of information available in the early 1960s.

5. Generic Relationships of Fossil Men.—It is probable that [illegible] species ever existed at one time. The scien[illegible] generic relationships. There is no evidence that any groups of fossil man were incapable of exchanging genes, and there is considerable evidence in the morphology that the course of human evolution was reticulate with many interchanges between contiguous populations. Man speciated only once—when he branched [illegible] stock. The history of fossil man reveals the development of many local or geographic races. There has been no development of genuine species, however, in the sense that a discontinuity, resulting from reproductive isolation either in time or space, has ever occurred.

II. The Rationale of Race Formation and Classification

Accompanying the realization that a race is essentially an epi[illegible] of race is comparatively simple; calculation of the effects of some of the processes of race formation is quite [illegible]

1. Breeding Populations.—Although [illegible]

distinctive in the high frequency of the blood factor Rh negative and group O. The term "continental race" for the major continental groups and "local race" for the component populations has also come into general use.

The outlines of a breeding population are delimited by cultural factors in most cases. Those people speaking a common language and sharing a common cultural heritage naturally mate with each other, at least more frequently than they do with people of another culture area. The castes of India provide a splendid example of the cultural compartments which reduce the exchange of genes. The Eskimo and Indians of North America contact each other in part of their geographic distribution, yet they seldom mate with each other. They are separated by mutually unintelligible languages and by cultures which have different value systems. The Pygmies of Africa and the adjoining Bantu Negroes speak the same language but have different economies and social organizations. Geographical features may also separate populations, as the Sahara desert which separates Negro Africa from northern Africa, the latter being occupied by members of the Mediterranean race. The task of distinguishing the outlines of a breeding area is essentially ethnological; such an area is defined by noting who marries whom and not by the physical traits which are shared by the resulting population. The close relation between the distribution of culturally defined groups, whether by language, economy or some other aspect of culture, and the distribution of races has led some persons to infer a causal relationship between race and culture. There are no biologically inherited cultural features as such and the relationship is purely one of correlation or historical association. As a particular culture enhances the interaction between its members and reduces the interaction with outsiders a breeding group is defined. In the event of social stratification or of geographic dispersion, breeding isolates within the over-all population come into being. Growth studies and racial anthropometry have demonstrated that upper classes, classified as upper either in terms of social or economic criteria, are invariably taller than the lower strata of the same society. Geographic differences occur similarly within over-all breeding populations, as, for example, the Aleut-Eskimo population or stock. Eastern Eskimos of Greenland are significantly different in some characters from the western Eskimos of Alaska; and the eastern Aleuts are significantly different in a few characters from the western Aleuts.

2. Single Species.—Although cultures serve to maintain group differences it should be noted that one of the over-all effects of human culture is the maintenance of a single species. Darwin observed that races are incipient species. Interestingly, in human beings these subdivisions of the one species have always remained as subdivisions and have never differentiated into separate species. Man is able to successfully occupy all the known ecological niches that are accessible to such a creature and thus he cannot speciate. He is able to occupy these diverse zones largely as a result of his culture, which in each place enables a specific adaptation, such as the ability to make tailored clothing in the Arctic. Man has thus specialized in despecialization.

3. Phenotype and Genotype.—Races represent combinations of discrete traits. The visible manifestations of traits are referred to as the phenotype; the genetic constitution of an individual is known as the genotype. Individuals inherit the genes or capacities for traits in their germ plasm. Each person receives 23 chromosomes from each of his parents. Each of these chromosomes contains or is composed of several hundred genes. Mendel demonstrated that traits are not fused in inheritance but remain distinct and segregate out in various ratios. Mendel's law of segregation is also the basis for the concept of genetic equilibrium which illustrates the way in which traits remain in a population whether they are dominant or recessive. Thus, brown-eyed parents may have a child with blue eyes if they each carried a gene for blue eyes. The old blood theory of inheritance is clearly invalid. It implied that a population with members mixing at random would, in time, become uniform. This rested on the false assumption that the variability would decline with each generation because children of the same parents must inherit the same traits. It is, in fact, possible to determine the genotype of parents by seeing the traits which appear in their children. Thus, two parents of blood types A and B may have a child of blood type O. It is obvious then that each of the parents also had a gene for blood type O (not detected by conventional tests) and that the child received the genes for type O rather than for A or B. When the number of genes responsible for phenotypic traits is known, as in the case of the blood groups, it is possible to compare races on the frequencies of those genes. The gene frequency method of describing races is one of the major accomplishments in race studies. A racial classification based on gene frequencies has been formulated by W. C. Boyd:

1. Early European group (hypothetical). Possessing the highest incidence (over 30%) of Rh negative type (gene frequency *rh* 0.6) and probably no group B. A relatively high incidence of the gene Rh_1 and A_2. Gene *N* possibly somewhat higher than in present-day Europeans. Represented by their modern descendants, the Basques.
2. European (Caucasoid) group. Possessing the next highest incidence of *rh* (the Rh negative gene) and relatively high incidence of the genes Rh_1 and A_2, with moderate frequencies of other blood-group genes. "Normal" frequencies of M and N; *i.e.*, M = *c.* 30%, MN = *c.* 49%, N = *c.* 21%. (The italicized symbols stand for the genes, as opposed to the groups.)
3. African (Negroid) group. Possessing a tremendously high incidence of the gene Rh^0, a moderate frequency of *rh*, relatively high incidence of genes A_2 and the rare intermediate *A* (A_1, A_2, etc.) and Rh genes, rather high incidence of gene *B*. Probably normal M and N.
4. Asiatic (Mongoloid) group. Possessing high frequencies of genes A_1 and *B*, and the highest known incidence of the rare gene Rh^z, but little, if any, of the genes A_2 and *rh* (the Rh negative gene). Normal M and N. (It is possible that the inhabitants of India will prove to belong to an Asiatic subrace, or even a separate race, serologically, but information is still lacking.)
5. American Indian group. Possessing varying (sometimes high, sometimes zero) incidence of gene A_1, no A_2 and probably no *B* or *rh*; high incidence of gene *M*. Possessing Rh^z.
6. Australoid group. Possessing high incidence of gene A_1, no A_2, no *rh*, high incidence of gene *N* (and consequently a low incidence of gene *M*). Possessing Rh^z.

One of the most important antigens for which sufficient population studies have been made to permit generalization is the Diego factor. It is found in highest frequency in South American Indians, in varying frequency in other American Indians, and in Asiatic Mongoloids. It is not found in Negroes, Europeans, Oceanic peoples nor, oddly, in Eskimos.

Abnormal hemoglobins, haptoglobins and other biochemical traits show great variations between populations. The sickle-cell trait (Hemoglobin S) is found in highest frequency in east Africa, less in west Africa, India and about the Mediterranean. It confers an advantage to the possessor of one gene (thus a heterozygous individual) in resisting the effects of malaria. Persons with two genes (homozygous) are more likely to die of anemia early in life, and those with no gene have least resistance to malaria. In this case, and probably in many more, selection favors the heterozygous individuals, who would not exist without maintenance of the other two genotypes. For particular environmental stresses evolution must proceed with the production of "unfit" individuals in order to produce the more "fit."

It should be kept clearly in mind that a blood type is a phenotypic trait, even though it is under the skin. It happens that the number of genes responsible for the blood groups can be accurately inferred. Human races can be differentiated by using the percentage of the blood types, rather than the gene frequencies, in precisely the same way that the percentage of black hair or blue eyes may be used to differentiate populations. It is still common practice to cite the percentage differences in the Rh types. Thus, the early racial classifications which cited the varying percentages of hair colour or eye colour, etc., were adequate in many respects. However, much greater precision, especially in calculating the effects of selection of mixture, is possible when the exact number of genes is known. By using the frequencies of genes in various populations it is possible to find gradients or places where the frequencies change quickly. Thus, the problem of intergradation between populations may be dealt with.

Where the frequency of one kind of gene will not distinguish between two races, other unrelated genes will do so. Egyptians are similar to Micronesians in the frequencies of the three genes

responsible for the ABO blood groups, yet they are different in the frequency of the Rh genes. This simply points up the fact that a number of criteria must be used for differentiating races. Chance similarities are not likely to occur in many different systems of unrelated traits.

It must be noted that the constituent elements of races are discrete traits and not genotypes or types. A single population contains within it many different combinations, each of which may be called a type. There is no gene for a type. Any combination of traits may occur, and the likelihood of occurrence is dependent solely on the number of constituent genes in the population. We may note that an individual is of blood type AB or of the Nordic morphological type. These are not units of inheritance and cannot be treated in the same way. The combination of blue eyes, light brown hair, long head and tall, linear body is a chance combination depending on the frequency of the individual characters in the population for its appearance. There is no inheritance of a Nordic type and children of the same parents may belong to quite different types. In the same way a child does not inherit its genotype as such but inherits the genes, from both parents, which then compose its genotype.

The idea of racial types is essentially pre-Darwinian. It implies original or ideal forms which became mixed or from which many individuals deviated. Actually, the fossil record provides ample evidence that populations have always been characterized by variability in many traits; no ancestral types have ever appeared. A concept related to type is that of a "primary" race. A necessary corollary is the idea of secondary races which presumably arose from the primary ones, with tertiary and quaternary races logically following. From the standpoint of population genetics such postulates are superfluous.

The basic concept of gene equilibrium explains how genes behave in a population which is not in a process of change; *i.e.,* not undergoing evolution. Recessive and dominant genes will be maintained in the same proportion with which the population started; in other words, the variability of the population will be indefinitely perpetuated from one generation to the next. This assumes random mating and equal survival of all kinds of offspring. Assuming that eye colour is controlled by a single pair of genes, one for brown eyes, which are dominant, and one for blue eyes, which are recessive, those children who receive a gene for brown eyes, indicated here by A, from one parent and a gene for blue eyes, indicated here by a, from the other parent, will have brown eyes since brown is dominant. This may be placed in the Hardy-Weinberg formula by letting q stand for the sex cells with gene A, and $(1\text{-}q)$ for the sex cells with gene a. This formula illustrates the way in which the frequencies of q and $(1\text{-}q)$ remain constant generation after generation and in which the proportions of persons with brown and blue eyes then remains the same:

$$q^2AA \text{ (brown eyes)} : 2q(1\text{-}q)\ Aa \text{ (brown eyes)} : (1\text{-}q)^2aa \text{ (blue eyes)}$$

There are four major processes which alter gene frequencies: mutation, genetic drift, selection and hybridization. A mutation is a sudden change in the genetic materials, and thus mutations are the raw materials of evolution. A new mutation, such as a new Rh factor in the blood, may be increased in frequency by selection, or it may be lost. Random genetic drift, the Sewall Wright effect, refers to the chance loss of genes in a small population. A small migrant group may branch off a larger group and by chance have no individuals with a particular gene. Or such a small isolate might have only a few carriers of the gene and by chance none of those genes would be passed on to succeeding generations. It is likely that blood group B was lost by the small isolated group of Arctic Eskimo of north Greenland. The great variability of the American Indians in their blood groups may possibly be the result of the operation of genetic drift. Primitive peoples who live in small groups with uncertain economic foundations are more likely to display chance fluctuations in gene frequencies than are large and stable populations. Genetic drift may have been of much more importance in the past when most of the world's populations lived in small, isolated groups. Selection, best defined as differential fertility, is the favouring of certain genes whereby their frequency is increased. With even a very slight selective advantage gene frequencies may be considerably altered. Though selection is often considered as a screening agency which removes deleterious genes it may equally well be considered a creative force as it provides direction by favouring or disfavouring certain genes. The general increase of roundheads in Europe may be an example of selection operating in favour of better balanced heads, though this hypothesis could not, as of the early 1960s, be demonstrated. The long-term tendency for heads to become more globular, as noted in the review of cranial transformation, may provide evidence for this speculation. Hybridization is one of the most common ways in which gene frequencies are altered, though this may not have always been the case. Race mixture obliterates the differences between the participating groups and enhances the differences between individuals within the new hybrid population.

Adaptation in traits whose mode of inheritance is not yet known is as important for the survival of populations as for the single gene traits. Comparative racial physiology has accumulated much valuable data on body size, tissue distribution, pigmentation, nutrition and climate. True physiological adaptation to cold climate has been found among the central Australian aborigines. They permit greater body cooling without metabolic compensation, while sleeping in the cold, than do other peoples tested.

Human races are constantly changing, though at different rates, and the boundaries are constantly shifting. Natural selection continues to operate; *i.e.,* there is differential survival of different genotypes. It is quite likely that natural selection favours the maintenance of a range of mental capacities in all different races. There is clearly the need for considerable innovative ability on the part of any society in the world. Selection for educability places a premium upon diversity of individuals as well as cultures.

Many of the traits commonly used for racial classification such as stature, pigmentation, cephalic index, are expressions of several interacting genes, each one contributing only a small effect. These polygenic traits vary continuously and as a consequence have been described in terms of averages or arithmetic means with certain measures of dispersion. Certain limitations are imposed by the use of these kinds of traits in that phenotypically similar individuals and populations may not be genotypically similar. Another disadvantage is that they cannot be manipulated as conveniently for analysis. Thus, we cannot predict how tall a hybrid population will be which is the result of crossing a population with a mean stature of 168 cm. (66.14 in.) with a population averaging 161 cm. (63.39 in.).

The degree of morphological similarity between groups is an adequate measure, when sufficient numbers of traits are used, of the degree of actual genetic relatedness. Various coefficients of divergence can be used for comparing three or more groups. If only a few features are used the results may be misleading. It is not, for example, possible to establish the relationship of Oceanic Negroids of Melanesia to the Negroes of Africa even though they bear a number of phenotypic similarities. The Bushmen of south Africa were formerly thought to show traces of Mongoloid parentage on the bases of their yellowish skin colour, broad cheekbones and eyelid fold covering the inner corner of the eyes. However, there is nothing in the blood group systems which confirms such a parentage nor is there any skeletal evidence that would support such a view.

There is a substantial correlation between the gene-frequency method and the morphological method of evaluating the biological differences between populations. This is to be expected inasmuch as these are two methods of describing a population which is defined by independent ethnological criteria; *e.g.,* mating patterns laid down by the culture. Such a study has been done for five caste groups of India (L. D. Sanghvi, 1953). In studying the causes and processes of race formation the interpretation of human evolution in the remote past becomes infinitely more meaningful.

III. APPLIED ANTHROPOLOGY

The term applied anthropology (and its forerunner "practical anthropology") came into use between the late 1920s and middle 1930s. It indicated, and in a sense proclaimed, the new interest of social (or cultural) anthropologists in research meant to give practical aid and guidance to governments and other bodies controlling public life. It should be emphasized that the term marked off an area of interest rather than a separate branch of social anthropology. Many anthropologists worked in both fields. Nor was there any difference in the methods employed; even in its applied form anthropology involved the systematic study, at first hand, of societies as yet unknown or inadequately known. The difference lay in the scope of the research, which, in applied studies, centered upon problems of practical importance, and in the commitment of the research worker, who expected to place his skill and knowledge at the disposal of the nonscientist and "practical man."

Applied anthropology thus came to mean essentially employed anthropology, if the term is understood sufficiently widely to include, besides salaried employment, also the mere encouragement and sponsorship of particular investigations. Since the anthropologist studied primarily "primitive" and exotic peoples, it was natural that his researches should be of special interest to colonial governments and that these should have become his principal employers. Though this took time and was not accomplished without considerable pleading on the part of leading anthropologists such as Bronislaw Malinowski, A. R. Radcliffe-Brown and C. G. Seligman, the case for applied anthropology definitely seemed to be convincing.

1. The Need for Applied Anthropology.—In our own society the men entrusted with public affairs are, as a matter of course, familiar with the general social situation and ready to rely on such disciplines as history, economics or political science for the solution of more specialized problems. It seemed common sense to expect colonial administrators to possess a similar knowledge of the peoples and problems they were dealing with, and to rely on anthropology as the scientific discipline providing it. Nor would this knowledge prove less useful to others—missionaries, educators, doctors and the like—working among "primitive" and exotic peoples.

Many examples could be quoted of political measures failing in their purpose, or even leading to disastrous results, because they were taken in ignorance of native custom and the factors underlying it. The Ashanti War of 1900 is a classical case. It was provoked by the ill-advised demand of the British governor for the surrender of the golden stool of the tribe, which he took to be a symbol of sovereignty while in reality it was a sacred relic, not to be exposed to profane eyes. Other misunderstandings had less spectacular though still serious effects, such as the efforts of administrators and missionaries to suppress the African custom of bride wealth, paid by a man for his future wife, on the grounds that it reduced women to mere chattels, or the attempt of the Canadian government to abolish the potlatch feasts of the northwest American Indians, in which it saw merely a wasteful, wanton destruction of property.

The anthropologist could have shown that the bride wealth corresponded, in these societies, to a contract of marriage and, far from lowering the dignity of women, gave them full legal status; and that the "wastefulness" of the potlatch enabled men to achieve prestige and display social prominence. Above all, the anthropologist could have predicted that the disregard of customs playing so crucial a part was bound to disrupt the native society and undermine its morale. If the understanding of the indigenous way of life could have prevented the more disastrous consequences, it would also have helped to dispel many of the popular prejudices about native races—that they are "by nature" lazy, dishonest, improvident, mentally backward, or hopelessly conservative.

The helpfulness of anthropology must not, however, be exaggerated. The discovery of the true significance of a custom did not necessarily dispose of the difficulties of government created by it. In coping with these the administrator had to claim a free hand, even to the extent of radically interfering with tradition. And clearly, no modern, humanitarian government could permit the continuance of tribal wars or blood feuds, countenance practices endangering human life or recognize sorcery and witchcraft. But there were other factors also. Even native ways of life wholly justifiable and inoffensive were sacrificed when they conflicted with "higher policy": indigenous land titles were overruled by a policy encouraging white settlement; the disruption of community life counted for less than the need of recruiting able-bodied men for labour or service in colonial armies.

Even so, anthropological information was not reduced to futility. At the least, it enabled the administrator to calculate the consequences of his actions; often, it would suggest to him the best course in the circumstances—a policy of judicious transition, a workable compromise or safeguards of some kind. For example, the anthropological study of labour migration in Bechuanaland, carried out by the South African anthropologist I. Schapera, established that its most disruptive effects were the result, not of the numbers of migrants, but of their prolonged absence from home, and that in the case of young men, especially those better educated, migration even proved to be a beneficial influence. These were clearly findings which opened the way for a useful policy of compromise.

2. Division of Responsibility.—All this indicated a division of responsibility whereby the anthropologist was to provide the relevant information while its actual utilization, its application in the strict sense of the word, lay with the administrator. It did not seem feasible to advocate a fuller merging of the two roles by giving the anthropologist administrative powers or turning the administrator into a professional anthropologist.

The qualities required of the good anthropologist did not necessarily make a successful administrator; only in exceptional cases would the same individual possess both or, for that matter, find it easy to reconcile the divergent viewpoints of the scientific student

of society and the man responsible for efficient government. Furthermore, once the anthropologist was identified with the regime he risked losing the vantage point of the impartial observer—the chance of winning the confidence of the people he studied or that of gaining an unbiased picture of their lives and interests. Finally, it became increasingly difficult to combine competent anthropological work with other professional duties. Though the semiprofessional, part-time anthropologist had in the past made valuable contributions to ethnographic knowledge, his work fell seriously short of the more exacting standards of modern research.

But some familiarity with anthropological thought and methods could only be of profit to the administrator, and similarly to the missionary or educator. The first steps in this direction were taken in Belgium, France and the Netherlands, where the normal training of colonial officials for many years included instruction in indigenous languages and cultures, offered at universities and similar institutions (such as the Université coloniale in Brussels and the École coloniale in Paris). In Great Britain studies of this kind were optional until 1946, when social anthropology was made a regular subject in the training courses for colonial officials (given at Oxford, Cambridge and London universities). Allowing for somewhat different interests, the U.S. Foreign Service institute in Washington, D.C., founded in 1947 for the training of foreign service personnel, similarly included cultural anthropology among the subjects taught.

It was not the object of this instruction, which was mostly on an elementary level, to produce competent research workers; it served its purpose best in teaching the future administrator to look at certain problems with the anthropologist's eyes and to recognize where anthropological investigations were needed. In this sense his training corresponded, as Melville J. Herskovits pointed out, to an "indirect" form of applied anthropology.

A. The Growth of Applied Anthropology

1. Early Beginnings.—Even before World War I colonial governments, especially the British, Dutch and German, in various ways encouraged anthropological investigations in their territories. In most cases no sharp distinction was drawn between studies by professional anthropologists and the amateur observations of officials, missionaries or explorers; but there were also significant exceptions, such as the expeditions, sponsored by the respective governments, of R. Thurnwald to German New Guinea (1912–14) and of C. G. and Brenda Seligman to the pagan tribes of the Anglo-Egyptian Sudan (1909 and 1911). In the United States the Bureau of American Ethnology, founded as early as 1879 for the study of the Indian tribes, at least laid the foundations for applied anthropological research, though this was slow in coming. There was little development until 1933 when John Collier, a keen supporter of anthropology, was appointed as commissioner of Indian affairs.

Generally speaking, applied anthropology began to come into its own between 1920 and 1930. It was then that several British colonies and dominions seconded political officers for anthropological work or appointed special government anthropologists, among whom were R. S. Rattray (in the Gold Coast—now Ghana), P. A. Talbot and C. K. Meek (in Nigeria), J. H. Hutton (in India), F. E. Williams and E. W. Chinnery (in Papua and New Guinea). In 1926 the foundation of the International Institute of African Languages and Cultures (later renamed International African institute) marked a further important advance. Its five-year plan of research, inaugurated in 1932, was explicitly intended to "bring scientific knowledge and political affairs into closer association" and to provide "a scientific basis for dealing with the practical questions of administration and education." The following years saw a great deal of applied research, mainly in British African territories, as well as, in 1938, the setting up of the first research centre located in colonial Africa, the Rhodes-Livingstone institute in Northern Rhodesia.

The concentration of research in British Africa was no accident. For there the policy of indirect rule, envisaging the government of native peoples through their own leaders and political institutions, made accurate knowledge of their societies a prerequisite of political planning. Furthermore, the native peoples of Africa had been exposed to far-reaching contacts with western civilization, which were rapidly changing their way of life; the need to assess and guide the changes thus added to the problems requiring anthropological study. This latter reason held, of course, also for territories outside Africa; in consequence, research in applied anthropology tended to be increasingly focused upon, and in fact identified with, studies of culture contact and change.

2. World War II.—Though World War II temporarily interrupted most studies of this kind, anthropology also found a place in the wartime organization of the allied countries. Several anthropologists were attached to government departments or appointed to advisory committees; others, who had joined the services, were assigned to special duties requiring their particular skills and expert knowledge. Their duties were in the main concerned with military government in conquered or liberated territories, with intelligence work and with the planning of psychological warfare. Thus, in the British military administration of Italian east and north Africa anthropologists were given charge of native affairs. A team of anthropologists joined the Australian military government of New Guinea. In the United States, anthropologists taught at civil-affairs training schools, served in the military government set up by the navy in Micronesia or worked for the Office of Strategic Services.

The U.S. wartime researches extended far beyond colonial or primitive peoples. A team of anthropologists worked in the relocation centres set up for Japanese, both of U.S. citizenship and aliens; others, including Ruth Benedict and John Embree, undertook studies of the "national character" and morale of enemy countries, especially of Japan. In the latter studies the conventional anthropological approach, through the direct observation of a people in its environment, was of necessity replaced by the use of published sources, historical or contemporary, and by interviews with individuals exiled from their countries; also, parallel investigations were carried out by psychologists and psychiatrists, so that the contribution expected of the anthropologist consisted in his viewpoint, in his manner of interpreting the data, rather than in any particular research technique.

3. Developments After World War II.—After the war, applied anthropology expanded widely and rapidly. In Great Britain, where the program of colonial development offered a wide scope for applied research, the Colonial Social Science Research council, set up in 1944, commissioned numerous anthropological investigations in Africa, the West Indies, Borneo and elsewhere; the colonial office appointed anthropologists as consultants and established research centres in the new colonial university colleges in Uganda, Nigeria and the Gold Coast. In Australia the School of Pacific Administration, itself a postwar creation, had anthropologists on its staff and anthropology in its syllabus. In South Africa, the department of native affairs employed a team of anthropologists. India and Malaya were beginning to utilize anthropological research in the solution of their political and social problems. The government of French Equatorial Africa created a Commission d'Études Sociologiques, other French territories taking similar steps. International bodies like the Trusteeship council of the United Nations, the United Nations Educational, Scientific and Cultural organization and the South Pacific commission appointed anthropologists to their research divisions and on occasion sponsored investigations in the field.

In the United States, government agencies and private research foundations alike were keenly interested in applied anthropological work, which found a place in the administration of the U.S. trust territories and in several of the postwar projects of technical assistance to backward countries, especially in southeast Asia and the middle east. One American university, Cornell (Ithaca, N.Y.), specialized in the training of applied anthropologists. The Society for Applied Anthropology, founded in 1941, aimed at encouraging and co-ordinating such research, and also published its own periodical (*Applied Anthropology*, renamed in 1949 *Human Organization*). Largely stimulated by the North American example, scholars and government agencies in the Philippines, in Mexico and South America began to think on similar lines, of anthropology

applied to the problems of economic and political development.

As social anthropologists in general had come to extend their researches to advanced cultures and western societies, so applied anthropology widened its scope in the same sense. Two new types of applied research may here be mentioned, though both were subject to considerable controversy. First, the combined anthropological and psychological studies started during the war, of national trends or "national character," were continued in various European countries under U.S. auspices and the leadership especially of Margaret Mead. Secondly, a group of U.S. anthropologists, headed by Eliot D. Chapple, turned their attention to the problems of social and human relations in industry, accepting contracts for research from private firms. Anthropologists in Great Britain were moving more cautiously in the same direction.

The interest in mental health, finally, which had developed strongly since the war, opened up a further field for the application of anthropological knowledge and techniques and for the collaboration between anthropologists, psychiatrists and those concerned with social welfare.

B. Scope of Research

Regarding the more conventional type of applied anthropology, among primitive or exotic societies, three main lines of research may be distinguished, though in practice they tended to overlap: (1) general ethnographic studies, meant to provide information about a certain society or group of societies in a region; (2) specialized investigations of particular practices or institutions; (3) predictive analyses, needed for policies of political reconstruction, economic development, etc.

The first kind of study was also the earliest, and hardly differed from the descriptive studies of ordinary or general social anthropology. Colonial governments simply desired to have full reports on the people they governed, on their customs and institutions, even in the absence of any definite plans for utilizing the information.

1. Political Organization and Land.—The specialized investigations were usually suggested by some difficulty or weakness of administration. One such difficulty, widely encountered, concerned the location of effective authority. Chiefs and other political functionaries appointed by the government often proved ineffectual, either because the men in question were without traditional authority or because the latter was much more rigidly circumscribed than were the powers thrust upon these men under modern conditions. Sometimes no centralized authority existed at all which could provide the kind of leadership governments wished to see established. The religious sanctions behind chieftainship posed a special problem; for they might both buttress the secular office and restrict the freedom of action necessary for its efficient performance, as when a chief also had priestly functions or was invested with semidivinity. The investigation of indigenous political systems in consequence became one of the recurrent subjects of applied anthropological research.

Other problems demanding continuous research were land and land tenure. A great deal of research was devoted to the customary law of indigenous societies, so that it might be utilized or at least reckoned with by the government of the country. The principles of land tenure in turn had to furnish the legal basis for land litigation, for any registration of land titles and for land policy at large. Here the anthropologist could show that the modern concept of individual property, implying the right of free disposal by the owner, was largely inapplicable to primitive societies. Nor was land communally owned as many administrators thought. Rather, individual usufruct was combined with corporate titles giving kin groups or communities reversionary rights or rights of disposal. Religious factors again entered since land was often bound up with the worship of ancestors or otherwise associated with supernatural conceptions.

2. Culture Contact and Planned Change.—There were, further, the many instances of culture contact—the impact, upon primitive societies, of western technology and economy, of Christianity and western moral standards, and of other factors equally alien. The lesson that emerged most clearly was that their effects were rarely localized but tended to spread widely through the social fabric; wherever the change might start, ultimately it was likely to affect family structure, the relationship between the generations, group morality, even religious beliefs. It was chiefly these remote, and uncalculated, effects which gave culture contact its potentially disruptive character.

The lessons here learned had a direct bearing on policies of development and reconstruction. For whatever their specific objective—political reforms, economic advancement, education, health—they were essentially experiments in calculated social change. The anthropologist, by his analysis of the situation, had to provide the relevant social data needed for any reliable prediction of results. Often his responsibilities extended further, to giving advice on the most appropriate method of implementing a particular policy or even, if more rarely, on the wisdom of the policy itself.

This wider responsibility, however, placed the anthropologist in a genuine dilemma; for while it enabled him to act as a sympathetic intermediary between rulers and ruled, it also meant that his role was radically changed, ceasing to be that of the strictly scientific, disinterested student of society.

C. Results and Prospects

From the anthropologist's point of view the applied studies have in many ways been an undoubted gain. Concerned as they so often were with the effects of social change, they offered the nearest approach to the controlled experiment in the social sciences. The specialized inquiries greatly deepened our knowledge of particular aspects of primitive society and culture, especially of economic and political organization, land tenure and law. Scientific value apart, work in the applied field also offered to many anthropologists the purely human satisfaction of aiding backward peoples in their struggle to meet and master the forces of western civilization.

The concrete gains derived by colonial governments were more difficult to assess, partly because these were not bound to act upon the anthropological findings and partly because the value of the latter was not always wholeheartedly accepted. Sometimes, it is true, the anthropologist found himself embarrassed by the excessive confidence of his employers that he had the key to all problems. More often, they were inclined to question whether anthropology was in fact as helpful and the information it provided as indispensable as enthusiasts would make it out to be. Some impatience was felt with the "academic" anthropologist who would insist on comprehensive studies when only some specific information was asked for, or who seemed to deal in a complicated fashion, using complicated language, with issues which to the practical man appeared straightforward. To all this anthropologists could reply that, though the knowledge they stood for was not indispensable to government, it facilitated informed and smooth government.

But anthropologists also had to face another, more disturbing criticism—that they overemphasized the importance of tradition and were hostile to modern development. Nor was this view limited to colonial administrators; educated Africans and Indonesians openly expressed their distrust of a science whose primary interest was in "primitive" peoples and which might play into the hands of reactionaries and upholders of "colonialism."

If these objections did not promise too well for the future of applied anthropology, anthropologists themselves had grown more cautious. They came to fear that the applied work might entice too many of the younger anthropologists away from general and theoretical research, so that the very progress of the discipline might be endangered. Conversely, the man fully committed to applied work, like the permanent government anthropologist, would be in danger of losing touch with universities and academic centres, and hence with the advances achieved in his discipline. He would turn into a mere technician, perhaps still useful to his employers but no longer truly representing anthropological knowledge.

There were graver problems that were of an ethical nature. The change of roles forced upon the anthropologist when he is

consulted on the best way to implement government policies has been mentioned previously. To be sure, he might see no cause for disagreeing with the policy, and the best way of imposing it might well be understood to be the one best serving the interests of the native peoples. Even so, the anthropologist would abandon the standpoint of the scientist; he must pronounce upon the merits and demerits of particular courses of action, and thus introduce value judgments. Nor will the issues always be as clear-cut and uncontroversial, so that the anthropologist might have to take sides and argue from his own political and moral convictions. And if these had little chance against administrative considerations or the dictates of "higher policy," personal frustrations would be added to the dubiousness of his position.

Yet if the anthropologist presented his facts without adding recommendations or warnings, he would furnish information that might be put to uses with which he could not in good conscience agree. Or again, he might be tempted to restrict his advice to the most efficient means for achieving certain ends, dismissing the ends themselves, the policy to be implemented as not of his concern—which would hardly diminish his ethical commitment.

All these issues were widely and on occasion heatedly debated among U.S. and British anthropologists. In an attempt to clear the air the Society for Applied Anthropology published in 1951 a carefully worded *Code of Ethics*. It appealed to the social conscience of the individual research worker and to his responsibility at all times to uphold the moral tenets of our civilization—respect for the individual and for human rights, and the promotion of human and social well-being. Not all anthropologists were prepared to endorse this assumption of a moral mission on the part of the "disinterested" scientist. The dilemma, then, though vital for the future of applied anthropology, remained unresolved.

ANTHROPOLOGY AND ETHNOLOGY, SOCIETIES OF. In the 1960s there were about 350 anthropological societies in the world. These vary greatly in size of membership and in geographical breadth of interest. The vast majority of them are nongovernmental, devoted exclusively to anthropology or to a subdiscipline thereof, and have as their major purpose the exchange and dissemination of scientific information, notably via regular publications and meetings. Most of these societies, including the oldest ones still active, are found in the United States, in Europe and in former European dependencies in Asia, and in Japan. More recent societies have originated in Africa and in Oceania, predominantly at the instance of Europeans. In most of Latin America, anthropological societies are still small and with local purposes, and individuals of broader interests follow the activities of their national scientific bodies.

Nations throughout the world often have some sort of national scientific body wherein anthropology is one subject for attention or even the focus for a special "section." There exist, also, relevant national committees of anthropologists, national liaison societies composed of representatives from several other societies, intergovernmental organizations, international nongovernmental organizations, and international nongovernmental regional organizations with regional headquarters. Membership in many of these is institutional only, appointive, or otherwise restricted.

See *International Directory of Anthropological Institutions*, edited by William L. Thomas, Jr., and Anna M. Pikelis (1953). (A. M. P.; F. R. E.)

ANTHROPOMETRY, a term coined by the naturalist Georges Cuvier (1769–1832), means the measurement of man, and is derived from the Greek roots for "man" and "measurement." Long used by physical anthropologists for the comparison of man to other primates, and for the comparison of different racial groups, anthropometric measurements are now employed in a variety of disciplines. Anthropometry assists in the diagnosis of endocrine disorders, in the assessment of growth and development and in the evaluation of nutritional status. Anthropometric measurements are employed in the design of equipment, in the sizing of clothing, shoes and sunglasses, and in automotive and air-frame construction. In space travel, the techniques of anthropometry are necessary to assure man both comfort and protection.

The simplest anthropometric measurements, such as stature, are made with familiar equipment. By selecting reliable measuring points, or "landmarks," and standardizing the techniques, such static measurements can be made with great accuracy. Where these measurements are to be used as norms, or standards (as for height or weight), the primary problems are those of sampling. The sample used for comparison must be large enough to provide an idea of the total range of measurements, and it must be representative of the population the anthropometrist intends to describe.

Modern anthropometry, however, has gone beyond the limits of meter-sticks, calipers and tapes. Equipment now reads directly on counters or dials, can be adjusted for constant tension and can feed measurements directly to punch cards or computers. Some of the measuring devices are designed to determine the thickness of the fat layer beneath the skin, and others meter the percentage reflectance of the exposed or unexposed skin. Anthropometric measurements of bone, fat and muscle are made directly on X-ray films, and ultrasonics is used to determine the depth of fat and muscle in living human beings. Often, anthropometric measurements are made directly on photographs.

A variety of techniques have proved useful in measuring the component tissues of the body. Underwater weighing, using Archimedes' principle, yields the specific gravity of the human being. Dyes or trace substances injected into the blood indicate, by the extent of dilution, the size of the fat-free volume. Through measurements of the density of X-rays of the fingers, the mineral mass of the entire body can be estimated.

Anthropometric measurements can be summarized by averages or means, as for stature or weight. Frequently, proportions or ratios are used, as when relating limb length to body length, or comparing the length of the upper and lower limbs. In reporting data on body composition the amount of fat is usually expressed as a percentage of gross body weight. Thus in adults, those whose fat is less than 5% of total weight are lean, while those with over 25% fat are obese. Such quantitative information is more meaningful than expressions of underweight or overweight. There are fat underweight individuals and lean overweight individuals.

Stature, weight, percentage of fat and the reflectance of the skin are static measurements, and they are one- or two-dimensional at best. It is also possible to provide true three-dimensional anthropometric data, using the Cartesian system of co-ordinates. The field of "dynamic" anthropometry, moreover, measures man in motion, or the effective body size of an individual engaged in a particular task. For the volume of a seated man quietly engaged in reading a book, this effective body size is approximately 54 in. high, 30 in. wide and 36 in. deep. The living human being engaged in any particular occupation occupies a space-envelope far larger than his minimum corporeal dimensions. Thus, time-lapse photography has become an adjunct to direct anthropometry.

The design of ready-made clothing involves complicated uses of anthropometric data. Any system of sizes must be keyed to simple body measurements such as stature, chest girth and leg length. But for each combination of measurements used to define a size (such as 36-long) as many as one hundred supplementary

measurements must also be incorporated into the patterns or model-forms. Similar complexities relate to automobile seats, airplane cockpits and space capsules. Controls, levers and switches must be close enough to grasp or operate, but not so close as to invite accidental operation. In such applications, designs based on anthropometric measurements must be subjected to actual fitting tests. Such tests combined with anthropometric data help to eliminate driver or pilot error.

Anthropometry, as in Cuvier's time, is the measurement of man, but today it involves man in motion, three- or even four-dimensional measurements, apportioning of the tissue components of the human body, and measurements of strength, reaction time and fatigue. Man in space must be protected against heat, cold, radiation and acceleration (*g* force), yet his protective clothing must not become an encumbrance in itself. Spaceman must be able to operate controls, read dials and receive and transmit information within the limitations set by man, under stress, and enveloped in protective gear.

ANTHROPOMORPHISM, the ascribing of human form, or the characteristics of humanity, to deity; in a wider sense, the ascribing of human form or characteristics to any nonhuman object. The term is most properly applied to any religious statement, with either literal or symbolic intent, that depicts deity as subsisting wholly or partially in bodily form resembling that of a man, or as possessing qualities of thought, will, or feeling that are continuous with those experienced by men. Thus, expressions such as the "hand of God" and the "wrath of God" are equally illustrative of anthropomorphism.

In the wider sense of the word, anthropomorphism may be illustrated by any analogical transfer of human qualities to the lower animals, as when referring to their reasoning powers or ascribing to them such traits as courage or cowardice. The word may be applied even to descriptions of inanimate levels of reality in metaphors taken from human experience, as in speaking of the anger of a storm (*see* FIGURES OF SPEECH).

Throughout the history of religious thought various attitudes have been taken with respect to the propriety of anthropomorphism in statements purporting to describe God or the gods. One of the earliest in western thought to take explicit and critical note of religious anthropomorphism was Xenophanes (*c.* 580–485 B.C.), who perceived the provincialism in much theistic belief, observing, for example, that the Ethiopians and the Thracians fancied their gods, respectively, as black-skinned and as blue-eyed. He thought it unfitting that Homer and Hesiod "have ascribed to the gods all deeds that are a shame and a disgrace among men: thieving, adultery, fraud" (*Fragments*). Similarly, Plato repudiated the crass anthropomorphism of the popular Homeric mythology, enforcing the idea, in accord with Xenophanes, that God is one, and beyond human powers of comprehension. It is to be noted, though, that Plato defended the didactic value of anthropomorphic myth, if only God were assigned the highest virtues and not the lowest vices of men.

The classical Hebrew prophets, such as Amos and Isaiah, were vigorous critics of the gross forms of anthropomorphism popular in their times, reminding their hearers, for example, that the moral judgments of God were not based upon the tribal preferences that influence human judgments. The prophets did not entirely abandon anthropomorphism, however, but freely employed refined anthropomorphic symbols as indispensable to their concept of God as personal. The author of Ecclesiastes carried the critique of anthropomorphism further, approaching the idea of an impersonal cosmic force in place of the Hebraic personal God. It should be remarked that while many of the anthropomorphisms in the Hebrew scriptures are undoubtedly taken literally by their authors, many more are recognized and intended as poetic metaphors. In this regard, there is evidently a real difference between the intention of the relatively early statement that "the Lord used to speak to Moses face to face, as a man speaks to his friend" (Ex. xxxiii, 11), and that of the consciously poetic question directed by the Psalmist to God: "How long wilt thou hide thy face from me?" (Ps. xiii, 1).

While many thinkers have believed it possible to purge theism (*q.v.*) of all traces of anthropomorphism, many others have regarded anthropomorphism as not only inevitable, in some degree, but as essential to theistic knowledge and language. The latter judgment has been premised upon the observation that human knowledge and language in general are necessarily conditioned by man's experience of himself; if this is true, then the human subject invariably interprets nonhuman reality after analogies drawn from human experience.

There are those who have concluded from this apparent inevitability of anthropomorphism in human thought that theism as such is invalid and false. The view that the idea of God is merely an illusory projection of the human self, argued by such thinkers as Ludwig Feuerbach and Sigmund Freud, has been an influential example of this general position.

Others, equally convinced that anthropomorphism is inescapable in language about God, have argued as plausibly that there is no logical connection between this fact and the question of the validity and truth of theistic belief as such; the presumption that our *thought* and *speech* about God are subjectively coloured by our human experience is not a proper argument against the objective *reality* of God. It is often urged that the alternative to anthropomorphism in any form is either *agnosticism* (*q.v.*) or a view of God so abstract as to be religiously neutral.

BIBLIOGRAPHY.—Exposition of the idea of God as illusory is given in L. Feuerbach, *The Essence of Christianity*, trans. by George Eliot, particularly ch. i–iii, and in S. Freud, *The Future of an Illusion*, trans. by W. D. Robson-Scott (1949). A typical defense of anthropomorphic theism is given in B. H. Streeter, *Reality*, ch. iv and v (1926). ANTIARCHA: *see* PLACODERM.

ANTIBES, a town in southeastern France in the *département* of Alpes-Maritimes, is on the eastern side of the Garoupe Peninsula across the bay from Nice, from which it is 13 mi. by road. Pop. (1962) 24,370. The town is a holiday resort and a port for pleasure craft. Juan-les-Pins, close by, has a casino and long sandy beaches. The Grimaldi Museum contains a collection of paintings, including works by Pablo Picasso.

ANTIBIOTICS are chemical compounds, elaborated by particular species of plants and animals, that in very small amounts are harmful to certain other living things. The word derives from antibiosis (*see* below). The ability to form antagonistic substances occurs widely in nature, among organisms large and small, aquatic and terrestrial; but commonly the term antibiotic is restricted to compounds of microbial origin, especially those produced and used to combat other, injurious microorganisms. Among such "germs" are the parasites (notably bacteria) that infect and sicken man, his domesticated animals, and his crops: hence the utility—scientifically exploited only since the mid-20th century—of antibiotics in medicine and husbandry.

History.—Certain moldy materials—soils, lichens, decayed vegetable matter—were used empirically by primitive peoples to treat disease long before the role of microbes in infection was understood. Once this became known, in the 19th century, Pasteur and others began purposeful attempts to exploit microbial antagonism for man's benefit. Curing an infectious disease by trying to establish a second, antagonistic infection seemed logical but proved impractical: the task of extracting the active principle

from antagonistic microbes so as to obtain pure materials of uniform potency was beyond the technology of that era. At least one crystalline substance, mycophenolic acid, was isolated (1896) but it was not thoroughly evaluated.

Interest in the possibility of chemotherapy (*q.v.*) was quickened with the development of medicinal arsenicals (1910 and after) and the sulfonamides (1932 and after), and by the discovery of penicillin (*q.v.*) by A. Fleming (*q.v.;* 1928), gliotoxin (1936), griseofulvin and tyrothricin (1939), and other antimicrobial products of microorganisms. Successful isolation of Fleming's penicillin by E. Chain and H. W. Florey (*qq.v.*) at Oxford University (beginning in 1939) and of actinomycin (1940) and streptomycin (1944) by S. A. Waksman (*q.v.*) and associates at Rutgers University prompted intensive, worldwide exploration of antibiotics. More than 1,000 were reported in the ensuing quarter-century and several proved to be sufficiently safe and effective for therapeutic use in human medicine. Penicillin largely replaced the sulfonamides for the treatment of infection by Gram-positive cocci. (Positive, negative, or variable response to Gram's staining technique is a criterion for classifying bacteria in fundamental ways, including their reaction to antibiotics; *see* BACTERIA.) Streptomycin, which affects many Gram-negative pathogens, proved useful against tuberculosis. Bacitracin was announced in 1945 and polymyxin in 1947. Chloramphenicol (1947) was the first truly broad-spectrum antibiotic, active against rickettsial and typhoid fevers as well as many other bacterial infections. Other antibiotics followed in rapid succession, among them chlortetracycline (1948), neomycin (1949), oxytetracycline and nystatin (1950), viomycin (1951), erythromycin and carbomycin (1952), tetracycline (1953), oleandomycin and spiramycin (1954), amphotericin, cycloserine, novobiocin, and vancomycin (1955), ristocetin (1956), kanamycin (1957), paromomycin and rifamycin (1959), and lincomycin (1962). Meanwhile, numerous structural modifications of penicillin, cephalosporin, and tetracycline were prepared, and several of these proved to possess medicinal value.

Some Widely Used Antibiotics

Group and chemical nature	Nonproprietary name (with proprietary examples)	Empirical formula	Chief source microorganism	Active mainly against*	Routes of administration
penicillins and cephalosporins (water-soluble acids, α-amino-β-lactams fused to a sulfur-containing ring)	benzylpenicillin, or penicillin G	$C_{16}H_{18}N_2O_4S$	*Penicillium chrysogenum*	G+ bacteria	oral, parenteral, topical
	phenoxymethylpenicillin, or penicillin V	$C_{16}H_{18}N_2O_5S$	*Penicillium chrysogenum*	G+ bacteria	oral
	methicillin (Celbenin, Dimocillin, Staphcillin)	$C_{17}H_{20}N_2O_6S$	semisynthetic from 6-aminopenicillanic acid (6-APA)	G+ bacteria, including staphylococci resistant to benzylpenicillin	parenteral
	cloxacillin (Orbenin, Tegopen)	$C_{19}H_{18}ClN_3O_5S$	semisynthetic from 6-APA	G+ bacteria, including staphylococci resistant to benzylpenicillin	oral
	ampicillin (Omnipen, Penbritin, Polycillin)	$C_{16}H_{19}N_3O_4S$	semisynthetic from 6-APA	G+ and some G− bacteria	oral, parenteral
	cephalothin (Keflin)	$C_{16}H_{16}N_2O_6S_2$	semisynthetic from 7-aminocephalosporanic acid	G+ and some G− bacteria	parenteral
tetracyclines (amphoteric, highly substituted naphthacene derivatives)	chlortetracycline (Aureomycin)	$C_{22}H_{23}ClN_2O_8$	*Streptomyces aureofaciens*	G+ and G− bacteria, rickettsiae	oral, parenteral, topical
	demethylchlortetracycline (Declomycin, Ledermycin, Declostatin with nystatin)	$C_{21}H_{21}ClN_2O_8$	*Streptomyces aureofaciens*	G+ and G− bacteria, rickettsiae	oral, topical
	oxytetracycline (Terramycin, Terrastatin with nystatin)	$C_{22}H_{24}N_2O_9$	*Streptomyces rimosus*	G+ and G− bacteria, rickettsiae	oral, parenteral, topical
	tetracycline (Achromycin, Omegamycin, Panmycin, Polycycline, Steclin, Sumycin, Tetracyn, Tetrex)	$C_{22}H_{24}N_2O_8$	*Streptomyces* (spp.) or dechlorination of chlortetracycline	G+ and G− bacteria, rickettsiae	oral, parenteral
miscellaneous	chloramphenicol (Chloromycetin)	$C_{11}H_{12}Cl_2N_2O_5$ (*p*-nitrophenylserinol derivative)	*Streptomyces venezuelae* or synthesis	G+ and G− bacteria, including *Salmonella typhosa;* rickettsiae	oral, parenteral, topical
	novobiocin (Albamycin, Cathomycin, Panalba with tetracycline)	$C_{31}H_{36}N_2O_{11}$ (3-aminocoumarin derivative)	*Streptomyces* various species	G+ bacteria	oral, parenteral
	lincomycin (Lincocin)	$C_{18}H_{34}N_2O_6S$ (derivative of methyl 6-amino-1-thioöctapyranoside)	*Streptomyces lincolnensis*	G+ bacteria	oral, parenteral
	griseofulvin (Fulvicin, Grifulvin, Grisovin)	$C_{17}H_{17}ClO_6$ (substituted coumaranone derivative)	*Penicillium griseofulvum* and *P. janczewskii*	fungi	oral
macrolides (large ring lactones with at least one sugar moiety)	erythromycin (Erythrocin, Ilotycin, Ilosone, Pediamycin)	$C_{37}H_{67}NO_{13}$	*Streptomyces erythreus*	G+ bacteria	oral, parenteral, topical
	triacetyloleandomycin (TAO, Cyclamycin)	$C_{41}H_{67}NO_{15}$	*Streptomyces antibioticus*	G+ bacteria	oral
	nystatin (Mycostatin, Mysteclin with tetracycline)	$C_{46}H_{77}NO_{19}$ amphoteric tetraene	*Streptomyces noursei* (and other species)	fungi	oral, topical
aminoglycosides (water-soluble bases containing amino sugars)	streptomycin	$C_{21}H_{39}N_7O_{12}$	*Streptomyces griseus*	G+ and G− bacteria, tubercle bacillus	oral (not absorbed), parenteral, topical
	neomycin B	$C_{23}H_{46}N_6O_{13}$	*Streptomyces fradiae*	G+ and G− bacteria	oral (not absorbed), topical
	kanamycin A (Kantrex)	$C_{18}H_{36}N_4O_{11}$	*Streptomyces kanamyceticus*	G+ and G− bacteria	oral (not absorbed), parenteral
	paromomycin I (Humatin)	$C_{23}H_{45}N_5O_{14}$	*Streptomyces rimosus* forma *paromomycinus*	G+ and G− bacteria, some protozoa	oral (not absorbed), topical
polypeptides (cyclic polyamides)	bacitracin A	$C_{66}H_{103}N_{17}O_{16}S$	*Bacillus licheniformis*	G+ bacteria	oral, parenteral, topical
	polymyxin B (Aerosporin)	$C_{56}H_{98}N_{16}O_{13}$	*Bacillus polymyxa*	G− bacteria, particularly *Pseudomonas aeruginosa*	oral, parenteral, topical
	polymyxin E = colistin A (Coly-Mycin)	$C_{53}H_{100}N_{16}O_{13}$	*Bacillus colistinus*	G− bacteria, particularly *Pseudomonas aeruginosa*	oral, parenteral, topical

*G+ denotes bacteria that are stained by Gram's stain, and G− those that are not.

Antibiosis (Greek for "against life") is antagonistic association between organisms; *i.e.*, the opposite of symbiosis. It results in harm to one of the associates, manifested by reduced or distorted growth or by death. Antibiotic substances, as agents of antibiosis, damage or destroy vital processes or structures of susceptible organisms.

Modes of Action.—How do antibiotics act? Surely so diverse an array of substances must act in diverse ways and upon more than one of the countless biochemical activities of organisms. The penicillins, D-cycloserine, novobiocin, and bacitracin accumulate in the cytoplasmic membrane of staphylococci and other Gram-positive bacteria and there prevent the formation of new cell wall, thus blocking the completion of cell division which is the basis of multiplication and growth. Polymyxins and certain other antibi-

otics act on Gram-negative bacteria in the resting stage as well as the dividing stage, combining with constituents of the cell membrane in a way that increases membrane permeability and hence allows the escape of vital substances. Chloramphenicol and several other antibiotics act on Gram-positive and Gram-negative bacteria by interfering with crucial steps in intracellular protein synthesis, upon which depend the very substance as well as all the metabolic activities of the organism. (*See* also ANTIMETABOLITES.)

Resistance.—Among the characteristics peculiar to life are diversity, adaptability, change; and these features are no less true of microbes than of men. We may think of the presence of an antibiotic as an environmental stress that eliminates the susceptible members of a microbial population so that only resistant members survive and multiply. In theory, after a time the entire population may become resistant and the antibiotic ineffective; but, in spite of this tendency, drastic change in microbial populations is uncommon. Furthermore, science has been able to deal quickly and effectively with the resistance problem. Thus, emergence of benzylpenicillin-resistant strains of staphylococci, particularly in hospitals in the 1950s, was the incentive for intensified research that resulted in the development of many new antibiotics, among them penicillins with new properties.

Medical Uses.—*Groupings.*—Antibiotics may be grouped to suit the biologist interested in classification of the source microbes; the organic chemist concerned with antibiotic structure and hence properties; or the biochemist concerned with mode of action. The physician is best served by grouping on the basis of the spectrum, or scope, of their antibiotic activity. The broad-spectrum antibacterial and antirickettsial group encompasses chloramphenicol and the tetracyclines. Bacitracin, the macrolides, novobiocin, lincomycin, the penicillins, and cephalothin exemplify the medium-spectrum group active principally against Gram-positive bacteria. Other widely used medium-spectrum antibiotics active against many Gram-negative as well as Gram-positive bacteria include streptomycin, neomycin, kanamycin, and paromomycin—all water-soluble, basic aminoglycosides. The polymyxins are examples of narrow-spectrum antibacterials. Among antifungal antibiotics are griseofulvin and several polyenes (*e.g.*, amphotericin, candicidin, nystatin). Antibiotics active against parasitic protozoa include fumagillin and paromomycin. Several antibiotics possess activity that is inhibitory to viruses and the growth of cancers, but in the late 1960s none was considered sufficiently safe and effective for general use in clinical medicine.

Administration.—Mode of administration to patients is governed by the properties of the antibiotic and by the anatomic locale of the infection. If the drug is poorly absorbed from the intestinal tract (*i.e.*, if it remains within the tract) it may be given by mouth to treat a gastrointestinal infection; conversely, if it is well absorbed (*i.e.*, if it spreads from the tract to other parts of the body) it may be given by mouth to treat a systemic or topical infection. Some antibiotics are commonly administered parenterally (typically by injection) for systemic infection or locally (typically in salves or lotions) for topical infection. Size and frequency of the dose are determined by the susceptibility of the infecting microbe; the accessibility and the acuteness or chronicity of the infection; the absorption, distribution, and fate of the drug in the body; and the patient's age and his weight or surface area. All of these factors must be correlated with the amount of active ingredient in the drug, since a variety of pharmaceutical preparations is available. Some of the early antibiotics, notably penicillin and streptomycin, were first used before they had been purified, and this necessitated the employment of arbitrarily defined "units" to quantify the antibiotic activity; such units still persist. A few antibiotics act synergistically (*i.e.*, they reinforce each other in combination), and these may be given together at the discretion of the physician; but products containing quantitatively fixed combinations of antibiotics are deprecated by expert clinicians.

Side Effects.—Being potent substances, antibiotics frequently cause biological effects other than the anti-infective action intended. The physician must therefore weigh the desired benefits against predictable side effects. Orally administered antibiotics disrupt the normal, mixed microbial flora of the bowel and may

BY COURTESY OF LEDERLE LABORATORIES DIVISION, AMERICAN CYANAMID CO

GROWING CULTURES OF MOLD FROM SOIL SAMPLES IN LABORATORY DISHES. CULTURES SUCH AS THESE ARE USED IN ANTIBIOTIC RESEARCH

thereby cause intestinal disturbances or permit certain species of bowel bacteria or yeasts to multiply to pathogenic levels. Parenterally or topically administered antibiotics may incite drug reactions of the skin, such as flushes, rashes, wheals, or swelling of the lips or tongue. Injection of some antibiotics may so hypersensitize a patient as to make him intolerant to further treatment with the same or a related antibiotic. Unless dosage is carefully regulated, some antibiotics may damage peculiarly vulnerable internal structures such as the hearing and balance mechanism of the inner ear or the excretory tissues of the kidney; or they may inhibit normal activity of the blood-forming tissues of the bone marrow. Some antibiotics may accumulate to toxic levels if dosage is not appropriately reduced for infants, with their immature detoxification mechanisms, or for persons with infection-impaired kidney function.

Nonmedical Uses.—A few antibiotics are widely used in animal husbandry, principally as feed additives to enhance the fattening of food animals but also to preserve semen for artificial insemination. Antibiotics have been used by food processors to lessen spoilage of poultry, fish, and vegetables. Such uses are scattered and are subject to legal limitation in some countries because prolonged exposure of healthy human beings to low residual levels of an antibiotic in food may be harmful: individuals could become sensitized and hence unable to tolerate an antibiotic that might be needed later to treat a serious infection. Possible effects on the microflora of the human body and environment might be even more harmful. Low levels of antibiotics could perhaps replace normally drug-susceptible microbes with resistant strains difficult to combat if they should ever become pathogenic. It has been suggested that these hazards could be avoided by using only nonmedicinal antibiotics in feeds and foods.

Antibiotics are sometimes used to combat infectious diseases of cultivated plants, and to prevent microbial contamination of industrial processes and products and of mammalian-cell cultures used to propagate viruses. Narrow-spectrum antibiotics added to laboratory media inhibit unwanted microorganisms and thus facilitate isolation of desired microbes from contaminated specimens.

Commercial Production.—Most industrialized countries produce at least one antibiotic, and many produce several, in privately or publicly owned manufacturing plants. Because of the specialized technical training and equipment required, extensive research and development personnel and facilities are associated with the production enterprises. The antibiotic industry in the United States produced in 1965 more than 6,500,000 lb. (3,000,000 kg.) of product with a manufacturers' value of $437,000,000.

Most of the commercial antibiotics are manufactured by cultivating a highly productive strain of the source microorganism in tanks of about 5,000 to 20,000 gal. (19,000 to 76,000 l.) capacity and isolating the pure antibiotic from the fermented broth. The

fermentation tank is partly filled with a suitable liquid culture medium, sealed to prevent contamination, and seeded with the culture. The required aerobic conditions are achieved by bubbling sterilized air through the broth medium and stirring vigorously and more or less continuously during the several days needed by the organism to multiply and form the antibiotic. Temperature and other factors are precisely regulated. Isolation of the pure antibiotic from the fermented broth involves several steps (modified to suit the nature and properties of the compound): filtration, extraction, precipitation, adsorption and elution, ion-exchange chromatography, and crystallization. Yield may be as high as several grams of pure antibiotic per litre of fermented broth.

Some of the commercial antibiotics—certain of the penicillins, cephalosporins, and tetracyclines—are manufactured by chemical modification of a related fermentation product. A few, including chloramphenicol and cycloserine, are so simple in molecular structure as to be amenable to artificial synthesis, and these are manufactured chemically.

The labels of all commercial antibiotics give the common, or nonproprietary, name of the antibiotic. Most also bear the proprietary name or trademark of the manufacturer. Since a patient's physiologic response depends on pharmaceutical formulation as well as on the active ingredient, factors such as particle size, solubility, disintegration time, and freedom from contaminants affect the quality and reliability of the prescription. Such characteristics are more likely to be found in the trademarked products because the manufacturers must meet high standards of continuous quality control.

ANTICATHODE, the target inserted in an X-ray tube on which the high-speed electrons, or cathode rays (*q.v.*), are directed. In tubes with a separate anode the anticathode is generally connected electrically, and outside the tube, to the anode. In a Coolidge tube the anticathode acts also as the anode. On the impact of a sufficiently swift electron, the anticathode gives forth an X radiation characteristic of the material of which it is composed. *See* X Rays: *Excitation of X Rays;* Electricity: *The Coolidge X-Ray Tube.*

ANTICHRIST, the chief of the enemies of Christ. The earliest mention of the name Antichrist, which was probably first coined in Christian eschatological literature, is in the Epistles of St. John (I John ii, 18, 22; iv, 3; II John, 7). The conception of a mighty ruler who will appear at the end of time, and whose essence will be enmity to God, however, is older, and traceable to Jewish eschatology.

Jewish Conception.—The origin of the conception is to be sought in the first place in the prophecy of Daniel, written at the beginning of the Maccabaean period. The historical figure who served as a model for the Antichrist was Antiochus IV Epiphanes, the persecutor of the Jews, and he impressed indelible traits upon the conception. Since then ever-recurring characteristics of this figure are that he would appear as a mighty ruler at the head of gigantic armies, that he would destroy three rulers (the three horns, Dan. vii, 8, 24), persecute the saints (vii, 25) and devastate the Temple of God. In later times the tyrant who was God's enemy became a figure of prophecy, applied to various situations of crisis. Thus for the author of the Psalms of Solomon (*c.* 60 B.C.) the Roman general Pompey was the Adversary of God; the tyrant whom the Assumption of Moses (*c.* A.D. 30) expects at the end of all things possesses, besides the traits of Antiochus IV, those of Herod the Great. The eschatological imagination of the Jews was later influenced by the figure of the emperor Caligula (A.D. 37–41), who is known to have given the order, never carried out, to erect his statue in the Temple of Jerusalem. The so-called "little apocalypse" of Mark xiii (Matt. xxiv) may have been influenced in transmission by this event or, more probably, by the book of Daniel. Later Jewish and Christian writers of apocalypses saw in Nero the tyrant of the end of time.

Some of the roots of this eschatological fancy probably are to be sought in a purely mythological and speculative expectation of a battle at the end of days between God and the Devil, which has no reference whatever to historical occurrences. This idea had its original source in the apocalypses of Iran, for these are based upon the conflict between Ahura Mazda and Ahriman (*qq.v.*) and its consummation at the end of the world. This Iranian dualism entered late Jewish eschatology in the 2nd century before Christ, as is shown by the Dead sea scrolls. In this literature the name of the Devil often appears as Belial, a name which also played a part in the Antichrist tradition. The conception of the strife of God with the Devil was further interwoven, before its introduction into the Antichrist myth, with another idea of different origin, namely, the myth derived from the Babylonian religion of the battle of the supreme God (Marduk) with the dragon of chaos (Tiamat). This was originally a myth of the origin of things, which, later perhaps, was changed into an eschatological one, again under Iranian influence (*see* Babylonia and Assyria: *Religion*). Thus the Devil, the opponent of God, appeared in the end often also in the form of a terrible dragon-monster; this appears most clearly in Rev. xii. This myth—that the mighty Adversary of God was but the equivalent in human form of the Devil or of the dragon of chaos—exercised a formative influence on the conception of Antichrist. Only thus can it be explained how his figure acquired numerous superhuman and ghostly traits, which cannot be explained by any particular historical phenomenon. Thus the figure of Antiochus IV had already become superhuman when, in Dan. viii, 10, it is said that the little horn "grew great, even to the host of heaven; and some of the host of the stars it cast down to the ground." Similarly Pompey, in the second psalm of Solomon, was obviously represented as the dragon of chaos, and his figure exalted into myth. Finally, Antichrist received, at least in the later sources, the name originally proper to the Devil.

Early Church.—From the Jews, Christianity took over the idea. It is present in certain passages specifically traceable to Judaism. A fundamental change of the whole idea from the specifically Christian point of view is signified by II Thess. ii. Antichrist here appears as a tempter who works by signs and wonders and seeks to obtain divine honours; it is further signified that this "man of lawlessness" will obtain credence, more especially among the Jews because they have not accepted the truth. The conception, moreover, has become almost more superhuman than ever (*cf.* ii, 4, "proclaiming himself to be God"). The destruction of the Adversary is drawn from Isa. xi, 4, where it is said of the Messiah: "with the breath of his lips he shall slay the wicked." The idea that Antichrist was to establish himself in the Temple of Jerusalem (II Thess. ii, 4) is very enigmatical, and has not been explained. The "abomination (*q.v.*) of desolation" has naturally had its influence upon it, and possibly also the experience of the time of Caligula. Remarkable also is the allusion to a power that still retards the revelation of Antichrist (ii, 6, etc.), an allusion that, in the tradition of the Fathers, came to be universally, and probably correctly, referred to the Roman empire.

This version of the figure of Antichrist, who may now really for the first time be described by this name, appears to have been at once widely accepted in Christendom. The idea that the Jews would believe in Antichrist, as punishment for not having believed in the true Christ, seems to be expressed by the author of the fourth gospel (John v, 43). The conception of Antichrist as a perverter of men led naturally to his connection with false doctrine (I John ii, 18, 22; iv, 3; II John 7). Finally the author of Revelation also made use of the new conception of Antichrist as a worker of wonders and seducer, and set his figure beside that of the "first" beast, which was for him the actual embodiment of Antichrist (xiii, 11, etc.).

As the figure of Nero ceased to dominate Christian imagination, the unhistorical, unpolitical and anti-Jewish conception of Antichrist, based especially on II Thess. ii, gained the upper hand, having usually become associated with the description of the universal

conflagration of the world which had also originated in the Iranian eschatology. In this form it is in great part present in the eschatological portions of Irenaeus' *Against the Heresies* (2nd century) and in Hippolytus' *de Antichristo* and commentary on Daniel (early 3rd century). In times of political excitement, during the following centuries, men appealed again and again to the prophecy of Antichrist. Then special prophecies, having reference to contemporary events, were pushed to the front, but in the background remained standing, with scarcely a change, the prophecy of Antichrist that is bound up with no particular time. In the 3rd century, the period of Aurelian and Gallienus with its wild warfare of Romans and Persians, and of Roman pretenders one with another, seemed especially to have aroused the spirit of prophecy. Antichrist prophecies also flourished during the period of the rise of Islam and of the crusaders.

Middle Ages.—In the middle ages the whole complex of these dramatic eschatological conceptions developed into a most powerful historical and political factor, especially in times of crisis. From the 11th century Antichrist, "the mystery of iniquity," became the predominant element. The tradition was chiefly based on the *Pseudo-Methodius* (in a Latin version) and the letter, *De ortu et tempore Antichristi*, in which the monk Adso allayed the anxieties of Queen Gerberga, wife of Louis IV (d. 954). Theoretically canonical teaching remained stable on the whole; there was, however, much elaboration in commentaries on the Apocalypse and in the Sibylline prophecies, especially the Tiburtine and Erythrean. At the end of the 12th century the apocalyptic writings of the abbot Joachim of Floris gave an exceedingly strong and optimistic impulse to the anxious eschatological expectations by predicting, for 1260, a third age of the Holy Spirit. But while Joachim only indicated to Richard I (Coeur-de-Lion) in 1190 that Antichrist was already born in Rome (which he often identified with Babylon), his fanatical followers, the Joachites among the Franciscan Spirituals, were nearly the first to brand as Antichrist a Christian emperor, Frederick II, whose cruelty and doubtful faith, whose oriental pomp and great stature fitted their conceptions of Antichrist. Thus the idea of incarnate evil was transferred into the midst of Christianity itself; but later others saw Antichrist also at the head of the church, in the imperious Boniface VIII and the wealthy John XXII. It became quite common for opponents, popes and emperors, Guelphs and Ghibellines, etc., to hurl this name at each other. Thus the conception of Antichrist was somewhat trivialized. In the 13th century the tradition of Antichrist had been summarized in the great encyclopaedias (Vincent of Beauvais) and systematized by the great scholastics (Thomas Aquinas). Equally special tracts on his advent increased on a considerable scale, especially at the University of Paris. But some prophets of Antichrist who followed reformatory purposes came into conflict with the inquisition; *e.g.*, the famous Catalan physician and lay theologian Arnaldus de Villa Nova (1297). Scholastic refutation of all eschatological conjectures was intensified and (for instance) presented in a most comprehensive survey by Henry of Harclay, chancellor of Oxford university (1313). But immense interest continued to be focused on the person and the date of the coming of Antichrist and "the signs of the times" preceding it: upheavals in nature, wars, pestilence, famine and other disasters. All those calculations survived failure after failure. Preachers spread warnings of the coming of Antichrist in order to call the people to repentance throughout the 14th and 15th centuries. But the resulting anxieties seem to have become so aggravated that at the fifth Lateran council (1516) preachers were prohibited from presenting the coming of Antichrist as imminent. The imagination of the laity had been also deeply stirred by representations of Antichrist in paintings, sculpture and poetry. Miracle plays popularized the fearful figure of Antichrist, the earliest being the German *Ludus de Antichristo* (12th century) which had a Ghibelline bias.

The conceptions of Antichrist took yet another turn when used as a terrifying weapon in the violent controversy of the great reformatory movements. Reformist leaders did not attack individual popes but the papacy itself as being Antichrist. In England John Wycliffe, his follower John Purvey and others used it as a most effective argument. In Bohemia where, from the 14th century, a great cultural development was associated with strong opposition to the evils in the church and in political and social life, Matthias of Janow, the forerunner of John Huss, also declared Antichrist to be present within the church, at its very head, and placed hopes of a reformation on the pope's destruction. This idea that evil was embodied in the head of the church itself, with the clergy as the "body of Antichrist," became the most powerful weapon to discredit and denigrate the see in Rome. In similar terms Huss contrasted Christ with his vicar, the pope, who, when given to the vices of pride, avarice, etc., blasphemously called himself *papa*. All these ideas became the dynamic force which drove Luther on in his contest with the papacy. He even incorporated them in the Articles of Schmalkalden. He did not attack the person of the pope as Antichrist, but the institution of the papacy, which in his view placed itself above the Word of God.

After the Reformation, emphasis on the Antichrist figure gradually diminished; for German pietists any church that was spiritually dead could be regarded as its equivalent. Among some modern Protestant theologians the "Antichrist" can be interpreted as whatever resists or denies the Lordship of Christ and tends to deify a political power, within either the church or the state. The Antichrist, however, must be specifically related to the Gospel in such a way as to provide a pseudo-Christian imitation of Christ. It has been argued that the very spread of Christianity means that the possibility of rebellion against God has grown. Generally speaking, the Antichrist figure is less significant in churches of a more Catholic or Orthodox nature, where there has been less concern about the details of apocalyptic predictions.

(B. M. H.-R.; R. McQ. G.)

ANTICLERICALISM, a term applied to public opinion hostile to the influence of the clergy in political and social affairs, has been used in Europe since the time of the Cathari (*q.v.*) but is associated in more recent history with the French Revolution and its aftermath. Becoming a political movement, it first sought to separate religious authority from civil government but later attempted also when possible to subordinate the church to state control. In Latin countries, particularly France, anticlericals became numerous and influential as early as 1650. Opposition to clerical influence also grew in Austria-Hungary and Germany after 1800, and gradually took root throughout Europe as well as in Central and South America. (For anticlericalism in the U.S., *see* KNOW-NOTHING PARTY.) Three principal forms may be identified. The first, developing during the 18th century, was based on opposition to clerical privilege, often corrupt, as established by feudalism. The second is associated with the rise of liberalism, which in general deemed the clergy servile to the throne, or outmoded from the point of view of science. The third, endorsed by totalitarian systems of the right or left, considered religion the "opiate of the people," administered by a clergy chronically opposed to the "race," the "nation," or "democracy."

France.—Protestantism was seldom a major target of anticlerical sentiment until after the rise of Communist, Fascist or National Socialist governments. But the Catholic ideal of a universal church transcending national allegiances, committed to accepting the supremacy of the papacy in the realms of morals and belief, and sharing with the monarchies over a long period the rule of human society, was strongly under attack in France during the 18th century. Though fed to some extent by the tradition of

Gallicanism, skeptical inquiry, ably represented by Voltaire and the Encyclopaedists, was above all the concern of men who chafed under royal censorship and the influence of a clergy they thought medieval and obscurantist. They inveighed against *l'infâme*, by which Voltaire meant not religion but a priestly caste he termed hidebound, illiterate and absolutist. The plight of peasant and urban worker alike then aided the rapid growth of anticlericalism in the cities and some countrysides. The culmination was the French Revolution's bloody and uncompromising assault on the Catholic Church. The Revolution began by abolishing privileges and confiscating property; it ended in violent persecution, the mutilation of churches and civil war. In 1801 Napoleon ended the Revolution, signed a concordat with the papacy, and "established" the church as a religious agency supported by and subservient to the emperor. The manner in which all this was done, by making a virtual satrap of the pope, aroused sympathy with the church.

The Holy Alliance that liquidated the era of Napoleon reflected the mood of a Europe appalled by the consequence of political passion and therefore at least in part eager to restore older political institutions. Romantic admiration for the middle ages and monasticism won many writers and intellectuals over to conservatism. New religious orders were established, having educational or caritative (rather than contemplative) objectives. Not all Catholics supported the "reunion of throne and altar," but in France the majority of them did. In reality the Revolution had profoundly changed the social order. The bourgeois had become the hub the economic and intellectual activity turned round, and the bourgeois was nationalistic and emancipated. When he reacted against Bourbon rule, he gave a once more emerging anticlericalism an opportunity to ally itself with liberalism and constitutionalism. The new anticlerical was normally a rationalist, or freethinker, who considered the church outmoded, indifferent to life in this world, superstitious and unable to evaluate modern scientific progress. Anticlericals advocated a "lay state," neutral to all faiths and restricting each to the purely spiritual realm. Catholicism was to become one of the varieties of religious opinion, competing with other opinions in a free market of ideas, and not a privileged creed. Anticlericals were also motivated by nationalism, which had emerged as an ideal during the Revolution. (*See* also ROMAN CATHOLIC CHURCH: *The Church After 1815*.)

The program of the anticlerical liberals included the suppression of religious orders, separation of church and state, civil marriage and divorce, secular education, and complete freedom to profess a religion or none. Because of restrictions imposed by the proclerical governments then in power, anticlericalism was often forced underground. Secret societies, notably the Freemasons, became centres of anticlerical activity. For their part supporters of the Bourbons were dubbed the *parti prêtre*, and as their opponents grew in number they also enlisted prominent Catholics. The Revolution of 1830, which brought the Orleanist Louis Phillipe to the throne, was a setback to clericalism and absolutism alike.

Italy.—Spreading from France, anticlerical ideas and methods were adopted, in varying ways, in Italy, Spain, Portugal, Belgium and Central and South America. In Italy anticlericalism was fused with nationalism and liberalism. Pope Pius IX, defending his position as temporal ruler of the Papal States, opposed Italian unity. When Camillo Cavour embarked on his career as architect of a united Italy, he put through the Piedmontese parliament a series of anticlerical laws, abolishing the civil jurisdiction of canonical courts and suppressing many monasteries. Cavour's slogan, "a free church in a free state," was adopted by the anticlerical liberals of Italy.

Spain.—The Napoleonic invasion (1808) started an anticlerical movement in Spain. The constitution of 1812 abolished the Inquisition and restricted the number of religious orders but recognized Catholicism as the established church. This constitution was in turn abrogated when Ferdinand VII was restored to the throne in 1814. Anticlericals reacted bitterly, and from that time until 1939 the struggle between the right and left in Spain was far more a conflict between clericals and anticlericals than elsewhere in Latin Europe. Carlos, brother of Ferdinand, revolted against Queen Isabel II. The wars (1872–1876) which attended these uprisings saw many atrocities committed by clericals and their foes alike. Then the growth of the socialist movement after 1870 increased the truculence of anticlericalism. The socialists put the church in the position of being the chief defender of the established social and economic order. But by 1848 many bourgeois liberals, fearing that socialism would overthrow that order, had begun to desert anticlericalism. This trend was reversed when, in 1864, Pope Pius IX issued the *Syllabus of Errors*, the more advanced liberals viewing this *Syllabus* as a declaration of war on modern progress.

France.—The creation of the Third Republic in France (1870) was followed by constant conflict between clericals and anticlericals. First came the struggle of the years between 1871 and 1879, when royalist-clerical parties opposed republican-anticlerical parties. Léon Gambetta phrased the slogan, *"le cléricalisme, voilà l'ennemi."* The victorious republicans enacted a good deal of anticlerical legislation. The Jesuits were suppressed (1880), and the Ferry laws (1881–1882) established free, secular education, compulsory civil marriage, and the opportunity for divorce. The second conflict took place as a result of the bid of Georges Boulanger (*q.v.*) for dictatorial powers, and ended with a republican, anticlerical triumph. The third took place during the Alfred Dreyfus (*q.v.*) affair (1894–1906), when an anticlerical republican bloc was formed, consisting of all republican groups in the chamber of deputies, determined to oust royalists, militarists and clericals from public life. Further anticlerical legislation resulted. The Law of Associations (1901) suppressed nearly all of the religious orders in France and confiscated their property, and the separation law (1905) sundered church and state.

During World War I clericals and anticlericals joined in the defense of the country. Anticlericalism subsided, despite minor incidents. During the following three decades, some reconciliation was effected. Pope Pius XI condemned the antirepublican movement, *l'Action française*, and the popular front government formed by Leon Blum (1936–1937) fostered cordial relations with the church. After the fall of France during World War II, many Catholics joined in the underground struggle against the forces of Hitler. When hostilities had ended, a new prodemocratic Catholic party emerged. While anticlericalism had not disappeared in liberal circles, it was now identified with Communism.

Italy.—In Italy, after the unification, the struggle between clericals and anticlericals continued, though in a milder form than in France. The designation of Rome as the capital city ended the temporal power of the popes. A series of anticlerical laws were passed, decreasing the number of monastic foundations, suppressing university theological faculties, and establishing civil marriage. But no divorce law was enacted, nor was religious instruction banned from the schools. The Law of Guarantees accorded the pope full power to exercise his spiritual functions. Pius IX did not, however, recognize the Italian government and in 1874 forbade Catholics to participate in political activities. This caveat was not ended until 1919. The advent to power of Benito Mussolini in 1922 for a time intensified anticlericalism in Italy, Fascism claiming absolute control by the state. But despite some continuing papal opposition, no serious conflict occurred. In 1929, the Lateran treaty was signed, ending the dispute over the temporal power by making the pope ruler of the small state of Vatican City. A subsequent concordat made religion obligatory in elementary and secondary instruction. Bishops were required to take an oath of loyalty to the state. These actions angered anti-Fascists and there were signs that Cavour's policy would again dominate if the regime fell. But when World War II ended, the ominous strength of Communism in Italy evoked strong support for the Christian Democratic party.

Spain.—In Spain the conflict between church and state was intensified after 1870. Barcelona, traditionally a centre of anti-Catholic feeling, now witnessed the formation of powerful syndicalist and anarchist groups. The first Spanish republic (1873) enacted some anticlerical laws but these were repealed or disregarded when the monarchy was restored in 1875. During an anticlerical outbreak in 1909, mobs burned churches and attacked

priests. As a pacification measure, religious orders were restricted in number and taxes were levied on their industrial enterprises. Civil marriage was made compulsory. The revolution of 1931 which established the second republic brought to power an anticlerical government. The legislation adopted resembled that of France. The government was, however, unable to curb mob attacks on churches and monasteries, during which priests and nuns were slain. Catholics mustered their forces in opposition. Counterrevolutionaries led by Gen. Francisco Franco Bahamonde declared war on the republic, and were reinforced by troops from Morocco. Hitler and Mussolini aided Franco; Stalin aided the republic, which in its death struggle fell under Communist domination. A Falangist dictatorship was established which repealed or ignored the anticlerical laws, though conflict between church and state did not cease.

Central and South America.—The struggle for independence from Spain and Portugal, which characterized the history of Central and South America during the 19th century, was often strongly influenced by ideas associated with the French Revolution, among them anticlericalism. Educated citizens, including upon numerous occasions some of the lower clergy, were attracted by currents of thought that seemed novel and vital by contrast with a generally stagnant ecclesiastical culture. The Freemasons in particular were respected as spokesmen for freedom, toleration and the scientific outlook. But it is difficult, in view of turbulent political events that led almost everywhere to a succession of dictators, to determine whether the recurring patterns of anticlerical activity—the suppression of religious orders, primarily the Jesuits; the confiscation of ecclesiastical property; the fostering of secular education, sometimes with a caveat against religious instruction; and the introduction of civil marriage and divorce—were due to an intellectual ferment caused by the French Revolution or whether they were primarily incidents in the constant tussle between factions for political control. The situation varied considerably from country to country. Though Colombia, for example, witnessed the enactment of anticlerical legislation and its enforcement during more than three decades (1849–1884), it soon restored "full liberty and independence from the civil power" to the Catholic Church (1888). In Venezuela on the other hand the government of Antonio Guzmán Blanco (1870–1888) virtually crushed the institutional life of the Church, even attempting to legalize the marriage of priests. Some of the restrictions were later relaxed, but on the whole anticlericalism remained dominant. Developments elsewhere were comparable either for rigour or eventual moderation. Not merely the impoverishment and enfeeblement of the church resulted, but a mounting reluctance on the part of the hierarchy to become embroiled in any controversy. As the lines between the wealthy, whether landholders or industrialists, and the indigent masses were drawn more sharply, the leaders of labour unions and other agencies struggling for social improvement were likely to repeat the dictum that "religion is the opiate of the people," or to seek affiliation with totalitarian movements, whether of the right or the left. Upon occasion there were strong outbursts of anticlerical resentment, one of the most noteworthy being that which took place in Mexico (1924–1938). Suppressive anticlerical legislation accompanied social reform. There were sanguinary uprisings by Catholics. Meanwhile the Papacy had manifested an increasingly liberal outlook, as evidenced by a series of concordats signed with Central and South American states after 1919; and subsequent to World War II efforts to form a Christian Democratic movement were begun.

Austria-Hungary and Germany.—In Austria-Hungary anticlericalism marked the reign of Joseph II (1765–1790). Strongly influenced by the ideas of the French Encyclopaedists and those of a kindred group in southwest Germany, Joseph held that the state must control all religious activities not identified with the "inner life" of the Church. Monasteries were secularized, the education of priests was regulated, and a number of provisions governing religious cult and practice were adopted. Most of these regulations were rescinded by later emperors, and for a time anticlericalism could be identified with opposition to the Habsburgs. But toward the close of the 19th century Socialism became the effective advocate of the lay state, and was opposed by the peasants, much of the middle class and the aristocracy. After the dissolution of the monarchy in 1918 anticlericalism was rampant in some of the succession states but by 1925 the struggle had abated. After the formation of a one-party, clerical *Volksfront* government in 1934 anticlerical sentiment waxed strong in Austria proper. But it lost its virulence during the period of Nazi rule.

Anticlericalism was not novel in Germany but it was strengthened intellectually by ideas generally accepted during the French Revolution. Free thought, with its principle of the "lay state," made headway particularly in southern Germany, and played a part in the revolutionary incidents of 1848. The rise of Marxian Socialism likewise brought large segments of the working population into the anticlerical camp. But Catholics in the populous Rhenish areas were prevailingly constitutionalists, in sympathy with some tenets of liberalism, and vigorous in support of social and electoral reform. Their political program, which led to the formation of the Centre party, included the defense of the rights of all religious minorities.

Shortly after the unification of Germany in 1871 Otto von Bismarck, adopting part of the liberal program, began the series of attacks on the Catholic Church known as the *Kulturkampf*. Anticlerical legislation was enacted, applicable in part to the empire as a whole and in part to the kingdom of Prussia. The number of religious orders was restricted, the Jesuits were banned, civil marriage was sanctioned, unco-operative priests were removed from their parishes, and a variety of measures were adopted to curb the freedom of the clergy. Resistance was punished, and some bishops were deposed. But by 1878 a desire to end the *Kulturkampf* was manifest, and during the next decade most of the anticlerical legislation was removed from the statute books. (*See* also LEO: *Leo XIII*.) The prohibition of the Jesuits remained in force, however, until 1917. The period of the Weimar Republic (1919–1933) was characterized by the grant of complete freedom to Catholics, though as a result of the activity of the Centre party some anticlerical comment was engendered.

The Nazi dictatorship (1933–1945) enforced its own anticlerical program on Catholics and Protestants alike. Hitler attempted to regulate his relations with the Vatican through a concordat, signed in 1933, but this was honoured in the breach rather than in the observance. Protestants were united, by ruse or force, in a German Christian Church. The ablest Protestant clergymen dissented, forming the heroic Confessing Church upon which heavy blows fell. Catholics opposed, often with genuine courage, a series of decrees affecting the liberty of preaching, the treatment of minorities, the control of education and the silencing of the press. Hundreds of clergymen, both Catholic and Protestant, were brought to trial, imprisoned or executed. Rigour was even greater in the conquered lands. Hitler planned, in the event of final victory, to reduce the Christian religion in his dominions to impotence. A decade after the end of World War II it appeared that the Nazi and Fascist ideologies had lost all but minor vestiges of their influence. Anticlericalism in Europe became a normal consequence of the support given by the Catholic Church to the Christian Democratic parties, or part of Communist doctrine.

Soviet Anticlericalism.—After the seizure by the U.S.S.R. of the Baltic states and of eastern Poland in 1939, repression fell heavily on the Catholic and Protestant Churches of Estonia, Latvia, Lithuania and Poland. Occupation and eventual subjection of the satellite countries and eastern Germany after the war were followed by usually less violent but nonetheless implacable actions in the area of religious activity. At the conclusion of notorious trials, the foremost prelates of Yugoslavia, Czechoslovakia, Hungary, Poland and Rumania were imprisoned. Many thousands of bishops, clergymen and faithful layfolk were sent to prisons or slave labour camps. Religious education and publishing were forbidden, only a handful of convents and monasteries were suffered to remain, and hospitals were secularized. The Catholic clergy in Albania was decimated, and the Uniate Churches in Rumania and Bulgaria were destroyed. During 1956 some amelioration of the situation was permitted in Poland. Russian (Communist) anticlericalism is characterized by unrelenting hostility to religion in

any form save that of complete subservience to the Kremlin. Its watchword is not the "lay state," but the "classless society."

See ULTRAMONTANISM.

(J. S. So.; G. N. S.)

ANTICOSTI, an island in the Gulf of St. Lawrence, a part of Saguenay county, in the province of Quebec, Can., about 400 mi. downstream from Quebec. It is 135 mi. long, and its greatest breadth is 30 mi. With a total area of 3,043 sq.mi., it contains an estimated 500,000,000 spruce, balsam and pine trees and some species of hardwood.

It was first sighted by Jacques Cartier in 1534 and named Assomption Island. Its present name, derived from an Indian dialect, was already used in the 17th century; it means "where bears are hunted." The island was ceded by France to Great Britain in 1763 and annexed to New Brunswick; under the terms of the Quebec act (*q.v.*) it became part of the Province of Quebec in 1774. Uninhabited for more than two centuries, the island was leased in 1895 by Henri Menier, French chocolate manufacturer, who developed the local resources and built a château at Port Menier, near the west end of the island. In 1926 ownership of Anticosti was transferred to the Consolidated Paper corporation of Montreal which has since administered the island, conducting lumbering operations and shipping pulpwood to its plants in the vicinity of Trois-Rivières on the St. Lawrence. The population is less than 1,000. (P. CA.)

ANTICYCLONE, a feature of weather maps and climatic charts appearing as a region in which the pressure is higher than in the surroundings; in common meteorological parlance, anticyclones often are simply referred to as "highs." The name anticyclone was introduced by Sir Francis Galton in 1861 to denote an atmospheric system opposite to a cyclone (*q.v.*). Whereas in a cyclone or low-pressure area the winds circulate in a counterclockwise sense in the northern hemisphere and clockwise in the southern hemisphere, the anticyclonic circulation is clockwise in the northern and counterclockwise in the southern hemisphere. In contrast with cyclones, which are usually areas of strong winds and bad weather, anticyclones ordinarily are characterized by fine weather and weak winds.

The most prominent anticyclones of the earth are the more or less permanent ones found over the oceans of both hemispheres at about latitude 30°. (*See* WIND.) They are oblong in shape, covering nearly the entire breadth of the oceans in these latitudes with the highest pressure centre somewhat to the east of the geometric centre. Their position and strength are important factors in forecasting weather for all latitudes, and for this reason they are referred to as the "centres of action" for the general circulation. In winter, anticyclones are found more or less regularly over the cold, high-latitude continents, notably in eastern Siberia, where they are the principal feature of the Asiatic winter monsoon (*see* MONSOON). These are called thermal anticyclones, since their formation is caused by cooling in the lower atmosphere, and they disappear or are displaced equatorward at upper levels. The oceanic anticyclones contain warm air, except possibly in a shallow layer next to the surface of the earth, and are called dynamic anticyclones. They maintain or even increase their intensity aloft.

ANTIDOTES, remedies for counteracting poisons. The following antidotes for special poisons are sometimes given in case of emergency, usually following and followed by an emetic, and whenever possible under the supervision of a physician. In general, antidotes for acid poisons are: ammonia (a teaspoonful to one-half pint of water) or limewater, plaster, magnesia or chalk. For alkali poisons, antidotes are vinegar, dilute acetic acid or lemon juice.

For an unidentified poison, the general rule is to give eggs, salad oil (except in phosphorus poisoning), flour and water or limewater (except for alkaline poisons), preceded by large drafts of water or milk, and to induce vomiting by placing the finger in the throat or by an emetic. Kitchen soap and water may be used several times repeated. The antidote is only one part of the treatment, which may include first an emetic, often followed by stimulants such as strong black coffee.

ANTIDOTES FOR SPECIAL POISONINGS

Alkalies: Dilute acids; vinegar, one glass to one quart of water; dilute acetic acid, 2%–3%; lemon juice; soothing fluid; oils; melted fat; milk; cream. (No emetic.)

Alkaloids (aconite, belladonna, strychnine, etc.): Gastric lavage with tannic acid or potassium permanganate; artificial respiration or oxygen therapy. Control excitement with barbiturates.

Antimony (tartar emetic, wine of antimony): Same as for mercury. Strong coffee or tea; one teaspoonful of tannic acid in one-half glass of water followed by eggs or milk.

Arsenic (Fowler's solution, paris green, Scheele's green, Schweinfurt green, arsenical dyes in papers and candies): Gastric lavage with sodium thiosulfate: sodium thiosulfate intravenously. Prevent dehydration with parenteral fluids.

Carbolic acid (creosote, guaiacol, creosol): Soluble sulfates, such as magnesium sulfate, sodium sulfate (epsom and Glauber's salts), dilute alcohol, raw eggs, flour and water, milk, castor or sweet oil. (No emetic.)

Copper (blue vitriol or bluestone, verdigris): Milk; eggs; soap; flour and water.

Depressants (chloral, barbiturates, etc.): Gastric lavage. Stimulants such as picrotoxin or metrazol; artificial respiration.

Formaldehyde: Bland drinks; milk; and oils.

Hydrochloric (muriatic), nitric (aqua fortis), oxalic, acetic, sulfuric (vitriol) acids: Weak alkaline drinks at once; ammonia (eight teaspoonfuls in one-half pint of water); baking soda; magnesia; chalk; lime; soap and water; or tooth powder. (No emetic.)

Iodine: Starch and water.

Lead: Gastric lavage and epsom salts to hasten elimination. If symptoms are acute, demobilize the lead by diet rich in calcium and phosphorus.

Mercury (corrosive sublimate or bichloride of mercury, blue ointment, oxide of mercury, black wash, yellow wash, cinnabar vermilion): Gastric lavage with sodium formaldehyde sulfoxylate; raw eggs; or milk. Sodium lactate for acidosis; parenteral fluids and sodium formaldehyde sulfoxylate intravenously. Treatment for shock.

Opium: No antidote (emetics and stimulants used). Artificial respiration if breathing stops. Repeated doses of central-nervous-system stimulants. Do not exhaust the patient by making him walk the floor.

Phosphorus: Magnesia in water; potassium permanganate, 1 to 1,000 solution in water; copper sulfate (bluestone in water); repeated five-grain doses to cause vomiting; turpentine; one-half teaspoonful in a glass of milk or water. Do not give oils or fats.

Plant poisoning: Plant poisons in general do not require an antidote, being treated by induced vomiting, stimulants and brisk purging, as with castor oil.

Prussic acid: Gastric lavage; amyl nitrite by inhalation followed by sodium nitrite and sodium thiosulfate intravenously. Methylene blue intravenously.

Ptomaine (poison from decayed meats, fish, vegetables, contaminated canned foods): (After emetic) castor oil, epsom salts

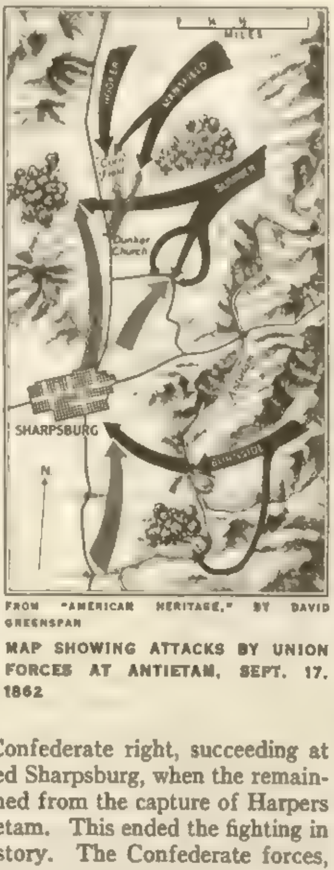
or other rapidly acting cathartic; enema of warm soapsuds with one teaspoonful of turpentine to the pint or two teaspoons of glycerine.

Silver preparations (silver nitrate, lunar caustic): Large drinks of salt water; soap; drafts of milk; baking soda.

ANTIENZYMES: *see* ANTIMETABOLITES.

ANTIETAM, BATTLE OF, one of the more important engagements of the American Civil War. It was fought on Sept. 17, 1862, and took its name from Antietam creek that has its source near Gettysburg, Pa., and flows almost due south to the Potomac river near Harpers Ferry, W.Va. It is sometimes referred to as the battle of Sharpsburg because the main fighting took place near the town of that name.

Following Gen. John Pope's defeat at the second battle of Bull Run (*q.v.*), Gen. *Robert E. Lee* advanced into Maryland as far as Frederick, northwest of Washington, D.C., with some assurance that he might capture the city. When he learned that Gen. George B. McClellan, again in command of the reorganized Federal army, was opposing his further advance, he withdrew toward the southwest. His plan was to hold McClellan at a possible stronghold at South mountain, which paralleled Antietam creek. Meanwhile, "*Stonewall*" *Jackson* was ordered to capture Harpers Ferry and rejoin *Lee*. With his forces thus divided, *Lee* was unable to hold South mountain and therefore took up positions due west of it along Antietam creek.



FROM "AMERICAN HERITAGE," BY DAVID GREENSPAN

MAP SHOWING ATTACKS BY UNION FORCES AT ANTIETAM, SEPT. 17, 1862

Here the battle of Antietam was fought as McClellan moved his army west against *Lee*. Gen. Joseph Hooker's corps attacked *Jackson* on *Lee's* left at 5 A.M. on Sept. 17. Hooker's advance promised well but met stubborn resistance and had to be supported by Gen. Joseph Mansfield's corps. Confederate counterattacks stopped and drove back the Federal forces, and then Gen. Edwin Sumner's corps was thrown into the battle, followed by a counterattack by Gen. *James Longstreet's* corps. The battle proceeded without notable success on either side from early morning until afternoon. McClellan's next move was to send Gen. Ambrose E. Burnside's corps against the Confederate right, succeeding at first. Burnside had almost captured Sharpsburg, when the remainder of *Jackson's* corps, freshly armed from the capture of Harpers Ferry, drove him back to the Antietam. This ended the fighting in one of the bloodiest battles of history. The Confederate forces, variously estimated at from 40,000 to 60,000, had lost between 9,000 and 10,000 killed and wounded; McClellan's force of from 70,000 to 90,000 (a portion of whom were not actively engaged) lost about 12,000. McClellan's orders for the day after the battle and following indicate that he expected another attack by *Lee* and he was therefore relieved when *Lee* retired into Virginia. Most military historians have strongly criticized McClellan's conduct of the battle.

Antietam is regarded as one of the decisive battles of the Civil War because it stopped one of the greatest threats to Washington during the war. McClellan blocked *Lee's* advance but failed to win a victory over him. The battle is sometimes cited as influencing Great Britain not to recognize the Confederacy, but this is largely conjecture. The outcome of the battle led Pres. Abraham Lincoln to issue a proclamation (Sept. 22, 1862) stating that he would, on the opening day of the new year, declare all slaves in the seceding states "forever free."

ANTIFEDERALISTS, the name given to those who opposed ratification of the United States constitution of 1787. Though a mixed group with diverse reasons for opposition, they were united by fear of the proposed increase in the authority of the national government and in the powers to be exercised by the congress. They believed that one republican government could not operate successfully over the entire nation, that the small size of the lower house of the legislature would make it impossible for all interests in the country to be represented and that the electoral system would operate to the advantage of the upper classes. They believed the proposed constitution violated the principle of separation of powers, and that it was drafted so loosely as to leave congress a dangerous latitude of discretion. They criticized the lack of a Bill of Rights, but were also opposed to the prohibition of religious qualifications for office-holding included in the constitution. They shared the distrust of human nature expressed in *The Federalist*, and feared that their liberties and interests would be jeopardized by a national government which would be beyond the control of the people of any particular state, and which many believed would have an aristocratic bias.

The Antifederalists were strong in the key states of Massachusetts, New York and Virginia; in North Carolina and Rhode Island they prevented ratification until after the new government had been established. Their advocacy of a Bill of Rights led to its adoption, and their opposition to a strong central government has not been without adherents in the subsequent history of the United States.

See also FEDERALIST PARTY; UNITED STATES (OF AMERICA): *Government*.

See Forrest McDonald, *We the People: the Economic Origins of the Constitution* (1958); C. M. Kenyon, "Men of Little Faith: the Anti-Federalists on the Nature of Representative Government," *William and Mary Quarterly*, third series, vol. xii, no. 1 (1955). (C. M. KE.)

ANTIFREEZE, a liquid used in cooling systems, particularly those of automobiles, to prevent freezing.

The various commercial brands of so-called permanent antifreezes are basically ethylene glycol, $C_2H_4(OH)_2$, a synthetic dihydroxy alcohol. Its boiling point of about 375° F. is well above the maximum cooling-system temperature and prevents loss by evaporation. Most other commercial antifreezes are basically methanol, CH_3OH, which boils at about 150° F. The boiling point of water is reduced by adding methanol. A solution that is one-third methanol and two-thirds water boils at about 180° F., a temperature that is not attained in normal operation with a thermostat set to open at 160° F. When stronger solutions are necessary, they must be tested periodically and replenished because of evaporation of the methanol. Test hydrometers indicate the percentages of antifreeze in solutions and their freezing points, employing the fact that addition of methanol makes the solution lighter and glycol makes it heavier than water.

Periodic maintenance checks for dilution and for the effectiveness of corrosion inhibitors are necessary for all antifreeze solutions. Also, seepage into the cylinders may cause serious lubrication difficulties. Though some factory-installed coolants (glycol ethers) have been recommended for continuous use over a two-year period, any significant dilution could result in loss of protection from freeze-ups or from rust and corrosion.

The following tabulation shows the percentages of either of the two types of antifreezes in water solutions corresponding to several freezing temperatures.

Temp. (° F.)	10	5	0	−5	−10	−15	−20	−25	−30	−35	−40
Glycol (%)	24	28	32	35	38	41	43	45	48	50	52
Methanol (%)	21	24	27	30	32	35	37	39	42	44	46

(O. C. C.)

ANTIFRICTION BEARINGS: *see* BEARING METALS; BEARINGS.

ANTIGONE, the name of two figures in Greek legend.

1. Antigone was the daughter born of the incestuous union of Oedipus (*q.v.*) and his mother, Jocasta. After her father's blinding, Antigone and her sister Ismene served as Oedipus' guides,

following him from Thebes into exile until his death near Athens (related by Sophocles in *Oedipus at Colonus*). Returning to Thebes they attempted to reconcile their quarreling brothers, but failed, afterward suffering the siege of the Seven Against Thebes (*q.v.*), in which both brothers were killed, Eteocles defending the city and his crown, Polyneices attacking. Their uncle Creon thereupon became king, and having visited the body of Eteocles with elaborate obsequies, forbad the removal of the corpse of Polyneices, condemning it to lie unburied to rot on the argument that he was a traitor. Antigone, moved by love of her brother and convinced of the injustice of the command, which violated divine law and normal usage, buried Polyneices secretly and performed his funeral service. For this she was ordered executed by Creon and was interred in a cave, where she hanged herself. Her beloved, Haemon, son of Creon, committed suicide. (This according to Sophocles' *Antigone;* but in Euripides, Antigone escaped and lived happily with Haemon, at least for several years.)

2. Antigone, sister of Priam, boasted to Hera of her beautiful hair, which the goddess then transformed to a mass of snakes. The gods took pity on her and turned her into a stork (Ovid, *Metamorphoses*). (T. V. B.)

ANTIGONUS I Cyclops or Monophthalmus ("the One-Eyed") (382–301 B.C.), Macedonian general and, after the death of Alexander III the Great (323 B.C.), ruler of a major part of the Macedonian empire. In 333 Alexander made him satrap of Greater Phrygia with the duty of protecting the communications of the invading army in this recently conquered area. After Alexander's death he was driven out by Perdiccas (*q.v.*), but was restored by Antipater (*q.v.*). At the settlement at Triparadisus in Syria (321), when Antipater became regent of the Macedonian empire, Antigonus was appointed commander of the royal army in the war against Eumenes (*q.v.*), whom he defeated in Asia Minor (320) and later, in a hard-fought campaign (318–316), in Mesopotamia and Media.

Antigonus revealed his ambition to reunite the divided Macedonian empire under himself when, after the final defeat and death of Eumenes at Gabiene in Persis (316), he claimed authority over the whole of Asia, dismissed and appointed satraps at will and seized royal treasure for his own use. The other leading generals of the empire, Ptolemy (*see* Ptolemies), Antipater's son Cassander, Lysimachus and Seleucus (*qq.v.*), formed a coalition against him, and a long war began. The first period of this war brought no decision; Antigonus had won over much of Greece, but he had lost a battle at Gaza in southern Palestine (312), as a result of which Seleucus conquered Babylonia and the eastern satrapies of Media and Susiana. In 311 Antigonus made peace with the other allies in order to concentrate his forces against Seleucus. During the next four years Antigonus failed to dislodge Seleucus from the eastern regions of the empire. In 306, after his son Demetrius, who had seized Athens from Cassander in 307, defeated Ptolemy's forces on Cyprus, Antigonus took the title of king for himself and his son, at last explicitly claiming the succession to Alexander. Both his attempt to invade Egypt (winter 306–305) and his siege of Rhodes, conducted by Demetrius (304), failed. But a new campaign by Demetrius in Greece (303–302) was brilliantly successful. In 301, however, the allies Cassander, Lysimachus and Seleucus brought about the defeat and death of Antigonus in the battle of Ipsus (*q.v.*) in Phrygia.

Antigonus was an excellent general and a vigorous and capable ruler. His support of the right of Greek cities to enjoy autonomy was essentially a weapon for use against his enemies (as was his revival of the Greek league—the League of Corinth—of Philip II of Macedonia and Alexander); but his policy was a sensible one, and it won him the friendship of the Greek states, notably Athens.

See also Index references under "Antigonus I" in the Index volume.

See R. H. Simpson, "Antigonus the One-Eyed and the Greeks," *Historia*, vol. viii (1959). (R. H. Si.)

ANTIGONUS II Gonatas (*c.* 319–239 B.C.), king of Macedonia from 276, was the son of Demetrius I Poliorcetes (*q.v.*). Left in charge of Greece when his father set out upon his final campaign in Asia (287), he at first had great difficulty in holding his own in wars against Pyrrhus, king of Epirus; Lysimachus; Antiochus I (*qq.v.*); Ptolemy Ceraunus (*see* Ptolemies); and some of the Greek cities. He assumed the title of king on his father's death in 283, but it was not until 276 that he gained control of Macedonia. In 279 he had concluded peace with Antiochus, whose sister Phila he married, and thereafter his foreign policy was marked by friendship with the Seleucids. However, he had Ptolemy II as a dangerous enemy in Greece and the Aegean.

When Pyrrhus returned from Italy in 274 after the battle of Beneventum he attacked Macedonia and deprived Antigonus of large tracts of territory before passing on to southern Greece where he was killed at Argos in 272. Antigonus thereupon recovered his position in Macedonia and Greece. Sparta and Athens, supported by Egypt, fought against him (unsuccessfully) in the Chremonidean War (267–262); later, by defeating the Egyptian fleet in an important battle off Cos (258), he won control of the Aegean sea. Between 250 and 245 a disloyal lieutenant called Alexander deprived him of control of Corinth and Chalcis in Euboea, the two bases from which he dominated southern Greece; but he won a second victory at sea over Ptolemy off Andros (246) and once more secured his position on the mainland. The end of his reign saw Corinth again lost (243) and an inconclusive struggle with the Achaean league under Aratus (*q.v.*) of Sicyon.

Antigonus was a moderate man with many admirable qualities. He rebuilt the power of Macedonia, seriously weakened since the death of Cassander (*q.v.*) in 297 B.C., and safeguarded Macedonian interests by keeping Greece divided without attempting to conquer the whole country. He encouraged the arts; in his literary circle poetry, history and philosophy were represented. He himself was considerably influenced by personal contact with the philosophers Menedemus of Eretria and Zeno, the founder of Stoicism.

See W. W. Tarn, *Antigonos Gonatas* (1913). (R. H. Si.)

ANTIGUA, an island of the Lesser Antilles in the Caribbean. With Barbuda and Redonda it forms a British colony and was one of the 12 territories comprising The West Indies federation (*q.v.*). Antigua lies at the southern end of the Leeward Islands chain, and has an area of 108 sq.mi. The coast line is intricate with many bays and headlands fringed with reefs and shoals; several inlets, including St. Johns, Parham and English Harbour, afford anchorage for shipping. The island is low and undulating but in the south a range of hills rises to 1,319 ft. at Boggy Peak. An absence of mountains and thorough deforestation distinguish Antigua from the other Leeward Islands. As there are no rivers and few springs, prolonged droughts occur despite a mean annual rainfall of about 44 in.

The Leeward Islands colony was defederated in 1956, and in 1958 Antigua joined The West Indies federation. The system of government is ministerial, and the executive council consists of four elected, one nominated and one official member, presided over by the administrator. In the federal parliament Antigua is represented by two members in the lower house and two in the senate.

The population of Antigua (1960) was 54,354 (including Barbuda), of which 21,396 lived in St. Johns, the capital city. There is chronic unemployment and underemployment, and, of a total of 9,500 wage earners about 4,000 are employed in the sugar industry, though numbers are higher during the harvesting season. The main products are sugar, cotton and molasses; in the late 1950s sugar constituted about 45% of the value of exports, with cotton, in second place, furnishing 20%. Exports in this period totaled about B.W.I. $7,000,000 and imports between B.W.I. $11,000,000 and $13,000,000. Tourism is an important industry, and Antigua has good hotels. The former naval base at English Harbour has been restored and is a favoured berth for yachts. Main imports consist of food, clothes, timber and nonedible oils. A number of shipping lines call at St. Johns and airlines provide regular services to Coolidge field in the north of the island. In the late 1950s government revenues and expenditures balanced out at slightly less than B.W.I. $9,000,000. Provisions for grant-in-aid are made by the British government. By the end of the development planning period in 1960, Antigua had received B.W.I. $6,123,200 since 1945.

Primary and post-primary education is compulsory at 34 government and 11 private schools. There are 7 secondary schools attended by 2,000 children, and a teachers' training college.

Antigua was discovered in 1493 by Christopher Columbus who named it after the church of Santa Maria la Antigua in Seville, Spain. It was colonized by English settlers in 1632 and remained a British possession, although raided by the French in 1666. In 1941 the United States obtained a base on a 99-year lease under the lend-lease agreement. This base was partially reactivated in 1955 in connection with the firing of long-range missiles.

Barbuda, formerly Dulcina, lies 25 mi. N. of Antigua. It is 62 sq.mi. in area and had a population of 1,145 in 1960. Barbuda is a coral island, flat and well-wooded, with highlands rising to 200 ft. in the northeast. Codrington, the only settlement, lies on a lagoon on the west of the island; an anchorage at The River, the nearest point to Antigua, is favoured by sloops. The inhabitants are fishermen, smugglers, farmers and charcoal burners. There is a government stock farm and the island has long been used as a game reserve.

Barbuda was colonized in 1628 and granted to the Codrington family in 1680. It reverted to the crown in the late 19th century. There is an Anglican church and primary school, and several chapels.

Redonda, an uninhabited rock, lies 34 mi. W.S.W. of Antigua. It rises sheer to a height of 1,000 ft. and is ½ sq.mi. in area. Phosphate of alumina (discovered in 1865) was worked there until 1916 with an annual output of about 7,000 tons.

See *Colonial Office List* (H.M.S.O., annually). (R. To.)

ANTIGUA (ANTIGUA GUATEMALA), a city in Sacatepéquez department, Guatemala, was capital of the former captaincy general and once the most important seat of Spanish colonial government between Mexico City and Lima, Peru. Pop. (1957 est.) 13,367. Founded as Santiago de los Caballeros (Ciudad Vieja) in 1527, it was destroyed by a torrent that swept down from the slopes of the volcano Agua. Antigua, which was constructed in 1542 near the site of Ciudad Vieja following this disaster, was demolished by an earthquake in 1773 and the capital was moved 15 mi. to the site of modern Guatemala City in the hope of avoiding further disasters; the previous seat of government became known as *la antigua capital* (the old capital), or Antigua.

The present city is noted chiefly for the ruins of colonial edifices that make it a museum of Spanish colonial history. On or near the central plaza, several of the principal buildings of the colonial capital still serve public functions: the palace of the captains general, the cathedral, the municipal palace and the University of San Carlos. Among the larger ruins of religious structures that dot the city are the churches and convents of San Francisco, Capuchinas, Compañia de Jesús and La Recolección. The church of La Merced survived the earthquake and is still in use. Several private dwellings of the colonial period have been restored, the most famous of which is the Wilson Popenoe house.

In the environs are San Juan del Obispo, restored countryseat of colonial churchmen; Ciudad Vieja; Indian villages such as San Antonio Aguas Calientes, noted for its quality weaving; and Santa María de Jesús, a town of palisaded compounds high on the slopes of Agua.

Antigua has several modern hotels situated in quiet, picturesque surroundings. The grandeur of its setting, at the base of towering volcanoes, and its benign climate make the city a favourite resort and residential site. A paved highway leads to Guatemala City.

(W. J. G.)

ANTIHISTAMINES are a group of drugs which reduce or prevent the physiological action of histamine (*q.v.*) by competing with it at the places in the body where it normally acts. True antihistamine drugs are competitive inhibitors of the action of histamine and have no clear-cut action in its absence. They act differently from drugs such as epinephrine (*see* ADRENALINE AND NORADRENALINE) which tend to act as antidotes to histamine by producing opposite physiological actions.

Medicinal use of antihistamines is based upon evidence that histamine causes many of the symptoms of various allergic disorders. Normally histamine is present in tissues in a bound, physiologically inactive form, and only under certain conditions in which it is released from the bound form does it exhibit toxicity. Therefore, in various allergic conditions, the symptoms which are relieved by the antihistamines are believed to be due to histamine which has been released from its bound form in the tissues.

The first specific antihistamine drug to be used therapeutically was Antergan (dimethylaminoethylbenzoyl-aniline), which was introduced in 1942 in France. Soon afterward a similar compound with lower toxicity, called Neo-Antergan, was developed in the same country. In 1945 Diphenhydramine, an ethanolamine derivative, was introduced in the United States, and thereafter numerous antihistamine drugs were developed. All of them have the same basic structure, which may be represented as follows:

$$R-X-\underset{|}{\overset{|}{C}}-\underset{|}{\overset{|}{C}}-N\Big<$$

The commonly used antihistamine drugs are derivatives of ethylenediamine, ethanolamine and propylamine, which have nitrogen, oxygen and carbon respectively for the X in the type formula shown above. Each has its special virtue: ethylenediamines generally are effective in lower doses; ethanolamines have the most powerful sedative actions; and propylamines exhibit lower toxicity and fewer side effects.

The antihistamine drugs inhibit or abolish many of the actions of histamine, including histamine-induced intestinal spasm, fall in blood pressure and increased capillary permeability. They are used most widely in the treatment of hay fever and other allergies. In general, they have been disappointing for the treatment of asthma, although in some cases they afford partial relief. Some but not all of the antihistamine drugs relieve the nausea and vertigo which occur in such conditions as motion sickness, early pregnancy and radiation sickness.

All the antihistamines have some toxic effects that are unrelated to their ability to antagonize histamine. The commonest untoward reactions are due to central nervous system depression; they include drowsiness, delirium and coma. Neuropsychiatric manifestations such as nightmares, confusion and mental depression may occur as well as headache, dryness of the mouth, dilated pupils and blurred vision. Respiratory failure, sometimes preceded by convulsions, follows the administration of a lethal dose.

(K. P. DU.)

ANTILEGOMENA (Gr. "contradicted," "disputed"), an epithet used by early Christian writers to denote books whose claim to be included in the New Testament canon was in doubt. As examples, Eusebius of Caesarea (4th century) lists the epistles of James and Jude, II Peter and II–III John.

ANTILIA (ANTILLA or ISLAND OF THE SEVEN CITIES; Port. ILHA DAS SETE CIDADES), a legendary island in the Atlantic ocean. It is marked in several 15th-century maps, being accompanied in most of them by smaller *insulae de novo repertae*, "newly discovered islands," Royllo, St. Atanagio and Tanmar. The Florentine Paolo Toscanelli, in letters to Columbus and the Portuguese court (1474), takes Antilia as the principal landmark for measuring the distance between Lisbon and the island of Cipango or Zipangu (Japan). According to Portuguese tradition, after the Moors had conquered Spain and Portugal, the island of Antilia or Septe Cidades was colonized by Christian refugees under the archbishop of Oporto and six bishops. Each leader founded and ruled a city, free from the disorders of less Utopian states. Later tradition localized Antilia in the largest of the Azores, St. Michael's. The legend may commemorate some imperfectly recorded discovery or may embody the idea of a western elysium like the Isles of the Blest, or Fortunate Islands.

ANTILLES comprise all the islands of the West Indies (*q.v.*) except the Bahamas. They are distinguished according to size, being divided into two major groups: the Greater Antilles include Cuba, Hispaniola (Haiti and Dominican Republic), Jamaica and Puerto Rico; the Lesser Antilles are the rest of the islands. The chain of islands curves for about 2,500 mi. in a broad arc from Florida to the northern coast of Venezuela. In general, the islands

are mountainous with tropical climate and vegetation.

The term dates traditionally from a period before the discovery of the new world, when it was called *Antilia* and referred to semi-mythical lands located somewhere west of Europe across the Atlantic. On medieval charts it was sometimes indicated as a continent or large island and sometimes as an archipelago. After discovery of the West Indies by Columbus, the Spanish term *Antillas* was commonly assigned to the new lands. (D. R. D.)

ANTILOCHUS, in Greek legend, son of Nestor, king of Pylos. One of the suitors of Helen, he accompanied his father to the Trojan War and distinguished himself as acting commander of the Pylians. He was a friend of Achilles, to whom he was commissioned to announce the death of Patroclus. When Nestor was attacked by Memnon, he saved his father's life at the sacrifice of his own, thus fulfilling the oracle that had bidden him "beware of an Ethiopian." According to late accounts, he was slain by Hector or by Paris in the temple of the Thymbraean Apollo together with Achilles.

ANTIMACHUS (fl. *c.* 400 B.C.), of Colophon or Claros, Greek poet and grammarian, wrote a lengthy epic *Thebais*, an account of the expedition of the Seven Against Thebes and the war of the Epigoni. He thus became the founder of "learned" epic poetry and the forerunner of the Alexandrian school, whose canon allotted him the next place to Homer. He also wrote an elegiac poem *Lyde*, so called after his mistress. These poems, though not popular, were praised by Plato. He also prepared a critical recension of the Homeric poems (mentioned 12 times in the Venetian scholia).

See C. B. Wyss, *Antimachi Colophonii Reliquiae* (1936); T. Bergk, *Poetae Lyrici Graeci*, various editions (1843–1915).

ANTIMASONIC PARTY, a U.S. political organization influential between 1827 and 1836. The Antimasonic movement was touched off in western New York state by the mysterious disappearance of William Morgan of Batavia, N.Y., a Freemason and itinerant worker with some intellectual doubts concerning the Order of the Masons. Morgan had prepared for publication a book, *Illustrations of Masonry*, revealing the order's secrets. Charged with stealing and indebtedness, apparently as a pretext for seizing and arraigning him, Morgan was committed in Sept. 1826 to an Ontario county, N.Y., jail and was reportedly kidnapped shortly after his release. His ultimate fate was never known; the opinion was widely held that he had been murdered. When Masonic leaders refused to co-operate in the excited and prolonged search for clues and culprits, the press, churches, temperance and antislavery elements joined in condemning all Freemasonry as responsible for the "murder." The democratic and libertarian spirit uniting these elements attracted the support of many farmers and workers, a political fact not lost upon the leaders of the declining National Republican party in the state. Although not yet openly identified with the National Republicans, Thurlow Weed (*q.v.*), publisher of the *Rochester* (N.Y.) *Telegraph* and subsequently of the *Anti-Masonic Enquirer* led the press assault on Freemasonry, editorially endorsing Antimasonic candidates for state offices in the fall campaign of 1827. When 15 of these candidates were elected to the state assembly, the Antimasonic party came into being. During 1828 New York members held their first state party convention and in Feb. 1829 held a second. National conventions met at Philadelphia on Sept. 11, 1830, and at Baltimore Sept. 1831, the latter to nominate candidates for president and vice-president.

Between 1828 and 1831 the Antimasonic movement had spread across the middle Atlantic states into New England, usually through church, temperance and antislavery channels. As it developed, however, New England Antimasonic collaboration in elections was with Jacksonian Democrats, rather than National Republicans as in New York.

The Antimasonic national nominating convention of 1831 in Baltimore was the first of its kind in U.S. political history. Thirteen states were represented by 116 Antimasons. The convention required a special three-fourths majority to nominate, establishing the precedent for the two-thirds rule used by the Democrats in subsequent national conventions for more than a century. William Wirt of Maryland, attorney general under James Monroe and John Quincy Adams, was nominated for president, although substantial elements in the convention favoured endorsing Henry Clay, about to become the National Republican nominee. The Antimasonry issue had by this time, however, become secondary to internal improvement and the protective tariff; Wirt himself was a Freemason.

The Antimasonic party's achievements in national elections were few. In the presidential contest of 1832 it carried only Vermont. The party at the same time won a large number of seats in the 23rd congress (1833–1835), but few thereafter. Nonetheless, its influence lingered on in other ways. Its national convention system was followed in 1831 and 1832 by the National Republicans and the Jacksonian Democrats, and subsequently by the present major U.S. political parties. Further, several of the party's prominent leaders became founders of the national Whig and Democratic parties. *See* also FREEMASONRY.

(R. M. G.)

ANTIMATTER. An atom of ordinary matter is composed of a nucleus of positively charged protons and uncharged neutrons that is surrounded by a cloud of orbiting, negatively charged electrons (*see* ATOM). In 1928, the existence of an elementary particle equal in mass to the electron but bearing a positive electric charge was foreseen by P. A. M. Dirac in his relativistic quantum theory (*see* ELECTRON; QUANTUM MECHANICS). This particle, called a positron, was discovered by C. D. Anderson in 1932 in studies of cosmic-ray interactions observed in a Wilson cloud chamber. In 1955 Emilio Segrè, Owen Chamberlain and their co-workers at the University of California discovered the antiproton, an elementary particle having the same mass as the proton (*q.v.*) but carrying a negative charge. In 1956 these men and others at the University of California confirmed the existence of the antineutron, a particle identical to the neutron except that its magnetic properties are reversed in sign. Atoms composed of nuclei of antiprotons and antineutrons with orbiting positrons surrounding these nuclei would constitute antimatter.

Antimatter would be completely stable if isolated from ordinary matter; however, if an atom of antimatter were to collide with an atom of ordinary matter, the two would immediately undergo mutual and complete annihilation, with π mesons and other unstable particles being created. Within a fraction of a second, all of these unstable particles would be spontaneously transformed into radiant energy—gamma rays (high-frequency electromagnetic radiation) and stable, massless particles called neutrinos. For comparison, it may be noted that in the processes of nuclear fission, used in the so-called atomic bomb, and nuclear fusion, used in the hydrogen bomb, only a small percentage of the reacting mass is converted into energy (*see* ATOMIC ENERGY).

Although antimatter does not exist in a stable form on earth, it has been speculated that distant galaxies in the universe are composed entirely of antimatter. A careful search for indications of positrons and antimatter nuclei in the primary cosmic rays entering the earth's atmosphere from outer space has been made, but as of the early 1960s this search had been unsuccessful; it has been proved that if antimatter is indeed contained in primary cosmic rays, it exists only in extremely small amounts (*see* COSMIC RAYS). The principal argument against it lies in the absence in cosmic rays of the expected gamma radiation that would be produced in profusion by the mutual annihilation of matter and antimatter.

The idea that antimatter exists in profuse amounts elsewhere in the universe has more than an aesthetic appeal. A corresponding antiparticle has been discovered for most of the known types of "ordinary" particles, as explained in PARTICLES, ELEMENTARY. Furthermore, material particles (electrons and positrons) have been created from electromagnetic radiation (gamma rays) in the

presence of matter in terrestrial laboratories. This process, known as "pair production," also results naturally from certain cosmic-ray interactions. However, whenever an electron is created from radiation, its antiparticle, *i.e.*, the positron, is simultaneously created. If the not illogical concept of symmetry in creation is assumed, then for every elementary particle that has been created there must exist somewhere in the universe its antiparticle, so that in the universe as a whole the total amounts of ordinary matter and antimatter are equal. Segrè has stated: "When God made the universe—if you assume he did—is there any reason to believe he preferred matter to antimatter?"

If all material matter in the world were suddenly replaced by antimatter, such a world would be essentially undistinguishable from the present world. All the laws of physics would remain the same except for certain laws governing the so-called "weak" interactions of the elementary particles, which do not observe symmetry.

The 30-Bev particle accelerator in the CERN laboratory near Geneva, Switzerland, has produced beams of antiprotons, but whether antimatter will someday be created in profusion, and whether it can ever be utilized to provide useful energy or to produce an "antimatter bomb," remain challenging questions for the future.

ANTIMETABOLITES. An antimetabolite is a specific antagonist of a particular substance in metabolic reactions of living organisms. Various food substances (nutrients) or essential substances produced from nutrients (essential metabolites) can be prevented from performing their biochemical roles by their specific antagonists. Substances for which such metabolic antagonists are known include vitamins, amino acids (which are essential for protein synthesis), certain hormones, purines (*qq.v.*) and pyrimidines (which among other functions are also essential for the synthesis of the genetic material of cells) and certain carbohydrates (*q.v.*).

Often a compound structurally related to a nutrient or essential metabolite is one of its specific metabolic antagonists. For example, the sulfa drugs (*see* SULFONAMIDES) are metabolic antagonists of para-aminobenzoic acid (PABA), a vitaminlike nutrient, or essential metabolite, for many bacteria. The similarities of the chemical structures are demonstrated below:

Sulfanilamide

Para-aminobenzoic acid (PABA)

The sulfa drugs are effective chemotherapeutically in the treatment of certain bacterial infections because they disrupt bacterial metabolism. Specifically, the sulfa drugs prevent bacterial utilization of PABA for folic acid synthesis. It appears that the bacteria cannot "discriminate" between these structural analogues, and the antagonistic sulfa molecule is "mistaken" for the essential PABA molecule. The functions of the animal host, which does not synthesize its own folic acid, are not affected by sulfa drugs.

The requirements of a growing cell differ from those of a nongrowing cell; hence, certain antimetabolites can affect the growth of rapidly dividing cells without appreciably damaging nongrowing cells, and some antimetabolites have thus found limited use as antitumour agents. Antagonisms are of prime importance in pharmacological drugs such as the antihistamines (*q.v.*). Certain natural antibiotics are known to be antimetabolites; in fact, most antibiotics may ultimately be found to exert their biological effects in this manner. Antimetabolites are also useful in the study of the biochemistry of living organisms.

An antimetabolite exerts its effect by interacting with a particular biological catalyst (an enzyme, *q.v.*) in such a manner as to prevent the enzyme from promoting a specific biochemical reaction. This mode of action is known as enzyme inhibition, and the antimetabolite is an inhibitor of enzymic catalysis. An enzyme exerts its catalytic effect by interacting with a specific substance, which is called its substrate, to form a complex; the complex undergoes further chemical change so that it finally dissociates into a specific product and the free enzyme which can again transform more of the substrate. An analogous compound, structurally related to the substrate, can frequently interact with the enzyme at the same site as the substrate to form an enzyme-inhibitor complex which is incapable of forming the normal product of the enzyme system. This mode of action which represents that of most antimetabolites is indicated by the following equations:

$$\text{enzyme} + \text{substrate} \rightleftarrows \begin{array}{c}\text{enzyme-substrate}\\ \text{complex}\end{array} \longrightarrow \text{product} + \text{enzyme}$$

$$\text{enzyme} + \text{inhibitor} \rightleftarrows \text{enzyme-inhibitor complex}$$

If the substrate and inhibitor both compete for the same site on the enzyme to form a complex in a reversible manner, the inhibition is competitive, and the ratio of the concentration of inhibitor to that of the substrate determines approximately the degree of inhibition rather than the absolute concentration of inhibitor. This ratio is termed the inhibition index for a defined degree of inhibition. An example of an inhibitor structurally related to the substrate is malonic acid ($HOOC—CH_2—COOH$), which interacts with the enzyme succinic acid dehydrogenase to prevent succinic acid ($HOOC—CH_2—CH_2—COOH$) from complexing with the enzyme and undergoing dehydrogenation to fumaric acid ($HOOC—CH{=}CH—COOH$). Such examples were known before it was generally realized that analogues of metabolites could exert inhibitory effects of this type within living organisms.

An inhibitor may interact at a site different from that of the substrate so that an inactive complex of enzyme-substrate-inhibitor is formed. Such an inhibition is noncompetitive, and the inhibitor is capable of preventing enzyme activity regardless of substrate concentration. Occasionally an inhibitor may interact only with the enzyme-substrate complex and not with free enzyme, resulting in an inhibition which is termed uncompetitive.

By specifically blocking the utilization of a particular nutrient or essential metabolite with an antimetabolite and studying the effects of other nutrients and essential metabolites upon the inhibition, one can determine the sequences of biochemical reactions in living organisms. This method, termed inhibition analysis, has been particularly useful with microorganisms in developing assay methods for the detection necessary for the isolation of new vitamins and growth-promoting factors, in elucidating the metabolic roles of vitamins and vitaminlike substances and in discovering new metabolic interrelationships and intermediates.

See D. Woolley, *A Study of Antimetabolites* (1952). (W. SH.)

ANTIMONY is a bright, silvery-white, metallic element having a hard, brittle crystalline structure. It occurs in nature primarily as the mineral stibnite (*q.v.*), and is employed chiefly to impart hardness to lead alloys used in storage batteries and other products. Its many peculiar characteristics make it valuable as a component of flameproofing chemicals, ceramic enamels, compound semiconductors, smoke generators, explosives and medicines. This article deals with the history of antimony, and its physical and chemical properties, uses, occurrence and production.

HISTORY

Man's use of antimony predates the Christian era by many thousand years. A Chaldean vase dated approximately 4000 B.C. attests that these ancient people knew the art of winning antimony from its ores. In St. Jerome's translation of the Bible, Jezebel, the wicked wife of Ahab, is reported to have painted her eyes with stibium, a name that has given antimony its chemical symbol, Sb. Egyptian women used cosmetics of antimony to beautify their faces, and water from Egyptian wells was often borne in antimony vessels. Pliny the Elder (1st century, A.D.) gave an interesting description of a stibnite occurrence in a silver mine. "... There are two kinds of it, male and female, the female being most desirable, more radiant, smoother and brighter." With his gift for picturesque inaccuracy, Pliny also described a process for reduction of the ore. He cautioned that improper care in roasting the stibnite with manure and quenching it with milk would result in its turning to lead.

In *The Triumphant Chariot of Antimony* (1604; Eng. trans., 1660; 1661; ed. by E. A. Waite, 1893), attributed to Basil Valentine (in alchemy signifying "valiant king") who was supposed to have been a 15th century German monk, the author (Johann

Thölde), an early and enthusiastic investigator of the properties of antimony, noted the ability of antimony to free gold from its impurities and concluded it had a similar effect on man: ". . . Let men know that antimony purgeth gold and frees it from all foreign matter, but also by an innate power effects the same in men and beasts." According to this belief cattle were often fed antimony to fatten them. Monks reportedly used the same method to avoid the effects of fasting, often being fatally poisoned. Some speculators, therefore, attribute the name "antimony" to the combination of the Greek *anti*, "against," and *monos*, "one who dwells alone"—a monk. A probably more accurate interpretation suggested by a lexicographer is *antimonos*, "a metal seldom found alone."

PHYSICAL AND CHEMICAL PROPERTIES

The atomic weight of antimony is 121.75, and the atomic number is 51. Stable isotopes are 121 and 123; radioactive ones are 120, 122, 124, 125, 127, 129, and 132. Antimony is above bismuth and below arsenic in main Group V of the periodic table (*see* PERIODIC LAW). It has principal valences of 3 and 5.

Antimony forms many binary intermetallic compounds, some of which have useful electrical semiconducting qualities. Combinations of elements in Group III and Group V in many instances exhibit characteristics quite similar to single elements of Group IV. For example, aluminum-antimony responds electrically very much like silicon, a metal highly valued for its transistor and rectifier qualities. Aluminum, gallium, and indium unite with antimony to form compound face-centred cubic crystals that resemble the simple structures of diamond, silicon, and germanium (*qq.v.*). The energy gaps between saturated and conducting bands of these III–V compounds range from 0.40 electron volts for indium-antimony to 1.55 ev for aluminum-antimony, a range of values that encompasses the activation energies of all popular semiconductors.

Some Properties of Antimony

Chemical symbol	Sb
Crystal system	hexagonal
Specific gravity at 20° C.	6.62
Tensile strength, p.s.i.	1560
Hardness (Mohs' scale)	3 – 3.5
Coefficient of linear expansion at 20° C.	10.9×10^{-6}
Melting point	630.5° C.
Boiling point	1380° C.
Heat of fusion, cal./g. atom	4,780
Heat of vaporization, cal./g. atom	45,400
Specific heat, cal./g./°C.	0.0493
Vapour pressure of liquid, at 1,075° C.	54 mm.
Thermal conductivity, cal./cm.²/cm./° C./sec.	0.0444
Electrical resistivity, microhm-cm. at 20° C.	41.7
Specific magnetic susceptibility, at 20° C.	0.82×10^{-6}

Antimony exists in many allotropic forms, gray antimony being the most common and stable one. The properties of gray antimony are shown in the accompanying table. Electrolysis of an antimony trichloride solution produces an explosive form of the metal on a platinum foil cathode at the expense of a gray antimony anode. Friction causes the cathode metal to detonate loudly, evolving light and heat. Black antimony, another unstable form, is produced by rapid cooling of the metal vapour. The resulting black powder is quite active chemically and is subject to spontaneous combustion. It slowly reverts to gray antimony, but if heated to 400° C. the change is instantaneous.

Antimony is oxidized but slightly under atmospheric conditions. When heated in air, however, it burns with a bright bluish flame yielding Sb_2O_3 (or Sb_2O_4). Nitric acid also oxidizes the metal, forming the trioxide.

Antimony is amphoteric; that is, its hydroxide acts either as a base, $Sb(OH)_3$, or as an acid, H_3SbO_3.

Solution of the trioxide in hydrochloric acid yields a trichloride of large soft crystals known as butter of antimony that hydrolyzes and reacts with water to form the insoluble oxychloride.

Antimony trisulfide, Sb_2S_3, is readily prepared by heating stoichiometric proportions (*i.e.*, the combining weights) of the two powdered ingredients in a mortar. The beautiful orange-red sulfide pigment is precipitated from an antimony trichloride solution by addition of hydrogen sulfide gas. Dissolving the trisulfide in yellow ammonium sulfide produces a soluble ammonium thioantimonate solution that, when treated with acid, yields an orange precipitate of antimony pentasulfide, Sb_2S_5.

Antimony combines directly with the halogens (*q.v.*) to form compounds of type SbX_3 and SbX_5. Like other salts of antimony, halides are partly hydrolyzed by water, forming basic salts.

USES

Antimony in its pure state has essentially no uses; yet, in physical and chemical combination with other substances it is one of man's most useful metals. Approximately one-half of the yearly world supply is consumed in alloy fabrication. Chemical uses in fireworks, pottery, glass, paints, plastics, rubber and fabrics account for one-half the industrial consumption of antimony.

A Hardening Agent.—Even added in small quantities, antimony imparts strength and hardness to other metals, particularly lead. The largest single use of antimony is in the manufacture of automobile storage batteries. From 4% to 11% antimony added to lead yields strong, corrosive resistant grids and terminals. Other items in which antimony is used to harden alloys and/or inhibit chemical decay are pumps, tank linings, roofing sheets, plumbing fixtures and pipes, cable sheaths, foil and bullets.

Antifriction Bearings.—A series of alloys called babbitt or "white metal" that are indispensable to a machine-age civilization contain 5% to 18% antimony as an essential component. Other constituents of these so-called antifriction alloys are tin, lead, and copper. In the tin-base group, SnSb is present as hard discrete cubes in a matrix of $SnCu_3$, needle-shaped, relatively soft crystals. The antifriction quality of the alloy is obtained from the force-absorbing features of such a hard-soft binary combination. (*See* BEARING METALS.) A similar, though less pronounced, effect is obtained in the lead-base babbitt wherein hard SnSb is imbedded in lead. The antimony content of lead-base antifriction alloys ranges from 10% to 18% (*see* also BABBITT'S METAL).

Type Metal.—Lead containing 13% to 30% antimony and minor amounts of tin is used in linotype and stereotype machines to produce accurate cast printing type. (*See* TYPE METAL.) Antimony increases the hardness, lowers the melting point of the lead, and imparts sharp definition to the type. Maximum fusibility is obtained from the near eutectic mixture (that is, having the lowest melting point possible for the constituents) of 13 Sb, 85 Pb, 2 Sn, whereas maximum precision in duplication of type requires large portions of antimony at the expense of the lead content.

Decorative Castings.—Low melting point, precision duplication, durability, metallic beauty, and economy make antimonial alloys desirable materials from which statuettes, candlesticks and other useful and decorative objects are cast. Britannia metal (*q.v.*), a silvery white alloy from which hollow ware and tableware are made, contains 5% to 10% antimony dissolved in tin. Varieties of pewter contain a maximum of 7% antimony.

Solder.—The ability of antimony to form low-melting-point eutectics and increase the hardness of alloys makes it useful in solders.

Semiconductors.—Aluminum-antimony, though having an energy gap too great for ordinary rectifier and transistor applications, has a redeeming feature—its electrical properties vary widely with even minute changes in the amount of atomic imperfections within the crystal lattice. Control processing produces both P- and N-type crystals (*see* TRANSISTOR) whose electrical resistivity, in experimental tests, has been varied by a factor of 500,000 and rectification ratios near 10,000 have been achieved. Its behaviour at elevated temperatures has suggested possible uses in high-temperature electronic devices. Aluminum-antimony has attracted interest to its photoconductive and photogenerative effects. Contact devices can be produced to act as electrical switches on exposure to light and can directly convert light to electrical energy.

Electrical resistance elements of indium-antimony are extremely sensitive to changes in an applied magnetic field. When an indium-antimony current-carrying conductor is placed in a properly oriented magnetic field it is polarized transverse to the current flow.

By suitable electrocoupling a transverse secondary current is generated, giving rise to a flux field that opposes current flow in the primary circuit. The resulting effective resistance is proportional to the applied magnetic field intensity. Sensitivity and strength of the response are such that many uses are possible in control circuits.

Flameproofing.—Fabrics are made fire resistant by treatment with a solution of antimony trioxide or trichloride in an organic solvent. Flames accompanying initial combustion are extinguished by chemical reactants released as the impregnating solution is heated. Antimony oxide (Sb_2O_3) is used in the paint and plastics industries both as a pigment and fire-retarding agent. In wartime the premium placed on fire prevention and control greatly expands the use of antimonial flame retardants.

Paints.—Finely powdered antimony trioxide is a dense white pigment used as a constituent of paints. It is also used as an opacifying agent in white ceramic enamels imparting a blister-free, brilliant finish. "Antimony black" is precipitated, finely subdivided, metallic antimony used as a bronzing agent for metals and plaster casts. Antimony vermilion is a pigment of red trisulfide precipitated from an antimonial solution by hydrogen sulfide gas. The "antimony yellow" is produced by controlled oxidation of the sulfide. Oranges, blues and greens are produced by blending with other mineral pigments.

Ammunition.—Antimony sulfide in the form of liquated crudum (see *Production*, below) is a component of ammunition primers and of military pyrotechnics such as smoke generators, visual range-finding shells and tracer bullets. A small amount of sulfide is also used in friction matches.

Rubber Industry.—Antimony pentasulfide is a commonly used vulcanizing agent.

Textile Industry.—In the dyeing of fabrics, tartar emetic and antimonine are used as mordants. Chlorinated paraffin, antimony oxide and calcium carbonate are combined as a "finishing" additive to textile fibres. The role of antimony oxide is filtering out fibre-destroying, ultraviolet wave lengths of normal light.

Glass Industry.—Antimony oxide, like silica, is a glass-forming substance. Mixed with suitable stabilizers, antimony-oxide glass exhibits superior light transmitting ability near the infrared end of the spectrum. With sufficient colouring additives glass can be made opaque to all visible light except long wave infrared rays.

Medicine.—Though a number of organic antimony compounds have been used successfully in the treatment of parasitic diseases, antimony is highly toxic to the human body giving rise to symptoms similar to those produced by arsenic. It is an irritant internally and externally and affects the heartbeat, respiration and nervous systems. Tartar emetic (potassium antimonyl tartrate) has been used as a nauseant and expectorant.

OCCURRENCE

The mineral stibnite, Sb_2S_3, is the primary ore mineral of antimony. It (with its oxidized equivalents) is found in fissure veins in the western United States, Mexico, Bolivia, Yugoslavia, Turkey, Algeria, Morocco, Union of South Africa and China. The deposits are hydrothermal in origin; that is, the mineralizing fluids were generated during the process of emplacement of igneous intrusive rock masses. The more common genetic associations are with granites, granodiorites and monzonites. The mineralogy of the veins and their almost invariable shallow depth suggest a low temperature of formation at near-surface positions, possibly related to configuration of the water table at time of deposition. Typically, stibnite (*q.v.*) deposits are small and discontinuous.

Antimony also occurs as a minor constituent of other metalliferous ores. In the process of refining the major metal values, an antimony-enriched product is segregated. Often it appears in the bullion at lead refineries and is redeemed as antimony metal, antimonial lead or commercial grade antimony oxide. Because the antimony thus redeemed has no economic value until it is incidently concentrated by many intermediate processes, the antimony content of the ores from which the bullion was derived is obscured.

There are few deposits of antimony wherein ore is developed in advance of current mining requirements. World reserves therefore are necessarily based on known correlative data, such as historical production levels and geologic patterns of occurrence. China is the dominant possessor of ore reserves. Estimates range from 2,000,000 to 5,700,000 tons of contained antimony—a quantity that dwarfs the reserves of any other country. In the second half of the 20th century the bureau of mines and the geological survey, U.S. department of the interior, estimated world reserves, excluding China, at approximately 2,000,000 tons. Bolivia was estimated to have 400,000 tons; Mexico, U. of S.Af., U.S.S.R., each 250,000 tons; U.S., Yugoslavia, Australia, Algeria-Morocco, 100,000 tons each. Canada, Peru, Turkey, Czechoslovakia (collectively) had 225,000 tons.

PRODUCTION

Metallurgy.—Antimony sulfide may be separated from the associated rock gangue by liquation. The ore is heated above the fusion point, and maintained below the boiling temperature, of stibnite. The resulting molten sulfide seeps by gravity through the hot mass of ore and is collected and cooled in a lower container. The rather pure liquated sulfide is referred to as crudum or needle antimony and is used directly in many industrial processes. That which is not sold as crudum is roasted to produce the volatile antimony trioxide which is recovered from the condensed roaster gases. The portion of the oxide that is not directly marketed is reduced to metal (regulus) by smelting in small reverberatory furnaces with ground charcoal and suitable fluxes. Antimony sulfide may be roasted and smelted directly to metal in a blast furnace by a method quite similar to lead smelting.

Antimony metal, antimony oxide and antimonial lead are often recovered as a byproduct at lead refineries in processing lead bullion that contains antimony as an impurity. In the method called softening, air is bubbled into a bath of molten lead at about 850° C.; antimony and arsenic impurities are selectively oxidized in preference to the lead and form oxides that float to the surface of the bath and can be skimmed off. In the less widely used electrolytic method, lead anodes are electrolyzed in a fluosilicic acid bath to yield high purity lead cathodes. The anode residue contains the metallic impurities with which the lead was associated. Often the antimony content is sufficiently high to permit economic recovery. World supply of antimony is augmented by a large secondary production of antimonial alloys from antimony-containing scrap metal. Old automobile battery grids is the major source material on which secondary plants depend.

Mine Production.—World mine output of antimony is quite responsive to fluctuations in the business cycle. In 1931, at the depth of the worldwide economic depression, mine production fell to 17,000 short tons. The war-stimulated industrial level of 1943 evoked a mine output of nearly 60,000 short tons. The highest production was in 1951 during the Korean conflict when recorded world mine output rose to 70,000 short tons. Prior to 1935 China supplied two-thirds of the annual world total antimony production, but with progress of the Chinese-Japanese War the centre of principal production shifted to the Americas. The United States, Mexico and Bolivia were leading world suppliers of antimony during and immediately after World War II. In the years immediately following the Korean war, the mines of China and the Republic of South Africa became the dominant contributors of antimony.

ANTIN, MARY (1881–1949), Russian-born U.S. author of the autobiography *The Promised Land* (1912), an account of the experiences of European Jews and the contrast with life in the United States. Born in Polotzk, Russia, in 1881, Mary Antin emigrated to the United States in 1894 and attended Teachers college of Columbia university and Barnard college, New York city, 1901–04.

She wrote about her voyage to the United States in her first book, *From Polotzk to Boston* (Eng. trans., 1899), originally writ-

ten in Yiddish. After the publication of *The Promised Land*, which first appeared as a serial in the *Atlantic Monthly* and won wide acclaim, she toured the United States for a number of years as a lecturer.

Her third book on immigrants, *They Who Knock at Our Gates*, was published in 1914. She was later a resident worker at Gould farm, a social service community at Great Barrington, Mass. In 1901 she was married to Amadeus Grabau, U.S. paleontologist and professor at Columbia university. She died at Suffern, N.Y., on May 15, 1949.

ANTINOMIANISM (*anti*, "against," and *nomos*, "law"), first attributed to Martin Luther's collaborator Johann Agricola (*q.v.*), a doctrine according to which Christians are freed by grace from the necessity of obeying the Mosaic Law. The Antinomians rejected the very notion of obedience as legalistic; to them the good life flowed from the inner working of the Holy Spirit. In this they could and did appeal not only to Luther but also to Paul and Augustine.

Antinomianism appeared also in the Reformed branch of Protestantism. John Calvin wrote against "the sect of Libertines who call themselves Spiritual." The left-wing Anabaptists (*q.v.*) were accused of Antinomianism, not only for theological reasons but also because they opposed the co-operation of church and state, which was considered necessary for law and order. For similar reasons, in the first half of the 17th century, Separatists, Familists, Ranters and Independents in England were called Antinomians by theologians of the established churches. In New England, Anne Hutchinson was accused of Antinomianism when she said that the churches were preaching "the covenant of works." The Wesleyan movement at the end of the 18th century produced its own Antinomians who claimed an inner experience and a "new life" which they considered as the true source of good works. Since in Jesus Christ and by the working of the Spirit in their hearts they were saved from sin, they sought to live in purity without the benefit of the Law. However, they fell into legalisms of their own.

Antinomianism grew out of Protestant controversies on the Law and the Gospel, but it was not unknown previously. In the early church there were those who said, "Let us sin that grace may abound" (*see* Rom. vi, 15 ff.). To some Gnostic heretics, freedom from the Law meant freedom for licence. "The spiritual," being above vulgar morality, were prone to indulge the flesh and its lusts. However, Antinomianism in the ancient and medieval church, as represented by Montanists and Marcionites (*q.v.*), and later by the Spiritual Franciscans and sundry popular pietistic movements, frequently was a protest against worldliness, legalism and clericalism in Christendom.

ANTINOMY, a contradiction, real or apparent, between two principles or conclusions, both of which seem equally justified. An approximate synonym is paradox. Kant used the word in elaborating his doctrine that "pure Reason" generates contradictions in seeking to grasp the "unconditioned." He offered "proofs" of the proposition: (1) that the universe had a beginning and is of finite extent (the thesis)—and also of a contrary proposition (the antithesis). Similarly for the three propositions: (2) that every complex substance consists of simple parts; (3) that not every phenomenon has a sufficient "natural" cause, *i.e.*, that there is freedom in the universe; (4) that there exists a necessary Being, either within or outside the universe. Kant used the first two of these antinomies to infer that space and time are subjective. He resolved all four by a distinction between phenomena and noumena (intelligible things).

A series of logical antinomies (also known as logical paradoxes) have played an important part in the development of modern logic. One of the best known and least technical of these is the paradox of the class of all classes that are not members of themselves (published by Bertrand Russell in 1903).

The line of argument runs: Given any class of things, c for example, either c is a member of itself, or else not—one or the other, but not both. (Thus if c is the class of men, c is not a member of c, since the class of men is not a man; while if c is the class of all classes, c is a member of c, since the class of all classes is itself a class.) Let a class that is not a member of itself be called an exclusive class. Consider the class of all exclusive classes, K for example. The object is to determine whether K itself is exclusive or not. If K is exclusive, it has to be a member of K (since K was defined as the class of all exclusive classes). But exclusive means: not a member of itself. So K has to be not exclusive. Suppose, then, that K is not exclusive. This means it is a member of itself. But all the members of K are exclusive classes. Hence, K is exclusive. It would seem, then, that K can be neither exclusive nor nonexclusive, though every class must be one or the other.

In this way Russell's paradox derives a contradiction from definitions and modes of reasoning previously accepted as correct in both logic and mathematics. Much ingenuity has been expended in finding flaws in the argument, or in making compensatory revisions in logical doctrine. Among the best-known methods are the so-called simple theory of types (a modification of Russell's own solution) and certain types of axiomatic set theory (introduced by Ernst Zermelo, and subsequently improved by many writers). Many similar logical paradoxes have been formulated. Among those having direct bearing upon the foundations of mathematics are Cesare Burali-Forti's paradox of the greatest ordinal number (published 1897) and the paradox of the greatest cardinal number (published by Russell, 1903). *See* also Semantics in Logic, and Logic, History of, for the closely related semantical paradoxes.

ANTINOÜS, a beautiful youth of Claudiopolis in Bithynia, was the favourite of the emperor Hadrian, whom he accompanied on his journeys. During one of these he was drowned in the Nile (A.D. 130) near Besa. Hadrian said his death was accidental, but rumour had it that he had voluntarily sacrificed his life to fulfill a prophecy that death was soon to affect the emperor closely. Hadrian deified him after his death, and temples were built for his worship all over the Roman world, particularly in Bithynia, at Mantinea in Arcadia (which claimed to be the mother city of the Bithynians) and at Athens. The city of Antinoöpolis was founded (Oct. 30, 130) at the place of his death, partly in his honour, but probably with the further object of strengthening Hellenism in Middle Egypt.

A great number of statues, busts, gems and coins survive depicting Antinoüs as an ideal type of youthful beauty, often with the attributes of some appropriate god. Notable examples are in the Vatican, the Louvre and the Villa Albani at Rome.

ANTIOCH (Antakya in southeastern Turkey), sometimes called "Antioch near Daphne" or "Antioch on the Orontes" to distinguish it from other Antiochs, was once considered the third city (Antiochia) of the Roman empire in size and importance. It was disposed on the left bank of the virtually unnavigable Orontes river (Asi Nehri) at the point where, having made a sharp bend, it breaks out of the Syrian rift valley toward the Mediterranean through a defile about 16 mi. in length. The route down the valley led no farther than the river's mouth, movement along the coast being blocked by the spurs of Mt. Pieria and Mt. Cassius. But Antioch also controlled the passage of the coastal ranges 20 mi. to the north through the Syrian Gates (the Belen or Bailan pass). From there a highway went westward through Cilicia and across Asia Minor, while to the east the commercial and military route (through Aleppo) turned the flank of the Syrian desert and was the regular approach to the Mediterranean from the direction of Mesopotamia. To the south extended the populous valley of Coele-Syria (Lebanon), rich in cereals and fruit. A continuation of the same depression to the northeast opened access to the high valleys of the upper Euphrates and the plateaus of Armenia.

HISTORY

Classical Antioch.—Antioch was founded at the end of the 4th century B.C. by Seleucus I Nicator together with the coastal town of Seleucia Pieria, which served as its port. He named it after his father, the Macedonian general Antiochus, and laid it out on a simple squared plan between the river and the slopes of Mt. Silpius. All settlers of whatever race were given equal privileges of citizenship, and the population was divided into 18 constituencies which elected a common council. A new walled quarter, containing many fine temples, was added on the east side by the founder's son Antiochus I Soter. Seleucus II Callinicus constructed a third section on an island in the river; there the intersection of the two main streets was marked by a magnificent four-faced arch, and the extension was connected with the main city to the south by five bridges. About 170 B.C. Antiochus IV Epiphanes constructed a fourth quarter of Antioch, which thus gained the title of "Tetrapolis" (the "four-citied").

In 64 B.C. Syria became a Roman province, and more temples, theatres, baths and aqueducts were added to Antioch. Unlike Rome, Constantinople, Athens and Alexandria, cities of comparable size under the Roman empire, Antioch has contracted appreciably since the time of its early prosperity. Despite this, remarkably little of the ancient metropolis can now be seen. The scale and architecture of the bastions and wall-walks on the summit and slopes of Mt. Silpius can still be appreciated, and the superstructure of the famous Iron Gate, where the perimeter wall crossed a ravine of the mountain, and parts of an aqueduct leading from the direction of Daphne are still substantially intact. But between the lower hill slopes and the river the ancient city has been buried beneath a thick deposit of alluvium, probably occasioned by some change in the slope of the river bed following an earthquake. The topography of the lower part of the city has been altered, and no trace of the island where Seleucus II Callinicus added his suburb can now be descried. Excavations in the olive groves on the lower slopes of the citadel, where the overlying deposit is only moderately thick, yielded numerous mosaic pavements.

In imperial Roman times Antioch was the military base for operations against the Persians in Mesopotamia. From Antioch many orientals migrated to Rome, so that the satirist Juvenal complained that the Orontes had become a tributary of the Tiber. The city was famous at an early date as a centre of Christianity, but at the same time notorious for the profligacy of its pagan population. It underwent several substantial reconstructions after being devastated by earthquakes or overrun by invaders. The Persian king Shapur I took the place by surprise in A.D. 260, and it was severely shaken by an earthquake during the reign of Constantine I. Even so, St. John Chrysostom estimated the number of its inhabitants in the 4th century A.D. as 200,000, without reckoning children and slaves. The city, however, never fully recovered

ANTIOCH, SITUATED ON THE LEFT BANK OF THE ORONTES RIVER

from the double disaster of the great earthquake of 526, which is said to have killed 250,000 people, and its sack by Khosrau I in 540.

Medieval Antioch.—Arab armies took Antioch in A.D. 636, and though the Byzantines recaptured it in 969, it fell once more into Muslim hands when the Seljuk Turks overran it in 1084. After an ineffectual siege of more than seven months, a force of 300,000 crusaders stormed the city with the help of a traitor in 1098. Though in possession, they were quickly overtaken by disease and famine, and were only inspired to drive off a relieving Muslim force by the timely discovery of the Holy Lance. The Latin principality of Antioch, under Bohemund I (*q.v.*) and his successors, was administered in virtual independence of the kings of Jerusalem, though these retained their claim to it as a fief. It finally fell to Baybars I, sultan of Egypt and Syria, in 1268, when 17,000 of its inhabitants are said to have been killed and 100,000 taken captive. In 1401 it was further scourged by Timur, so that 31 years later the traveler Bertrandon de la Brocquière found no more than 300 houses occupied in Antioch, and they almost all by Turkmen and Arab herdsmen. (WM. C. B.)

Modern Antioch (Antakya).—In 1516 Antioch was captured by the Turkish sultan Selim I. Under Ottoman rule it lost its importance owing to the competition of Damascus. It was part of the Turkish empire until after World War I, when it was transferred to Syria under French mandate. A Turko-French agreement of July 1938 gave the Turkish army the right to take part in the administration of Hatay *il* (province), and later the town shared in the independence of the *il* which became the Republic of Hatay. On June 23, 1939, this territory voted to join Turkey.

Antioch (1960 pop. 45,848) is the capital of Hatay *il*. The larger part of the town is on the eastern bank of the Orontes and climbs the slopes of Mt. Habib-Necar, which is crowned by considerable remains of the ancient citadel. The newer quarters are on the western bank and a bridge (partly ancient) links the two parts. The town is irregular in plan and consists of narrow, winding streets and a mass of crowded houses, usually stone-built in Roman or old Persian style with a single story enclosing a courtyard with a fountain. It is surrounded by extensive orchards. The archaeological museum contains collections of mosaics, coins and other items. The climate is healthy; winters are rainy and mild, and summers dry and hot, but a steady cool breeze mitigates the heat.

The town stands at the junction of important roads, one eastward to Aleppo and the other north-south from Syria to Adana and the southern Turkish coast. The importance of the town has varied with the economic and political significance of these roads. Today its activities are based mainly on the agricultural produce of the adjacent area, including the intensively cultivated Amik plain. The chief crops are wheat, cotton, grapes, rice, olives, vegetables and fruit; the town possesses soap and olive-oil factories and cotton ginning and other processing industries. Silk, shoes and knives are also manufactured. To the south are the cascades of Daphne (Harbiye), a popular resort.

ANTIOCH, GREEK ORTHODOX PATRIARCHATE OF. The patriarch of Antioch and all the east, who is in communion with the Greek and other Eastern Orthodox Churches, is generally called the Greek Orthodox patriarch. He is regarded as the successor of St. Peter in the see of Antioch and the third in rank of the Orthodox patriarchs, after the ecumenical patriarch (of Constantinople) and the patriarch of Alexandria.

In the 5th, 6th and 7th centuries, after the Council of Chalcedon in 451, the christological conflicts which arose in Syria and in regions east of Syria caused the authority of the patriarch of Antioch to be limited, for practical purposes, to the community of people known as "Romans" or "Melkites" (*i.e.*, emperor's men) because they were in communion with the Byzantine (east Roman) emperor. The literary language of this community was Greek; Syriac was associated with the people who were not in communion with the Greeks. There is, however, much evidence of the use of a Syriac translation of the services of the Greek Church in various

parts of Syria after the separations just mentioned, so that it cannot be said that it was only the Greeks who remained Orthodox and in communion with Constantinople. From the 9th century onward there were parishes where Arabic was the only language generally known, and therefore parts of the church services were translated into Arabic. In modern times the growth of nationalism, the breakup of the Ottoman empire and the disappearance of the Greeks from Asia Minor have caused the Greek Orthodox patriarchate of Antioch to assume the character of an Arab Eastern Orthodox Christian institution.

Since the 14th century the patriarch has resided in Damascus. There are metropolitans under his jurisdiction in Syria (Homs, Hama, Aleppo, Latakia and Suweida), Lebanon (Beirut, Tripoli, Hadeth, Halba, Zahle and Merj'Uyun), Baghdad and New York. This last metropolitan, together with an archbishop in Toledo, O., and a patriarchal delegate in Buenos Aires, take charge of the Arab Eastern Orthodox in the Americas. The principal liturgical language of the patriarchate is now Arabic, but Greek is still used, and English in the United States.

The number of members of the Eastern Orthodox Church under the patriarch's jurisdiction is variously estimated, but there are probably at least 400,000. In Syria they form the largest Christian community. In Lebanon they are the second largest church after the Maronites (*q.v.*). In both countries they are Arab in their conception of their nationality, whereas the Maronites and the "Syrian Orthodox" are inclined to think of themselves as survivals of pre-Arab nations. They call themselves Greek or "Roum" for historical reasons and in order to distinguish themselves from other churches using the word Orthodox in their names, but they are nevertheless an indigenous community, with an indigenous hierarchy, although there are naturally a few parishes of Greek residents. *See* also ORTHODOX EASTERN CHURCH.

See C. Karalevsky, "Antioche," in A. Baudrillart, *Dictionnaire d'histoire et de géographie ecclésiastique,* vol. iii, col. 563–703 (1924). (E. E.)

ANTIOCH, SYRIAN ORTHODOX PATRIARCHATE OF. This patriarchate administers the affairs of a body of Syrian Christians frequently called Jacobites. In the 5th and 6th centuries A.D. a large body of Christians in Syria and beyond its borders repudiated as heretics the patriarchs of Antioch who were supporters of the Council of Chalcedon (451) and set up their own patriarchs of Antioch in opposition to the Chalcedonian patriarchs, whom they called Melkites (emperor's men). Like the Copts, Ethiopians and Armenians, they held the doctrine called "monophysite," that Christ is not "in two natures," but is "one nature out of two natures" (*see* COPTIC CHURCH; MONOPHYSITES). They were called Jacobites because of the important part played by the celebrated Jacob Baradaeus, bishop of Edessa (d. 578), in organizing their community. They were also called the Syriani when their doctrine had been extinguished among Greek-speaking people and was associated with the use of Syriac. The Chalcedonians of Syria were known as Roumi (*see* ANTIOCH, GREEK ORTHODOX PATRIARCHATE OF).

After the Arab conquest of Syria each church in the Arab caliphate and in Muslim states generally was treated as a millet (religious community), being governed by its own laws and law courts under the leadership of its own clergy. The Syriani were recognized as the West Syrian millet (the East Syrian millet being the Assyrians or Nestorians, *q.v.*). Since the 17th century, when a minority of them were united with Rome and became the Syrian Catholics, the rest of the West Syrians have been known as Syrian Orthodox. Their liturgical language is the literary Syriac of Edessa, which they preserve as a living tongue; it is closely akin to the Aramaic spoken by Jesus Christ and his apostles.

The Syrian Orthodox patriarch of Antioch has very seldom lived in Antioch itself; his usual residence was the monastery of Deir al Zapharan near Mardin, near Diyarbakir in eastern Asia Minor. The Syrian Orthodox had villages in the mountains in that region and also near Mosul and in the districts of Aleppo and Homs. During World War I most of them left Turkey and their patriarch moved to Homs (1921) and then to Damascus (1959). They now live in Lebanon, Iraq, Turkey and Syria and in smaller numbers in Jordan, Egypt and the United States. Since the 17th century those Syrian Christians on the Malabar coast of southern India who have not been united with Rome have been, for the most part, under the ecclesiastical authority of the Syrian Orthodox patriarch of Antioch (*see* MALABAR CHRISTIANS).

See W. A. Wigram, *The Separation of the Monophysites* (1960). (E. E.)

ANTIOCH COLLEGE, in Yellow Springs, O., founded in 1852 as an interracial, coeducational college, was also a pioneer in the co-operative work-study plan. *See* YELLOW SPRINGS.

ANTIOCH IN PISIDIA, an ancient city, the remains of which lie close to the modern Yalvac, in the *il* of Isparta in Turkey. It was situated on the slopes of the Sultan Daglari range on the more southerly of the two great highways which led from the Maeander valley to the Cilician Gates. Founded by Seleucus I on the territory of a Phrygian sanctuary, it became a Greek-speaking centre in a Phrygian area, with a mixed population, including many Jews. The Romans made it a free city in 189 B.C. Before 11 B.C., however, the emperor Augustus made it a colony, with the title Caesarea, and confiscated the temple lands as imperial estates. It became the centre of civil and military administration in southern Galatia, the romanization of which was progressing rapidly when, in the time of the emperor Claudius, St. Paul made it one of the centres of his mission in that province. In 1097 the crusaders found rest and shelter within its walls. The ruins include those of fortifications, of a theatre, a temple, a church, an aqueduct and also of a rock cutting which may have held the temple of Men Ascaenus, the local Phrygian deity. (WM. C. B.)

ANTIOCHUS, the name of 13 kings and of several other princes of the Seleucid dynasty (*q.v.*), and also of four kings of Commagene (69 B.C.–A.D. 72), where the dynasty was related to the Seleucids.

The more important Seleucids of that name are described below.

ANTIOCHUS I SOTER (324–262 or 261 B.C.), the son of Seleucus I Nicator and the Iranian princess Apama, from *c.* 293 ruled the eastern regions of his father's kingdom from Seleucia on the Tigris, having the royal title and an equal share of power. At his accession to the rest of his father's kingdom (280) there was a serious revolt in Syria and movements toward local independence in Asia Minor; consequently he did not attempt the occupation of Thrace and Macedonia envisaged by his father. At first he fought with Antigonus II Gonatas, but came to terms with him in 279. About 275 he won a victory over the Celts in Asia Minor and took the name Soter ("saviour"). The First Syrian War with Egypt (276–272) caused the loss of much Seleucid territory along the southern and western coasts of Asia Minor and in the Aegean, and a war with Eumenes I of Pergamum ended in the defeat of Antiochus near Sardis (262). He died soon afterward.

Antiochus I spent much time in his eastern provinces, where his half-Iranian origin was an advantage. He founded new Greek settlements, chiefly in Iran and Asia Minor. He was an able successor to his father, whose work he consolidated in the face of great difficulties.

ANTIOCHUS II THEOS (*c.* 287–*c.* 247 B.C.) was the second son of Antiochus I, whom he succeeded *c.* 261. He fought a war with Egypt (*c.* 260–255), the Second Syrian War, of which few details are preserved; probably he recovered much ground lost by his father in Asia Minor. He married a cousin, Laodice, but repudiated her *c.* 252 and married Berenice (*q.v.*), daughter of the Egyptian king Ptolemy II Philadelphus. It is not clear why he should have fallen under Ptolemy's influence after opposing him vigorously earlier in his reign.

The designation of Antiochus II as Theos ("the God") in public documents indicates that the Seleucid kingdom had by this time adopted the cult of the living ruler.

ANTIOCHUS HIERAX or "the Hawk" (*c.* 263–226 B.C.) was a son of Antiochus II and the younger brother of Seleucus II Callinicus. Thanks to his mother Laodice's influence and his brother's difficulties in the Third Syrian War (246–241) against Ptolemy III Euergetes I, he became independent ruler of the Seleucid domains in Asia Minor north of Mt. Taurus, a position he maintained by means of alliances with Galatia, Bithynia and Pontus until his

exile (227) and death in Thrace.

Antiochus III the Great (*c.* 242–187 B.C.) was the younger son of Seleucus II and the brother of Seleucus III Soter whom he succeeded as king in 223. Still quite young, he had to rely at first upon the leading men in the state; his cousin Achaeus was entrusted with Asia Minor and the conduct of the war against Attalus I of Pergamum; control over the eastern provinces was given to Molon and his brother Alexander, governors of Media and Persis respectively; at the centre of the kingdom the guidance of the chief minister Hermias was all-important.

In 221 Molon set himself up as independent ruler of the central regions of the empire, after the manner of the Bactrian and Parthian kings. Antiochus on the advice of Hermias had begun a campaign against the Ptolemaic forces in southern Syria, but Molon's secession was so grave a threat to the empire that he abandoned the campaign in Syria, marched eastward and defeated Molon in a battle beyond the Tigris (220). Shortly afterward Antiochus killed Hermias and thus came to exercise full power.

In the Fourth Syrian War with Egypt Antiochus won victories in Palestine and Phoenicia in the years 219 and 218, and in 217 he marched to the frontier of Egypt itself and engaged Ptolemy IV Philopator in a major battle at Raphia (Rafa), with 68,000 men against 55,000. He himself was victorious against the enemy's left, but in the centre his phalanx was defeated by the newly formed Egyptian phalanx. Unable to retrieve the situation, Antiochus fled north to Antioch on the Orontes. Coele-Syria (Lebanon), Palestine and Phoenicia reverted to Ptolemy's control, but the latter did not exploit his advantage. Antiochus was granted a peace and left a free hand against Achaeus, who had assumed the royal title in Asia Minor (220) and whom he eventually captured and executed (214).

Antiochus now turned to the formidable task of rebuilding his empire in the east. In 212 he brought Armenia back to its tributary status; the next two years he spent in preparing a great expedition against the Parthian and Bactrian kingdoms, which had absorbed large tracts of Seleucid territory since their formation in the middle of the century (*see* Bactria; Parthia). In the following years (209–205) Antiochus defeated the Parthian and Bactrian kings and recovered the eastern provinces. This immense achievement justified the king's assumption, on his return to Babylon, of the ancient Achaemenid title of "great king." Henceforth he is known to the world as Antiochus the Great.

About 203 Antiochus formed a secret pact with Philip V of Macedonia for the partition of the Ptolemaic empire outside Egypt. The events of the next five years are obscure, but it appears that Antiochus overran Coele-Syria, Palestine and Phoenicia and confirmed his conquest of these territories later by a decisive victory over the Ptolemaic general Scopas at Panium near the source of the Jordan (*c.* 200). He did not, however, attack Egypt itself, and eventually he made peace with the young Ptolemy V Epiphanes, giving him his daughter Cleopatra in marriage (*c.* 195).

After the victory of Panium Antiochus tried to strengthen his position in western Asia Minor, apparently by exploiting the weaknesses of both Egypt and Macedonia so as to make easy conquests for himself. He was resisted by Pergamum and Rhodes, and these states persuaded Rome to send him messages of warning. Undeterred, he pressed on, winning several cities in Aeolis and Ionia. In 196 he crossed into Europe and made conquests in Thrace, where he claimed sovereignty over territory won by Seleucus I on the death of Lysimachus (281). Roman orders to withdraw from these and the earlier conquests he rejected.

About 195 Hannibal (*q.v.*) took refuge at the Seleucid court, a happening which increased Roman fears and suspicion. Antiochus, exasperated both by the encouragement given to his enemies by Roman ambassadors and by the Roman senate's refusal to grant him a treaty of friendship under which his territorial rights would be secured, decided to intervene in Greece, where he could embarrass Rome by posing as a liberator. The Aetolians offered to join him, and he landed in Greece in the autumn of 192.

He accomplished little: his expedition had been badly prepared, his army was too small, Aetolian help was inadequate and Philip and the Achaean league joined hands with Rome to frustrate him. Routed by the Romans at Thermopylae (191), he withdrew to Asia. At sea the Seleucid fleet was beaten in several engagements by the Roman, Pergamene and Rhodian forces; the Roman army crossed unopposed into Asia. The final battle was fought at Magnesia ad Sipylum west of Sardis (winter 190–189). Antiochus' army (70,000) heavily outnumbered that of the Romans and their allies (30,000), and Antiochus fought bravely but was in the end completely defeated. By the treaty of Apamea (188) he was obliged to renounce all Seleucid claims in Europe and north of Mt. Taurus, to pay an indemnity of 15,000 talents over a period of several years, to hand over 20 selected hostages and to surrender the fleet and the elephants. In the next year Antiochus was killed in Elymaïs (Elam) while engaged in plundering a temple.

Antiochus III combined personal bravery with prudent judgment and a strict devotion to his duties as a king. His achievements in the east and against Egypt greatly strengthened his kingdom, and in spite of his failure against Rome (caused by a pardonable miscalculation of the chances) he may be ranked as the most successful of the Seleucid kings after Seleucus I.

Antiochus IV Epiphanes (*c.* 215–163 B.C.), ruler of the Seleucid kingdom from 175, was the third son of Antiochus III. After the battle of Magnesia he was one of the hostages sent to Rome, where he received kind treatment and learned to admire Roman institutions and policies. After the assassination of his brother Seleucus IV Philopator he seized the throne from the usurper Heliodorus (175), being aided by Eumenes II of Pergamum with whom he subsequently concluded an alliance.

In 170 Egypt attempted to reconquer Palestine. Antiochus easily defeated this attempt and in his turn invaded and occupied Egypt, where he set up a protectorate over Ptolemy VI Philometor. When he withdrew, however, his political system in Egypt collapsed, and he returned to besiege Alexandria. Rome then intervened, ordering Antiochus to evacuate both Egypt and Cyprus, which he had already seized. He complied after undergoing public humiliation in a scene with the Roman envoy Gaius Popilius Laenas at Alexandria (168), for he realized that to challenge Rome would be a hopeless venture.

Within his empire Antiochus encouraged city life and the diffusion of Greek culture—a policy that he carried out with especial fervour (his passionate attachment to Hellenism had first been revealed before his accession, when he was living in Athens). Enthusiastic for republican forms, he ignored his kingly rank and mingled familiarly with the citizens of Antioch. His general policy, however, was to unify and strengthen his empire by means of a common culture. Noteworthy marks of his religious policy were his assumption of the title Epiphanes ("god manifest") and his identification with Zeus, perhaps in deliberate imitation of Alexander III the Great.

Antiochus IV's contact with the Jews is known chiefly from Jewish writers hostile to him, and the documents that they cite are perhaps not authentic (in particular a supposed letter of his to the Jews). It seems certain, however, that he placed a permanent garrison in Jerusalem in 167 and set up the worship of Olympian Zeus in the Temple. To him these actions were merely the local application of his general policy; to the stricter kind of Jew they were an intolerable provocation that could be answered only by armed defiance. As a result the Seleucid government became involved in a long and difficult war with a large part of the Jewish people. (*See* Jews.)

Under Antiochus IV the Seleucid empire recovered much of the strength it had lost through the Roman victory over Antiochus III; probably many new Greek settlers were brought in, especially to Cilicia and the eastern provinces. The great review of the army at Daphne near Antioch in 166 was intended as a political demonstration to impress the Greek world, and it may also have been a triumph to celebrate the success of Eucratides in overthrowing Demetrius, the king of Bactria, if it is true that Eucratides had acted as an agent or ally of Antiochus.

The final years of the reign saw the start of an attempt to move against Parthia, perhaps with the collaboration of Eucratides. But after traversing the central districts of the empire, and be-

fore he could engage the enemy, Antiochus died of consumption at Gabae (Isfahan) in Persis in 163.

Some aspects of Antiochus IV's behaviour seemed eccentric to his contemporaries, but in the main he was well regarded and his abilities were considerable.

ANTIOCHUS VII SIDETES (*c.* 159–129 B.C.) was the second son of Demetrius I Soter and succeeded his brother Demetrius II Nicator as ruler of the Seleucid empire in 139. After subduing Judaea (134) he drove the Parthians out of Babylonia and recovered much of the territory they had overrun (130). The next year he was defeated and killed by the Parthians in Media, and the last hope of saving the eastern provinces of the empire died with him. He was the last Seleucid king of importance. The name Sidetes refers to his having been brought up in the Greek city of Side in Pamphylia.

See SELEUCID DYNASTY for bibliography. (R. H. SI.)

ANTIOCHUS OF ASCALON (? d. 68 B.C.), Greek philosopher, succeeded Philo of Larissa as head of the Academy (*see* ACADEMY, GREEK). He redirected the main stream of Platonism from the skepticism of Arcesilaus and Carneades to positive philosophy. His view that Platonism, Peripateticism and Stoicism differed more in terminology than in fact influenced many who did not entirely accept it, including Cicero, who heard his lectures in 79–78 and leaned heavily on his writings (now entirely lost) for the composition of his *Academica,* his *De Finibus* and, probably, others of his philosophical works. Antiochus' own philosophy was eclectic in the sense that he tried to construct a consistent body of doctrine from the material offered by the three schools, but its form was largely determined by Stoicism. (F. H. SH.)

ANTIOPE, the name of two figures in Greek legend.

1. Antiope, the mother by Zeus of Amphion and Zethus. Her beauty attracted Zeus, who, assuming the form of a satyr, took her by force. Pregnant, she escaped the threats of her father by running away and marrying Epopeus, king of Sicyon. Thereupon her father killed himself, first bidding his brother Lycus punish her. Lycus killed Epopeus, brought Antiope back, and imprisoned and tormented her. (In another account Antiope had been married to Lycus, but was rejected by him after an affair with Epopeus. Lycus' second wife, Dirce, daughter of Helios, captured and tortured Antiope out of jealousy.) On the way back from Sicyon, or after escaping from prison, Antiope bore twins, Amphion and Zethus, who were brought up by herdsmen. Long afterward, she escaped and joined her sons; they recognized her, killed Lycus, and bound Dirce to the horns of a wild bull, in which posture she died. After Dirce's death her body was cast into a spring near Thebes, later called by her name. Because of her murder, Dionysus, to whose worship Dirce had been devoted, visited Antiope with madness, which caused her to wander restlessly all over Greece until she was cured and married by Phocus of Tithorea, on Mt. Parnassus, where both were buried in one grave.

2. Antiope, daughter of Ares, sister of Hippolyte, queen of the Amazons. Theseus (*q.v.*) stole her for his wife. (T. V. B.)

ANTIOQUIA, a mountainous interior department in the northernmost Andes of Colombia, bounded by Bolívar and Córdoba on the north, the Magdalena river (*q.v.*) on the east and Chocó and Caldas on the west and south. A narrow corridor reaches to the Caribbean sea at Turbo. Area 24,324 sq.mi.; pop. (1961 est.) 1,931,690. Its rugged mountain mass is bisected by the deep gorge of the Cauca river (*q.v.*). Most of the eastern half, between the Cauca and the Magdalena, is an ancient granitic batholith (average elevation 8,000 ft.), the northernmost extension of the Central Cordillera. Unlike the country to the south, Antioquia has been little affected by recent volcanic activity, and its upland soils are for the most part deeply weathered and rather infertile. The Antioquia highland is diagonally pierced by the deep canyon of the Porce river, a Cauca tributary, which widens out in its upper reaches into the lovely, mile-high valley where the capital city of Medellín (*q.v.*) is situated. The surrounding uplands are laced with gold-bearing quartz and calcite veins.

The colonial economy of Antioquia was based on mining, but as the mines gave out agriculture became increasingly important. Coffee, introduced in the 1880s, is the principal export crop. The manufacturing industries of the valley of Medellín, especially textiles, have made Antioquia the leading industrial department of Colombia despite its relative geographical isolation.

After 1800 Antioqueño colonists began moving onto the empty volcanic-ash slopes to the south in a wave of colonization that has continued to the present day. More than one-half of the people who call themselves Antioqueños live outside Antioquia. Long isolation has made the Antioqueños noteworthy for their cultural conservatism, reflected in dress, diet and speech. Their aggressive individualism is legendary in Colombia. The rural society is composed largely of small holders. (Js. J. P.)

ANTIOXIDANTS, chemical compounds sometimes added to certain foods, natural and synthetic rubbers, gasolines and other substances to retard autoxidation, the process in which these substances combine with oxygen in the air at room temperature. Retarding autoxidation delays the appearance of such undesirable qualities as rancidity in foods, loss of elasticity in rubbers and formation of gum in gasolines. The activity of most antioxidants is due to their ability to donate hydrogen atoms. They are effective at very low concentrations, sometimes as low as 0.001%. The efficient antioxidants are organic compounds, such as aromatic amines, phenols and aminophenols.

This article does not deal with oxidation at high temperatures (*see* COMBUSTION), biological oxidation (*see* RESPIRATION) or oxidation of metals (*see* CORROSION AND OXIDATION OF METALS).

The Four Stages of Autoxidation.—The general course of autoxidation usually can be divided into four successive stages in regard to the rate of reaction with oxygen: (1) the initial period of negligible rate; (2) the period of accelerating rate; (3) the period of nearly constant rate; and (4) the final period of declining rate. The duration of the first stage plus the slow portion of the second is termed the induction period and, in most cases, indicates the useful lifetime of the autoxidizable substances.

These facts are consistent with a mechanism of oxidation based on the theory of chain reactions, the modern form of which was developed through the works of many investigators beginning with Walther Nernst (1911), Max Bodenstein (1913) and J. A. Christiansen and H. A. Kramers (1923).

A chain reaction consists of a series of successive reactions occurring in repetitive cycles, in each of which intermediate products called chain carriers are regenerated. Such a reaction will continue as long as the chain carriers persist. In autoxidation the chain carriers are free radicals. They are electrically neutral molecular fragments resulting from the rupture of covalent bonds and always containing one or more unpaired electrons. The covalent bond is the ordinary chemical bond in organic compounds and is formed by the union of a pair of electrons. When this bond is broken the two fragments divide the pair of electrons, thus giving rise to two free radicals, each with an unpaired electron. Although different kinds of free radicals vary greatly in reactivity they all combine, two by two, to form stable molecules containing a new covalent bond. The carriers that propagate chain reactions, however, are always very reactive free radicals. In most cases the bond that breaks is one of the weakest carbon-hydrogen bonds in the autoxidizable molecule. The different reactions involved in autoxidation can be represented as follows:

Let R:H be the autoxidizable compound, the H be the hydrogen atom of the weak C:H bond, the : be the electron pair of the covalent bond, and . be the unpaired electron of an atom or a free radical.

1. Chain initiation

   $R{:}H \rightarrow R. +$ (H. removed by the initiating agent)

2. Chain propagation

   a. $R. + O_2 \rightarrow R{:}O{:}O.$ (hydroperoxide free radical)

   b. $R{:}O{:}O. + R{:}H \rightarrow R. + R{:}O{:}O{:}H$ (hydroperoxide)

3. Chain termination

   Elimination of R. and R:O:O. in different ways.

The chain can be initiated by thermally excited molecules, free radicals, metal catalysts or light, but in any case this requires a greater input of energy than any of the other steps. The number of times the propagation reactions are repeated determines the chain length; a short chain consists of a few cycles while a

long one goes into the thousands. Hence, the destruction of the original R. or R:O:O. right after its formation will prevent the creation of that number of chain-propagating free radicals which would have been formed if the chain reactions had been permitted to proceed.

Most hydroperoxides are not stable enough to accumulate to any great extent in the autoxidizing system, but are converted into oxygen-containing products. In the course of this conversion free radicals are formed which initiate additional chain reactions to speed up the rate of oxidation. This process is called degenerative chain branching because it is dependent upon the decomposition of the hydroperoxides and causes the chains to branch or multiply.

Antioxidants Inhibit Deterioration.—Antioxidants, by reacting with chain carriers from all sources, prolong the induction period and thereby retard the oxidative deterioration of the products. They, in turn, become free radicals of low energy content that change into stable compounds. Antioxidants can react with a free radical R. (or R:O:O.) in two different ways.

1. R. + antioxidant → R:H + stable products
2. R. + antioxidant → stable products containing R:

In the first case the antioxidant must contain an easily available hydrogen atom, and in the second it must have a double bond to which R. can be added. It is also conceivable that the antioxidant is first converted by partial oxidation into relatively stable free radicals that capture the chain carriers. Within practical limits the increase in induction period for a given system tends to be directly proportional to the concentration of a particular antioxidant. The response of autoxidizable substances to antioxidants varies greatly, and the efficiencies of different antioxidants in a specific product cover a wide range. Examples of commercial antioxidants are given below.

Antioxidants that are destroyed while performing their function are referred to as sacrificial antioxidants. They can also be destroyed in the autoxidizable system: (1) by reacting with hydroperoxides, but this can happen to a significant extent only if hydroperoxides had been formed during active autoxidation before the addition of the antioxidants; and (2) by reacting directly with molecular oxygen, in which case they are wasted. Antioxidants, therefore, should be added to the products to be protected as soon as possible after recovery or production, and they should not react too easily with oxygen.

Autoxidation is greatly influenced by the presence of acidic and basic compounds, heavy metal catalysts, divalent sulfur compounds and by light. The choice of antioxidant will depend to some extent upon these factors, but it is better to counter the catalysts with anticatalysts that render them ineffective. Metal catalysts can be deactivated with compounds that convert them into inert metal complexes, such as N,N′-disalicylidene-1,2-diaminopropane for copper salts. Acids and bases can be neutralized. Most of the common antioxidants are not suited for use in products exposed to direct sunlight because they tend to initiate photo-reactions, unless opacity minimizes this danger.

Finally, before an antioxidant can be considered satisfactory for practical use it must meet certain subsidiary requirements depending upon the particular use: (1) it must be sufficiently soluble in the product; (2) its volatility must be relatively low; (3) it must not be extracted by water; (4) it must not be coloured; (5) it must be odourless and tasteless; (6) it must not be toxic or irritating to the skin; and (7) it must not cost too much.

Many products, such as rubber latex, wheat germ oil, thermally cracked gasoline and lubricating oil, contain natural antioxidants, but they are frequently lost during refining or are not effective enough when the products are put to human use.

Acrolein.—Although some efforts were made to control autoxidation by chemical means prior to the work of Charles Moureu and Charles Dufraisse on acrolein beginning in 1917, these investigators must be given the credit for having started the modern developments in commercial antioxidants. Thereafter antioxidants helped to improve many critically important materials, including rubber, gasoline, lubricants and vinyl compounds and foods.

On aging, rubber darkens and loses its elasticity and tensile strength. N-Phenyl-beta-napthylamine, 4,4′-dimethoxydiphenylamine, N,N′-diphenyl-para-phenylenediamine and 2,2′-methlene-bis-(4-methyl-6-tertiary-butylphenol) are good antioxidants, the last being considered a light stable one. They are used at about 0.5% to 3% by weight on the rubber.

The autoxidation of cracked gasoline results in the formation of gums that foul the engine. N-Butyl-para-aminophenol and N,N′-di-(secondary butyl)-para-phenylenediamine are effective antioxidants at 0.001% to 0.01% by weight. Phenols with alkyl substituents in the ring are also used.

Nordihydroguaiaretic acid, ring-alkylated para-hydroxyanisole, propyl gallate and tocopherol are added to fats and oils to retard the development of rancidity. The dosage ranges from 0.005% to 0.1% by weight. They are frequently used in combination with lecithin, citric acid or ascorbic acid. In this case efficiency must be made secondary to edibility because compounds put into foods for human consumption must meet stringent government specifications.

Although antioxidants are not necessarily inhibitors of polymerization, they are used to prevent the formation of peroxides in vinyl monomers because the peroxides are sometimes dangerous and usually cause polymerization. Hydroquinone, catechol, alpha-naphthol and phenothiazine are examples of such antioxidants.

Many aldehydes autoxidize rapidly to give high yields of carboxylic acids. Benzaldehyde, for example, goes to benzoic acid. Most of the antioxidants mentioned above protect aldehydes.

The mechanism of antioxidant action has been studied by means of the deuterium isotope effect, but by the early 1960s the mechanism had not been fully elucidated.

ANTIPAROS (mod. Gr., ANDIPAROS), a Greek island, one of the Cyclades, lies in the Aegean sea, in the modern eparchy of Naxos, separated by a narrow strait from the west coast of Paros. It is 7 mi. long by 3.4 mi. broad. The two islands lie about half way between the Greek and Turkish coasts. The population (1951) of 680, mostly in Kastro on the north coast, is employed in agriculture and fishing. Its ancient name was Oliaros. It shared the Early Bronze Age culture of the Cyclades, but little is heard of it in the classical period, when its fortunes were bound with those of Paros. In later times piracy was common. The only remarkable feature in the island is a stalactite cavern on the south coast, reached by a dangerous descent. The grotto is about 150 by 100 ft. and 50 ft. high, and was visited in antiquity. The island is well cultivated and fertile. (J. Bo.)

ANTIPATER (*c.* 397–319 B.C.), Macedonian general and regent of Macedonia from 334 to 323 B.C. and of the Macedonian empire from 321 to 319. He was entrusted with high responsibilities by Philip II of Macedonia, such as the negotiation of the peace of Philocrates with Athens in 346. One of the leading men in the state at Philip's death in 336, he helped to secure the succession for Alexander III the Great (*q.v.*), who, on his departure for Asia (334), appointed Antipater regent in Macedonia with the title of general in Europe. His main tasks were to hold the northern frontiers against barbarian tribes and to keep order among the Greek states. He ruled Greece by co-operating with the League of Corinth, but was unpopular because he restored tyrants expelled from their cities and favoured oligarchic governments.

In 331 at Megalopolis he defeated the Spartan king Agis III.

The settlement of the satrapies of the Macedonian empire by Perdiccas (*q.v.*) at Babylon in 323, immediately after Alexander's death, left Antipater as general in control of Macedonia and Greece, though his status in relation to that of Perdiccas was not clearly defined. From 323 to 322 he had to fight a difficult campaign against the Athenians, Aetolians and Thessalians, the so-called Lamian War, which he eventually won at Crannon after receiving reinforcements from Asia. He took the side of the Macedonian generals Antigonus, Seleucus (*qq.v.*) and Ptolemy (*see* PTOLEMIES) who were opposed to the claims of Perdiccas, and in the settlement at Triparadisus in Syria (321) he became regent of the Macedonian empire for the two kings Philip III Arrhidaeus and the infant Alexander IV, until his death in 319 which was the signal for the regional governors to throw off allegiance to central authority. (R. H. SI.)

ANTIPHANES (fl. early 4th century B.C.), Greek poet, was the most important writer of Middle Attic Comedy with the exception of Alexis. He was apparently a foreigner who settled in Athens and may have been producing by 387 B.C. About 120 of the many comedies attributed to him are known from their titles and considerable fragments are preserved in Athenaeus' *Deipnosophistai*. In all over 300 fragments survive. For the fragments *see* T. Kock, *Comicorum Atticorum fragmenta*, vol. ii (1884).

See T. B. L. Webster, *Studies in Later Greek Comedy* (1953).

ANTIPHON OF RHAMNUS in Attica (*c.* 480–411 B.C.) was one of the earliest professional speech-writers in Greece. An extreme oligarch, he played a leading part in overthrowing the democratic system at Athens in 411 B.C. When later in the same year the oligarchic government was deposed he was accused of treason, condemned and executed. The speech he made in his own defense, of which papyrus fragments have survived, was highly praised by Thucydides. There is little reliable information about his earlier life. He wrote speeches for public and private litigants and probably taught rhetoric. According to Thucydides he was reluctant to speak in public himself as his reputation for rhetorical skill made the people suspect him.

Three speeches written for actual lawsuits are extant. All deal with cases of homicide. In *Kategoria Pharmakeias Kata tes Metruias* ("Charge of Poisoning Against the Stepmother") a man accuses his stepmother of murdering his father by inducing a slavewoman to poison his wine. Some scholars have held that Antiphon was not the author or that he wrote it merely as an illustrative model for his pupils, but it is now generally believed to be a real speech by Antiphon. *Peri tou Heroidou Phonou* ("The Murder of Herodes") is the defense of a man accused of murdering his companion when they had put ashore during a voyage. *Peri tou Choreutou* ("On the Choreutes") defends a *choregus*, or chorus trainer, alleged to have been responsible for the death of a chorister who had been given a drug to improve his voice.

The *Tetralogies* ascribed to Antiphon by antiquity concern three imaginary cases of homicide. In each case there are two speeches for the prosecution and two for the defense after the usual Athenian procedure. They were evidently written to show students of rhetoric how real cases should be handled. Although they deal with processes which might have arisen in everyday life at Athens, they do not aim to be realistic imitations of genuine speeches. They are rather outline-speeches inculcating general principles, and little is said about the details of each particular case. No one in ancient times seems to have doubted their authenticity, but this has aroused considerable controversy among modern scholars. Objections to Antiphon's authorship are based both on the matter and the language. The speakers do not recognize the distinction between different types of homicide which was well established in Athenian law by Antiphon's time, and there are striking divergences in grammar and vocabulary from his three real speeches. The controversy has not been resolved, but the difficulty of comparing fictitious speeches with those written for actual processes has probably inclined scholars to accept Antiphon's authorship. Fragments of other speeches attributed to Antiphon survive; these come from speeches written for public as well as private suits. He was also said to have written a handbook of rhetoric, and a collection of prefaces and perorations.

Antiphon is the author of the earliest extant legal speeches; it is even stated by some ancient authorities that he was the first to commit legal speeches to writing. Oratory had for long been a highly developed art at Athens, but in Antiphon's day two new factors combined to shape its growth. The first was the theoretical study of forensic speaking, which began in Sicily after the fall of the tyrants. The second was the increased importance of prose literature generally and the desire to give it a beauty of form analogous to that of verse. Both these factors had their effect on Antiphon's work. The influence of Sicilian rhetoric is seen in the formal structure of his speeches and the character of his arguments. The real speeches are divided into five sections: (1) a preface; (2) an introduction describing the circumstances of the case; (3) a narrative of facts; (4) proofs and arguments; (5) a peroration. The *Tetralogies* omit the introduction and narrative of facts. In all the speeches the arguments depend more on abstract probabilities than on close reasoning from factual evidence. Rhetorical chicanery is not infrequent.

Antiphon's prose reflects stylistic experiments which were being made in the last part of the 5th century B.C. By comparison with Gorgias he is economical in the use of pretentious embellishments, but even in the speeches written for delivery in court carefully balanced clauses and forced antitheses show a self-conscious artistry. In the *Tetralogies* this is still more evident. After Antiphon practical oratory tended to avoid such ornament. A jury might appreciate it, but would suspect that it concealed a weak case. Antiphon lacked Lysias' talent for adapting his style and language to the character of the client by whom the speech was to be delivered. The general tone is one of dignity, even of grandeur. He avoids colloquial expressions and does not descend to the personal invective which was common among later orators, notably Demosthenes.

Editions of Antiphon include F. Blass and T. Thalheim, Teubner series (1914); L. Gernet, with French translation, Budé series (1923); K. J. Maidment in *Minor Attic Orators*, vol. i, with English translation, Loeb series (1954).

Zuntz, "Once Again the Antiphontean Tetralogies," *Museum Helveticum*, vol. vi (1949). (H. L. H.-W.)

ANTIPHON, a chant sung by two alternating choirs. The earliest reference to this method of singing occurs in *De vita contemplativa* by the Jewish chronicler Philo, writing in the first half of the 1st century A.D., where two choirs of men and women in a religious sect near Alexandria sing in a manner compared by Philo to that mentioned in connection with Moses' "Hymn of Victory" (Ex. xv, 20–21). The Syrian Church developed the practice of antiphonal singing and the liturgical chants sung in that manner were called antiphons. Their place in the church service is in the hours of the office (*see* HOURS, CANONICAL) before and after a psalm or canticle. There are in the repertory of the Roman Catholic Church several thousand antiphons, which can be reduced to a small number of melodic types of a simple structure. *See* PLAINSONG; ANTIPHONARY. (E. J. WZ.)

ANTIPHONARY, a term first used *c.* A.D. 760 by Pope Paul I in a letter sent with some liturgical books to the Frankish king Pepin III. The term was then used to mean the repertory of chants for the choir: the soloists sang from the cantatorium. Later, it came to mean the collection of melodies used for the office, while those for the mass were collected in the gradual. The first compilation of an antiphonary is attributed to Pope Gregory the Great, in *c.* 600. The most important work in compiling a standard antiphonary, however, was done in 831–832 by Amalarius of Metz (*c.* 780–850), a pupil of Alcuin, who explained his task in a famous treatise, *Liber de ordine antiphonarii*. In present liturgical practice the term antiphonary is used for the collection of melodies sung during hours of the office (*see* HOURS, CANONICAL). *See* also PLAINSONG.

ANTIPHON SOPHISTA, an Athenian sophist of the 5th century B.C., usually regarded as distinct from his contemporary Antiphon the orator, though possibly identical with him. He wrote treatises *On Truth, On Concord, The Statesman* and *On the Interpretation of Dreams*. He was not regarded as a thinker of importance until the publication in 1915 and 1922 of fragments of his *On Truth* found at Oxyrhynchus. These compelled a revision of opinion, but no agreement as to his doctrines was reached.

On one view, his appeal to nature as against convention in morals and in politics was almost wholly nihilistic in character and destructive of the state. On another and probably better view, he believed that nature found full expression only in concord and harmony. He also discussed problems in ontology and attempted to square the circle by a method of inscribed polygons.

For fragments and testimonia *see* H. Diels and W. Kranz, *Fragmente der Vorsokratiker*, vol. ii, 7th ed. (1954). *See* also E. Bignone, *Studi sul pensiero antico*, ch. 1–3 (1938); and M. Untersteiner, *The Sophists*, Eng. trans. (1954). (G. B. Kd.)

ANTIPOPE, one who opposes the legitimately elected bishop of Rome, endeavours to secure the papal throne and, in an extreme instance, succeeds materially in the attempt. This abstract definition is necessarily broad and does not reckon with the complexity of individual cases. The elections of several antipopes are greatly obscured by incomplete or biased records. Indeed, even their contemporaries at times could not decide who was the true pope. One cannot claim, therefore, to formulate a definitively accurate list of antipopes. This article emphasizes the type of historical situation that occasioned the rise of antipopes.

Doctrinal Disagreement.—During the reign of Pope Zephyrinus (*c.* 199–217), the Roman priest Hippolytus vigorously opposed the spread of Monarchianism (*q.v.*), a Trinitarian heresy brought to Rome by Sabellius, which identified the Father and the Son. Hippolytus considered Pope Zephyrinus and his deacon Calixtus culpable for being unwilling to enter the theological debate. When, at the death of Zephyrinus, Calixtus became pope, Hippolytus tried to supplant him. This first antipope was later reconciled to Pope Pontianus during the persecution of Maximinus and died a martyr's death (235).

Deportation of the Pope.—The Arian emperor Constantius II, having exiled Pope Liberius for his orthodoxy (357), imposed the archdeacon Felix on the Roman clergy. He became Felix II. Later Liberius was allowed to return to Rome, the emperor contemplating some form of coexistence. The faithful, however, found the compromise intolerable, and Felix had to leave the city. Having later returned to threaten Liberius' position, he was once more rejected. Felix lived in retirement until his death (365).

Double Election Arbitrated by the Secular Authority.—In 418 the archdeacon Eulalius was elected by a faction partial to him. In protest the rest of the clergy chose the priest Boniface. Eulalius enjoyed the support of the imperial prefect and the Byzantine court. At this juncture the empress began to take an interest in Boniface's cause and asked that the case be reopened. Until a council could be held to decide the issue, the emperor ordered both claimants to leave Rome. Eulalius imprudently returned to perform the Holy Week services at the Lateran, and for this "revolt" official recognition was given to Boniface instead.

Double Election and Subsequent Recourse to a Third Candidate.—On the death of John V (686) no agreement could be reached about his successor. The army favoured the priest Theodore; the clergy, the archpriest Peter. Various attempts at arbitration brought no solution. Finally the clergy set aside Peter to elect Conon, who was also accepted by the army. His reign was short, however, and at his death division reasserted itself. This time Paschal and, once again, Theodore, were rivals for the papal throne. Both were unwilling to renounce their claims. Finally a part of the community more inclined to moderation put forward Sergius and, in the end, obtained the papacy for him.

Political Instability at Rome.—The years 936–973 were marred by continued turbulence as the Theophylact family nominated and deposed popes at will. In 955 the temporal ruler of Rome, Octavian, a boy still in his teens, was elected pope. He became John XII, whose life and court were to be a scandal to Christendom. To consolidate his position John XII appealed for aid to the German emperor, Otto I, giving him in return certain prerogatives in future papal elections. When John later joined an armed conspiracy against Otto, the emperor with his armies descended upon Rome and there presided over a council that gladly deposed the pope and chose in his place Leo VIII (963). When Otto left, John and his partisans returned to expel Leo. At John's death the Romans ignored the emperor's candidate and elected Benedict V. Otto again came to Rome, there to reinstate Leo. Unfortunately peace did not come to Rome and the papacy, even with the eventual triumph of Otto's family.

Change in the Manner of Choosing the Pope.—In 1059 Nicholas II promulgated a decree fixing a new procedure for papal elections. This juridical *coup d'état* deprived the German emperors of the leading role they had played in previous elections. The legates sent by Nicholas to the German court with the decree were refused a hearing; and Nicholas himself was condemned by a council of German bishops and his acts declared null. On his death (1061) the cardinal bishops elected Alexander II in accord with the decree of 1059. Alexander was unacceptable to the German bishops, who resented the limitation put upon their sovereign's power, and to the Roman nobility, likewise deprived of a role in the election. At this point Honorius II was put forward as the candidate of the German court and enjoyed its armed support. When, for a number of reasons, circumstances began to favour Alexander, this patronage was withdrawn. In 1063 St. Peter Damian was instrumental in persuading a diet of German bishops at Augsburg to give its allegiance to Alexander. Soon thereafter, at a council presided over by the imperial legate, the Germans gave Alexander their undivided loyalty. *See* also Papacy.

Tentative List of Antipopes

Hippolytus (217 218–235)	Theoderic (1100)
Novatian (251)	Albert (1102)
Felix II (355–365)	Silvester IV (1105–11)
Ursinus (366–367)	Gregory VIII (1118–21)
Eulalius (418–419)	Celestine II (1124)
Laurentius (498–*c.* 505)	Anacletus II (1130–38)
Dioscorus (530)	Victor IV (Gregory) (1138)
Theodore (687)	Victor IV (Octavian) (1159–64)
Paschal (687)	Paschal III (1164–68)
Constantine II (767–768)	Calixtus III (1168–78)
Philip (768)	Innocent III (1179–80)
John (844)	Nicholas V (1328–30)
Anastasius (855)	Clement VII (1378–94)
Christopher (903–904)	Benedict XIII (1394–1423)
Boniface VII (974 and 984–985)	Alexander V (1409–10)
John XVI (997–998)	John XXIII (1410–15)
Gregory (1012)	Clement VIII (1423–29)
Benedict X (1058–59)	Benedict XIV (1425–30)
Honorius II (1061–72)	Felix V (1439–49)
Clement III (1080, 1084–1100)

ANTIPYRETICS are agents used to lower the temperature in fever. The most widely used group includes such drugs as antipyrine, acetanilid, phenacetin, quinine and the salicylates which increase heat loss by blood dilution and dilation of the skin capillaries, thus causing an increase in perspiration. Drugs may also produce a lowering in body temperature by dilation of the skin vessels (nitrites) or by slowing the circulation (aconite and veratrum). Heat loss may also be effected by such physical means as cold baths and ice packs.

ANTIQUE, a term meaning "old," but also carrying connotations of aesthetic, historic and financial value. Formerly it referred only to the remains of the classical cultures of Greece and Rome; gradually decorative arts, courtly, bourgeois and peasant,

of all past eras came to be considered antique.

Antiques have been variously defined by law for tariff purposes. Great Britain's customs and excise tariff law of 1959 specified: "To qualify for admission without payment of duty as an antique, an article must have been manufactured or produced as a whole, and in the form as imported, more than one hundred years before the date of importation." The same standard was set by most European countries. The Canadian customs tariff act in 1948 defined as antiquities "all objects for the adornment of mankind and his dwelling and all objects of educational value and museum interest, if produced prior to 1st January 1847." The United States tariff act of 1930 exempted from duty "Artistic antiquities, collections in illustration of the progress of the arts, objects of art of educational value or ornamental character . . . which shall have been produced prior to the year 1830 . . . ," a year widely accepted as proper because it marks approximately the end of traditional handicrafts and the beginning of industrialization. Industrial products at first were poor in design and in quality; attempting to recover earlier standards people became more and more interested in the products of ages past.

The collecting of antiques goes back almost as far as history, beginning with preservation of temple treasures. In England concern for the historical as well as aesthetic significance of antiques led, as early as the 16th century, to collections illustrating the national past; in subsequent centuries such collecting notably increased, stimulated by the rise of Romanticism and the start of archaeology. In 1857 the museum now called the Victoria and Albert opened in London as a repository for decorative arts, intended to stimulate designers as well as collectors. It was followed in 1863 by a great public collection in Vienna, in 1882 by the Musée des Arts Décoratifs in Paris and in 1897 by the Cooper Union Museum for the Arts of Decoration in New York. Antique collecting in the United States was given its first strong impetus by the Philadelphia Centennial exhibition, 1876, which awakened interest in the national past. Collecting antiques became a truly popular pursuit in the 20th century. Private collecting also influenced museum displays and stimulated the preservation, restoration and furnishing of historic buildings.

The design and construction of furniture, including that which would now be called "antique," is discussed in FURNITURE DESIGN and in articles about pieces of furniture. Similarly, other antique objects are discussed in various articles about the decorative arts, such as LACQUER; POTTERY AND PORCELAIN; GLASS; and others. *See* also ART FORGERY. (A. WI.)

ANTI-SEMITISM, consisting of hostile expressions or actions against Jews, has been a more or less constant feature of Jewish life in the Diaspora (*q.v.*). The term, apparently first coined by Wilhelm Marr or Ernest Renan in the 1870s, connoted the new forms of Jew-baiting generated during the era of Jewish emancipation, which stressed racial and socio-economic antagonisms above the religious issues which earlier had dominated Jewish-gentile controversies. Nevertheless, the heritage of ancient and medieval hostilities remained and coloured many arguments as well as legislative enactments.

The persistence of anti-Semitic feelings under various civilizations has been explained by a variety of psychological and sociological motivations. The general factors creating antagonisms among groups—such as dislike of the different, the search for scapegoats in periods of crisis and the tendency to generalize the shortcomings or transgressions of individuals and attribute them to the entire group—have been aggravated in the case of Jews by the heritage of religious hatreds and folkloristic superstitions. Jewish involvement in the crucifixion of Jesus and "stubborn" refusal to join the ranks of the majority were easily combined in the popular mind with an alleged Jewish alliance with the devil. Such alliance and the use of magic arts seemed also to explain the frequent successes in business and medicine by members of the "synagogue of Satan." These successes, moreover, often were an independent source of anti-Jewish feeling, especially among economic competitors and classes adversely affected by major economic changes. The frequent alliance of the Jewish communities with the ruling classes under whose protection they lived often brought down upon them the wrath of revolutionary groups, just as, conversely, in modern times the prominence of many Jewish leaders in leftist movements aroused the ire of many conservative elements and vested interests against the whole Jewish people. With the rise of modern nationalism, moreover, Jewish separatism and "unassimilability," as well as Jewish internationalism and "cosmopolitanism," became major targets for anti-Semitism. Racial anti-Semitism reached its climax during the period of Nazi domination over Germany, but it has continued since the downfall of Hitler despite the fairly unanimous repudiation by experts of the underlying biological theories.

EARLY MANIFESTATIONS

Anti-Jewish feeling appeared in ancient times. Sometimes this antagonism, shared by other minorities, assumed a specific character owing to the extraordinary situation and outlook of the Jewish people. In the book of Esther, Haman is reported to have underscored the Jews' unique distinctiveness among all the ethnic and religious groups inhabiting the Persian empire. This theme was taken up by a chorus of anti-Jewish writers in the Greco-Roman world, including the rhetorician Apollonius Molon, the rabble rouser Apion of Alexandria and even such Roman intellectuals as Cicero, Seneca and Tacitus. Seneca not only resented Jewish "separatism" but also the great influence of Judaism on his own compatriots. Juvenal actually attributed to Jews an unwavering hostility toward the whole outside world. Some of these concepts grew out of the clash between Hellenism and Judaism during the reign of Antiochus IV of Seleucid Syria, which led to the violent suppression of Jewish worship in Jerusalem and the ensuing Maccabaean revolt (165–140 B.C.; *see* MACCABEES). To justify the violation of the Jewish Temple, Seleucid propagandists invented stories about Jewish donkey worship and other allegedly barbaric Jewish rituals. These fables also laid the foundations for recurrent ritual murder accusations against both Jews and early Christians. Above all, the Jewish imageless worship found little understanding in the classical world. "They adore only clouds," exclaimed Juvenal, while others saw in the Jewish refusal to participate in the imperial worship, that main symbol of the unity of empire, utter lack of patriotism and, to use a modern term, a sign of divided loyalties. The frequently contradictory nature of these accusations, a permanent feature of anti-Semitic literature of all ages, was pointed out by Josephus (1st century A.D.) when he described Apollonius' *Diatribe Against the Jews* as "reviling us in one place as atheists and misanthropes, in another reproaching us as cowards, whereas elsewhere, on the contrary, he accuses us of temerity and reckless madness" (*Against Apion,* ii: 14, 148).

These religio-cultural controversies were aggravated by frequent political clashes. In its attempt to divide and rule, the Roman empire often protected the Jewish minority against the local majorities and even insisted upon a measure of equality of rights for the former. Particularly in Alexandria, the commercial and cultural metropolis of the eastern Mediterranean, the ruling classes contested the claim of the local Jewish community, probably the largest in the world, to Alexandrian citizenship. The ensuing controversies led to bloody outbreaks, sometimes followed by execution of the anti-Semitic ringleaders by the Roman authorities. They generated a Jewish apologetical literature culminating in Josephus' *Against Apion.*

Many arguments of the classical anti-Semites were taken over by the apologists of the nascent Christian church, although during the first three centuries it, too, felt the force of similar accusations by pagan rulers and writers, and was often more sharply persecuted than the Jews. Now, however, these denunciations were overshadowed by those relating to the specific Jewish "sin" of having crucified Christ and the assertion that Jews misinterpreted materialistically (*i.e.,* literally) the Old Testament passages foretelling the coming of the Messiah. Jews were also often accused of informing on their Christian compatriots to the Roman or Persian oppressors, as well as of undermining the faith of orthodox Christians by their own teachings and rituals.

Out of this array of accusations grew the demand for sharp

segregation between Jews and Christians. When after 313 the Christian faith became dominant in the Roman empire, ecclesiastical leaders inspired a long series of legislative enactments by Roman emperors designed to lower the status of the synagogue and its worshipers, to segregate Jews from believing Christians and to curtail Jewish religious self-determination where it might become a dangerous rival to ecclesiastical domination. In the laws of the Christian Roman empire and the contemporary patristic letters were laid down the principles of the Christian outlook on Jews and Judaism which were to colour the entire relationship between the two faiths in the middle ages and early modern times. For the first time the Jew was declared a permanent alien and wanderer who, because of his repudiation of Christ, had lost his home and was condemned to perpetual migration. While he was to be protected against total extinction to the end of days, when the second coming of Christ would be ushered in by the full conversion of Jews to Christianity, he was to be maintained in a status of legal and social inferiority and removed from close social contact with believers.

At times leading churchmen, such as St. John Chrysostom in the 5th century and Agobard, archbishop of Lyons, in the 9th, stressed the anti-Jewish more than the tolerant aspects of church doctrine. Agobard fulminated especially against the Jewish "superstitions" and the Jews' "insolent" domination of the economic and political life of the Carolingian empire. The distinguished medieval philosopher John Duns Scotus, admitting the necessity of preserving a Jewish remnant to the messianic era, suggested that a certain number of Jews be deported to a distant island and maintained there at Christianity's expense to the end of days. In view of the changed economic situation, in the later medieval period—when Christians increasingly participated in commerce, and money lending became a major Jewish enterprise—Jews were accused (*c.* 1140) by Peter the Venerable, abbot of Cluny, and others of usury and parasitic exploitation of the Christian population.

The masses went further. Envious of Jewish economic and cultural successes, they accused Jews of using magic arts as the willing associates of Satan. Not prepared to understand or accept the fine nuances of church doctrine, oscillating as it did between basic toleration and the lowering of Jewry's social standing, the masses often reacted violently by massacring Jews or by demanding their expulsion. Wherever total exclusion proved impracticable, Jews were often sharply segregated from the Christian population in quarters of their own and forced to wear the yellow badge (*see* GHETTO). From the 12th century (Norwich in 1144, Blois in 1171, etc.) the ancient ritual murder accusation reappeared with ever greater frequency (*see* HUMAN SACRIFICE: *Ritual Murder*).

These and other arguments, by constant reiteration, sank deeply into the minds of the Christian nations. In those countries which, like Germany and Poland, had not gone through the total expulsion of Jews and hence carried the ancient traditions of hostility in unbroken historic continuity, this was a particularly fateful heritage. Much of that heritage merely needed to be translated into modern secular terms to serve as incendiary material in the new secular environment of the emancipation era.

18TH AND 19TH CENTURIES

After the peace of Westphalia freedom of religion began to be increasingly accepted as a dominant principle of public law, and from that time the anti-Semites shifted their emphasis from the religious to the political and socio-economic issues. Most spokesmen of the Enlightenment era extolled the idea of mutual toleration. They began viewing Jews principally as individuals and members of humanity at large, and as such entitled to the rights of man. During the protracted debates on the Jewish question at the French national assembly in 1790–91 the opposition to Jewish equality of rights stressed either the social-cultural unassimilability of the Jews and their forever forming a "state within the state" (Abbé J. S. Maury and the conservative faction) or the Jewish economic "exploitation" of the peasantry (J. F. Reubell and other Alsatian radicals). Although repudiated by the French majority, these slogans influenced Napoleon's "Infamous Decree" of 1808. (*See* JEWS: *Modern Period: Period of Emancipation.*) They soon were echoed especially in Germany, where anti-Semitism achieved a new respectability and gained much popular support as part of the rising tide of German nationalism after the wars of liberation. Formulated by reputable academicians such as Friedrich Rühs and J. F. Fries, the idea that, despite emancipation, Jews could never become full-fledged members of the German nation eventually led to popular outbreaks in 1819.

In the following decades the various clerical parties used these arguments to rationalize their old religious antagonisms without incurring the odium of religious intolerance. The newly arising socialist parties, on the other hand, effectively employed them in their agitation against the established order. Viewing the Jews of western Europe as leading representatives of capitalist society, Charles Fourier and his disciple Alphonse Toussenel attacked Jewish economic domination (Toussenel's *Les Juifs, rois de l'époque*, published in 1846, strongly argued that point), while the then youthful Karl Marx, although himself born a Jew and descendant of a long line of rabbis, contended in 1843 that the Jews were but exponents of "civil society" (*bürgerliche Gesellschaft*) and, with the disappearance of the latter after the forthcoming victory of socialism, they, too, would vanish from the world scene.

New German Empire.—These anti-Semitic utterances and actions, however, did not crystallize into regular movements or into political parties with anti-Semitic programs. These emerged in Germany only after unification, very largely as a consequence of the ruin brought about by the financial crisis of 1873. In that year a Hamburg journalist, Wilhelm Marr, published *Der Sieg des Judenthums über das Germanenthum* ("The Victory of Judaism Over Germanism"; frequently reissued), which applied to the ancient prejudices a theory of nationality that, under the sponsorship of G. W. F. Hegel, had seized the minds of the German youth and to which the stirring events of 1870 had given practical significance. It also provided a welcome scapegoat for sufferers from the depression. The conservative and ultramontane press rang with the sins of the Jews, and in Oct. 1880 an anti-Semitic league was founded in Berlin and Dresden.

Leadership of the German agitation was assumed by Adolf Stöcker, one of the court preachers who had embraced the doctrines of Christian socialism and had formed a society called the Christian Social Workingman's union. He was also a Conservative member of the Prussian diet. Under his leadership the years 1880–81 became a period of bitter conflict with the Jews. The Conservatives supported him, partly because Christian socialism was likely to weaken the hold of the Social Democrats on the lower classes. Violent debates took place in the Prussian diet. A petition to exclude the Jews from the national schools and universities and to disqualify them from holding public appointments was presented to Bismarck. Jews were boycotted and insulted. Duels between Jews and anti-Semites, many of them fatal, became daily occurrences. On their side the Jews did not lack friends. The crown prince (afterward Emperor Frederick) and crown princess boldly set themselves at the head of the party of protest, the prince publicly declaring that the agitation was "a shame and a disgrace to Germany." A manifesto denouncing the movement as a blot on German culture, a danger to German unity and a flagrant injustice to the Jews themselves was signed by a long list of illustrious men.

The first severe blow suffered by the German anti-Semites was struck in 1881, when, to the indignation of the whole civilized world, the riots against the Jews in Russia and the revival of the medieval blood accusation in Hungary illustrated the incendiary nature of the new anti-Semitism. Some of the extremists among the racial anti-Semites began to extend their campaign against Judaism to its offspring, Christianity. In 1879 Johann Sepp, arguing that Jesus was of no human race, had proposed that Christianity should reject the Hebrew Scriptures and seek a fresh historical basis in the cuneiform inscriptions. Later Eugen Dühring in several brochures attacked Christianity as a manifestation of the Semitic spirit which was not compatible with the theological and ethical conceptions of the Germanic peoples. With these tendencies the Christian Socialists could have no sympathy, and

the consequence was that when in March 1881 a political organization of anti-Semitism was attempted, two rival bodies were created, the Deutsche Volksverein, under the conservative auspices of Liebermann von Sonnenberg, later author of the much-quoted *Beiträge zur Geschichte der antisemitischen Bewegung* ("Contributions to History of the Anti-Semitic Movement"), and the Soziale Reichsverein, led by the racial and radical anti-Semites Ernst Henrici and Otto Böckel. In 1886, at an anti-Semitic congress held at Kassel, a reunion was effected, but this lasted only three years. In June 1889 the anti-Semitic Christian Socialists under Stöcker again seceded.

During the subsequent ten years the movement became more and more discredited. Financial and other scandals covered the party with the very obloquy which it had attempted to attach to the Jews. At the same time, the Christian Socialists who had remained with the Conservative party also suffered. After the elections of 1893 Stöcker was dismissed from his post of court preacher. The following year the emperor publicly condemned Christian socialism and the "political pastors." Another blow to anti-Semitism came from the Roman Catholics. They had become alarmed by the unbridled violence of the demagogues, and in 1894 the ultramontane *Germania* publicly washed its hands of the Jew-baiters. Thus gradually German anti-Semitism became stripped of every adventitious alliance. At the general election of 1903 it managed to return only nine members to the *Reichstag*. Although in those years (1899) appeared Houston Stewart Chamberlain's *Die Grundlagen des neunzehnten Jahrhunderts* (*Foundations of the 19th Century*), which subsequently became a classic of racial anti-Semitism (*see* CHAMBERLAIN, HOUSTON STEWART), the fury of anti-Jewish agitation had spent itself without producing a single legislative enactment against the Jews, and that at a time when the second *Reich* was readily promulgating special legislation against Socialists, Catholics and Poles.

Austria-Hungary.—Understandably, the German-speaking areas in the neighbouring Habsburg empire were most immediately affected. Austrian anti-Semitism found influential spokesmen particularly among the pan-German nationalists and the Christian Socialists. Among the former it was the maverick deputy Georg von Schönerer who declared anti-Semitism as "the mainstay of our national ideology" and an integral part of the program of the newly formed German National party (beginning with the parliamentary elections of 1885). Stressing above all the racial issue, a member of that party, Josef Herzog, presented in parliament a bill amending the constitution of 1867 by withdrawing the equality of rights from "all members of the Jewish race, irrespective of their religion, whose descent from a Jew or Jewess could be proved either from the paternal or maternal side in the first, second, or third generation" (May 1, 1903).

By broadening its attacks to include also the Roman Catholic Church and the Habsburg monarchy, however, this vocal and much-publicized movement antagonized the masses of the Austrian Germans, who preferred the more moderate brand of anti-Semitism as preached by the Christian Socialist party. Aided by the debate on the *Talmudjude*, published by the Prague theologian August Rohling in 1874, the clerical Jew-baiters concentrated their assaults on the Jewish religion and way of life. Supported by the clerical paper the *Vaterland*, the Christian Socialist party celebrated many electoral victories. In 1895 its leader, Karl Lueger, a gifted demagogue, was elected mayor of Vienna, over the emperor's opposition. The party subsequently became the largest in the Austrian parliament. Although it thus became the first political party to achieve power with the aid of an avowedly anti-Semitic program, the Christian Socialist faction greatly moderated its policies with respect to both legislation and administrative practice. Its inconsistencies were well illustrated by Lueger's reputed declaration: "I decide who is or is not a Jew."

Russia.—The practical effects of the German anti-Semitic teachings on the political and social life of Russia were more serious. Medieval anti-Semitism was still an integral part of the polity of the Russian empire. The Jews were confined to one huge ghetto in the western provinces (*see* PALE). Their activity or exploitation, as it was called, was exaggerated and resented by the landowners who had been hurt by the emancipation of the serfs. A nationalist and reactionary agitation emanated particularly from the Slavophil party, which, under N. P. Ignatiev and K. P. Pobêdonostsev, became paramount in the government, with a policy based on absolutism, orthodoxy and the racial unity of the Russian people. The blood accusation also made sporadic appearances and even found an eloquent defender in the priest Hippolyte Liutostansky. This was the situation on the eve of Easter 1881. The hardening nationalism above, the increasing discontent below, Jewish economic activity and echoes of anti-Semitism from over the western border were combining for an explosion.

A scuffle in a tavern at Yelisavetgrad (Kirovograd) sufficed to ignite this combustible material. Within a few weeks the whole of western Russia from the Black sea to the Baltic was smoking with the ruins of Jewish homes. Murderous riots and incendiary outrages took place in no fewer than 167 towns and villages, including Warsaw, Odessa and Kiev. Instead of curbing these outbreaks, the police often disarmed Jews trying to organize in self-defense, while the courts later meted out light sentences to the ringleaders. The tsar's ministers, ardent Slavophils, were not slow to recognize in the outbreak an endorsement of the nationalist teaching of which they were the apostles, and, while condemning the acts of violence, came to the conclusion that the most reasonable solution was to aggravate the legal disabilities of the persecuted "heretics."

To this view the tsar was won over, partly by the clamorous indignation of western Europe, which had wounded his national *amour propre*, and partly by the strongly partisan report of a commission appointed to inquire into the exploitation alleged against the Jews. Its report resulted in the drafting of a "temporary order concerning the Jews" by the minister of the interior, which received the assent of the tsar on May 3, 1882. This order had the effect of creating a number of fresh ghettos within the pale of Jewish settlement. The Jews were driven into the towns and their rural holdings arbitrarily confiscated, with the result that their activities were completely paralyzed, and they fell into a condition of unparalleled misery. By stimulating Jewish emigration into the western countries, moreover, the new legislation played into the hands of anti-Semitic agitators there, who effectively exploited the xenophobic sentiments among the masses.

The Russian May laws were the most conspicuous legislative monument achieved by the new anti-Semitism up to that time. Their immediate result was, however, a commercial depression which was felt all over the empire and which profoundly affected the national credit. Negotiations for a large loan had been entered upon with the house of Rothschild, and a preliminary contract had been signed, when the finance minister was informed that unless the persecution of the Jews was stopped the great banking house would be compelled to withdraw from the operation. Deeply mortified by this attempt to deal with him *de puissance à puissance*, the tsar peremptorily broke off the negotiations and ordered that overtures be made to a non-Jewish French syndicate. In this way anti-Semitism, which had already profoundly influenced the domestic politics of Europe, set its mark on the international relations of the powers, for it was the urgent need of the Russian treasury quite as much as the termination of Bismarck's secret treaty of mutual neutrality which brought about the Franco-Russian alliance.

A new era of conflict dawned with the great constitutional struggle toward the end of the 19th century. By confining the Jews to the towns at the very moment when Count S. Y. Witte's policy of protection was creating an enormous industrial proletariat, the May laws placed at the disposal of the disaffected masses an ally powerful in numbers and intelligence. As early as 1885 Jewish workmen, assisted by Jewish university students, led the way in the formation of trade unions. They also became the colporteurs of western European socialism, and they played an important part in the organization of the Russian Social Democratic federation which their Arbeiter Bund joined in 1897. The latter ultimately counted 30,000 members. The Jewish element in the new democratic movement excited the resentment of the government, and the persecuting laws were once more rigorously en-

forced. They were not abolished until the Revolution of 1917.

Other Countries.—The only other country in Europe in which there had been legalized anti-Semitism was Rumania, where the struggle against Ottoman domination assumed the form of a crusade against Islam. Rumanian politicians preached a nationalism limited exclusively to indigenous Christians. Thus, although the Jews had been settled in the land for many centuries, they were by law declared aliens. This was done in defiance of the treaty of Paris of 1856 and the convention of 1858, which declared all Rumanians to be equal before the law, and also in violation of the treaty of Berlin of 1878 under which Rumania agreed to abolish religious disabilities. Despite reiterated interventions of the western powers, including Britain and the United States, it was not until 1919 that these violations were finally swept away.

The last country in Europe to make use of the teachings of German anti-Semitism in party politics was France. The movement became serious in 1882 when the failure of a prominent financial enterprise was blamed on Jews. In 1886 violent expression was given to that feeling in a book, *La France juive devant l'opinion*, by Édouard Drumont, which appeared in a hundred editions within a year and was speedily translated into English, Spanish, German and Polish. Before long all disaffected elements, especially in the army, joined the Boulangist movement, led by Gen. Georges Boulanger (*q.v.*).

In 1894 a prominent Jewish officer, Capt. Alfred Dreyfus (*q.v.*), was arrested on a charge of treason, and though the case against Dreyfus was proved false, public agitation continued long after his vindication, leaving permanent scars on French public life.

1901 THROUGH WORLD WAR II

At the turn of the century anti-Semitism increasingly assumed international aspects. Stöcker and his associates had tried in the 1880s to organize international congresses of the various Jew-baiting groups. These efforts were facilitated by the problems created by the Jewish mass migrations from eastern to western Europe and America, which reached a peak in 1890–1914. In the debates which preceded the enactment of the Anti-Alien laws in England (1903) and those accompanying the numerous hearings in the U.S. congress from 1891 on, the Jewish issue arose. At the same time the United States government insisted upon equal treatment of its Jewish and non-Jewish citizens in foreign countries. As a result of a long drawn-out controversy with the Russian regime, which discriminated against foreign Jews as it did against its own, Pres. William Howard Taft abrogated in 1912 the 80-year-old commercial treaty with Russia.

More generally, however, the ever-strengthening imperialist tensions which ultimately led to World War I helped the anti-Semites. Nationalist agitators in many countries increasingly attacked Jewish "internationalism" and the alleged alliance between the Jews and the internationally minded Freemasons. In 1906 Count Lamsdorf, the Russian foreign minister, actually suggested an alliance between the tsar, the German emperor and the pope to combat the Jewish "foe of the Christian and monarchical order in Europe." German nationalists, on the other hand, often viewed Christianity itself as a serious impediment to the realization of their imperialistic dreams.

In the meantime conditions in eastern Europe went from bad to worse. The regime of Nicholas II (1895–1917) not only intensified Russian legislative and administrative measures against the Jews but also actively promoted the spread of anti-Semitic propaganda. The tsar spent large sums from his personal funds to subsidize anti-Semitic publications, thus, ironically, indirectly inciting the populace to breaches of order. The militant League of the Russian People, formed in 1904 and popularly called the Black Hundreds, enjoyed the full backing of the government. The latter did nothing to prevent the recurrent violent outbreaks against Jews, culminating in the Kishinev massacre of 1903 and numerous pogroms in reprisal for the Jewish share in the revolution of 1905. Riots in Bialystok, Congress Poland, in 1906 simultaneously attested the effectiveness of the tsarist policies to divide its opponents. The growing tension between the nationalistic Poles and the Jews reached a peak in 1912, when the former proclaimed a sharp economic boycott on their Jewish compatriots.

All this was but a prelude, however, to World War I, which brought with it a series of political and economic changes that were bound to have their effect upon the attitude of the peoples of Europe toward the Jew. The war had marked the breakup of two great empires, tsarist Russia and Austria-Hungary. It was in this area that the largest number of Jews was concentrated, and there more than anywhere else that they maintained their distinctive Jewish way of life. Mob violence, arising from economic rivalry and religious bigotry, thus found in these areas an unprotected minority upon which to expend itself. There also were outbreaks against Jews during the postwar period in Algiers, Syria, Iraq and other Muslim areas.

One of the first phases of postwar anti-Semitism developed out of the Communist Revolution in Russia in 1917 and its aftermath in central Europe. The presence among Communist leaders of persons of Jewish extraction—such as Trotski, L. B. Kamenev, Grigori Zinoviev, Karl Radek and others in Russia, Kurt Eisner in Bavaria and Béla Kun in Hungary—provided anti-Jewish groups throughout the world with a new basis for their anti-Semitism. This was first made apparent in the civil wars between the Communists and the various White Russian armies that sought to overthrow the Red dictatorship. Wherever the White armies penetrated a wave of violence against Jews followed. The most serious excesses occurred in the Ukraine and White Russia, where the number of Jewish victims in 1918–19 far exceeded that of all the earlier pogroms since 1881. Reactionary forces in Europe and the United States, apprehensive of the spread of communist ideas from Russia, likewise identified communism with the Jews. This charge of "Jewish bolshevism" was later to be taken up by the German Nazis and made the cornerstone of their international propaganda. It mattered little that not only the vast Jewish middle class but also the Jewish-Socialist *Bund* sharply opposed communism. For every Jewish Communist leader could be counted several prominent Jewish Socialists who suffered imprisonment and exile as Russian "counter-revolutionaries." In fact, many Communist agitators were appealing to the working classes and lower middle classes by identifying Jews with capitalism and plutocracy.

Manifestations of anti-Semitism spread to the Anglo-Saxon countries. Books such as Lothrop Stoddard's *The Rising Tide of Color Against White World-Supremacy* (1920) and *Racial Realities in Europe* (1924) and Madison Grant's *The Passing of the Great Race* (1916) revived and popularized Nordic racial theories. The charges made against Jews by anti-Semitic writers and agitators revolved around three main points: (1) the claim that Jews were a disintegrating force in the political, moral and cultural life of the countries in which they resided; (2) charges of Jewish economic domination and monopoly; and (3) a claim of Jewish world conspiracy. (Paradoxically, the Nazis later sought to liquidate Jews because of Judaism's spiritual values and its vision of the universal relatedness of all human beings.)

Anti-Semitic writers concocted weird fantasies concerning the alleged Jewish world conspiracy. The most notorious of these fabrications is known as the *Protocols of the Learned Elders of Zion*, which purports to be a report of a series of 24 (in other versions, 27) meetings held at Basel, Switz., in 1897, at the time of the first Zionist congress. There plans were said to have been worked out whereby Jews, together with Freemasons, were to disrupt the entire Christian civilization, and on the ruins of Christendom erect a world state ruled over by Jews and Freemasons. The *Protocols* were first printed in Russia in abbreviated form in 1903 in the newspaper *Znamia* ("the Banner"), and subsequently in book form in 1905. They were translated into German, French, English and other languages of the western world and soon came to be the sacred book of anti-Semitic literature.

The spurious character of the *Protocols* was first revealed in 1921 by Philip Graves, Constantinople correspondent of the *Times* (London), who showed their obvious resemblance to a satire by Maurice Joly on Napoleon III published in 1864 and entitled *Dialogues aux enfers entre Machiavel et Montesquieu*. Subsequent investigation, particularly by Vladimir Burtseff, the historian of the Russian revolutionary movement, revealed that these *Proto-*

cols were forgeries, compounded by officials of the Russian secret police out of the satire of Joly, a fantastic novel *Biarritz* by Hermann Goedsche (1868), and other sources. John S. Curtiss, supported by a committee of prominent U.S. historians, published *An Appraisal of the Protocols of Zion* (1942) in which the documents are subjected to a thorough and critical analysis and pronounced to have no claim to authenticity.

National Socialism.—The storm of anti-Semitic violence let loose by the triumph of Adolf Hitler in 1933 not only reached a terrifying degree in Germany but inspired a world-wide anti-Jewish movement unequaled in modern history. Anti-Semitism ceased to be merely a local and internal problem; it became an instrument of German foreign policy and thus a problem of international concern.

The German revolution of 1918 had eliminated all forms of legal anti-Semitism under which the 500,000 Jews of Germany had lived in the second *Reich*. It was not until the rise of the Nationalsozialistische Deutsche Arbeiterpartei (NSDAP), led by Hitler, that anti-Semitism was made a major national issue by a political party. (*See* also NATIONAL SOCIALISM.) The novelty of this brand of anti-Semitism was that it appealed both to the underprivileged masses and to the élite of aristocrats, former army officers and bureaucrats displaced by the revolution. By stressing the pseudoscientific race theories of Count J. A. de Gobineau, Chamberlain, Dühring and Paul de Lagarde, it painted the "eternal" Jew as the permanent devilish enemy of the German nation. It combined these doctrines with elements in the philosophy of Nietzsche directed against the ethical and moral teachings of ancient Judaism and Christianity and with the neopaganism of Richard Wagner and others. The anthropological bases for these theories were developed by Ludwig Woltman, Ludwig Schemann and above all by the Nazi race theorist H. F. K. von Günther.

The political and cultural applications found their supreme expression in Hitler's *Mein Kampf* and in Alfred Rosenberg's *The Myth of the 20th Century*. A crude and pornographic form of anti-Semitic propaganda was carried on by Julius Streicher, through his *Der Stürmer* (founded in 1922), whose vulgar cartoons and illustrations incited its readers to violent actions against Jews and their non-Jewish friends. The maintenance of "Aryan" racial purity was asserted to be the main function of the state, since this was the only truly creative race in history and interbreeding tended to lead to its corruption. Of this Aryan race the Germans were said to be the purest examples, although scientists pointed out that "Aryan" refers to a family of languages used by many peoples and that there is no such thing as an Aryan race.

Anti-Semitism in Germany also derived from other sources. The Communist Revolution brought German free corps soldiers fighting side by side with the White armies, and a great deal of anti-Semitism filtered into Germany by this route. Hitler's views, too, were coloured by his contact with anti-Semitic currents in Vienna before World War I. Finally, the pacifist activities of such German Jews as Kurt Eisner infuriated the German nationalists and enabled them to identify Judaism with pacifism.

With the coming to power of the Nazis, a flood of anti-Semitic propaganda was loosed. A boycott of Jewish shops was organized on April 1, 1933, and carried out chiefly by the SA (*Sturmabteilungen*). This was to serve as the symbol of popular pressure for legal action against Jews. A decree of April 7, 1933, forbade non-Aryans to occupy public posts, except those who had been in office before Aug. 1, 1914, or who had served in World War I. These exceptions were revoked in 1935. A non-Aryan was defined as a person having at least one Jewish grandparent. This Aryan paragraph was soon applied to the fields of culture and the liberal professions. Jews were dismissed from their posts in universities and technical schools; Jewish artists, musicians, actors and screen and radio stars (with special exceptions) were banned from appearances before German audiences, and Jews were eliminated from the field of journalism.

The denial to Jews of German citizenship was accomplished by the Nürnberg laws on citizenship and race of Sept. 15, 1935, art. ii declaring: "A citizen of the reich is only that subject who is of German or kindred blood and who, through his conduct, shows that he is both desirous and fit to serve faithfully the German people and the reich." In the first supplementary decree of Nov. 14, 1935, this was made specific by defining who was a Jew and by declaring explicitly that "a Jew cannot be a citizen of the reich. He cannot exercise the right to vote; he cannot occupy public office." Together with this law came another designed to complete the process of Jewish segregation. Marriages and extramarital relations between Jews and "Aryans" were prohibited. Jews were also forbidden "to employ in domestic service female subjects of German or kindred blood who are under the age of 45 years." Before long Jewish passports were stamped with a red "J" (*Jude*), and Jews were compelled to adopt Jewish names. Jewish communities were deprived of their legal status by the decree of March 28, 1938, and steps were taken to exclude Jews completely from the practice of medicine.

A high point in Nazi anti-Semitic activity in Germany was reached in the pogroms of Nov. 1938. On Nov. 7 a 17-year-old Polish Jewish boy, Herschel Grynszpan, assassinated one of the junior counsellors to the German embassy in Paris, Ernst vom Rath. This act set off, on the night of Nov. 9, a systematic series of violent reprisal actions by the Nazis. Jewish homes and shops in Germany were plundered. More than 30,000 arrests were made and thousands of Jews sent to concentration camps. Synagogues in Germany and Austria (about 600) were methodically set on fire and the holy scrolls desecrated. Jewish orphanages, homes for the aged and hospitals were not spared. These acts were carried out by the SA, SS (*Schutzstaffel*), Hitler Youth and the gestapo (*Geheime Staatspolizei*) without the participation or sympathy of the general populace. The decrees of Nov. 12 and Nov. 23, 1938, completed the total elimination of Jews from German economic life, while imposing upon them the enormous fine of 1,000,000,000 marks ($400,000,000).

The triumph of national socialism in Germany and the adoption of anti-Semitism as the official government policy brought about a tragic deterioration of the position of Jews far beyond the German frontiers. The main centres for the international dissemination of anti-Semitism, utilizing all the varied arts of propaganda, were Fichte-Bund in Hamburg, Reich Institute for the Study of the Jewish Question and, above all, Welt-Dienst in Erfurt.

The dumping of many German and Austrian refugees into the western countries, which had just begun to recuperate from the great depression of the early 1930s, and the deportation of thousands of Polish Jews to Poland in 1939 likewise helped to increase anti-Jewish feelings. A foreign office circular sent to all German legations and consulates on Jan. 23, 1939, emphasized that "the poorer and therefore the more burdensome the immigrant Jews are to the country absorbing them, the stronger that country will react and the more favourable will the effect be in the interest of German propaganda." In 1933 the Nazi regime also began sponsoring international congresses of anti-Semites (Copenhagen in 1933, Budapest in 1934 and Erfurt in 1937). Most significantly, anti-Semitism became an integral part of German foreign policy. Anti-Semitic propaganda, by increasing domestic unrest and partisan strife, weakened the powers of resistance of Germany's neighbours and prepared them for Nazi conquest.

The Nürnberg war crimes trials and many publications issued after 1945 recalled the appalling extent of anti-Semitic activities during World War II. By 1943 Hitler's *Festung Europa* was dotted with concentration and labour camps, and mass deportations to these centres were being carried out from all the occupied countries (*see* CONCENTRATION CAMPS). Wherever there was any sizable Jewish population, the entry of the Nazis was marked by mass pogroms and organized murder on a scale previously unheard of. Lwow (Lvov), Pol., for example, had 160,000 Jewish residents when it was captured on June 29, 1941; only about 827 came out of hiding after the Russians returned three years later. Of the 3,300,000 Jews in Poland at the outbreak of the war, not more than 10% were alive in 1944, including the refugees to the Soviet Union and other countries.

Despite the enormous number of documents available, it is difficult to fix exactly the date of the Nazi decision to speed the process of population extermination. Gas vans, gas chambers and lethal injections were already in wide use in Europe at the end

of 1941, when the Nazi administration built its large death installations at Auschwitz (Oswiecim; *q.v.*), Chelm, Belzec, Bergen-Belsen, Buchenwald, Dachau (*q.v.*), Maidanek and Treblinka. A major decision using veiled language was taken in the Gross-Wannsee conference of Jan. 20, 1942. In March 1943 the first crematorium was opened at Maidanek. At several death centres, notably Auschwitz and Buchenwald, finely equipped hospital laboratories were maintained in which medical experiments were conducted upon living men and women. The record of German atrocities in France, compiled by the supreme Allied headquarters' psychological warfare section, filled 13 volumes.

Perhaps six out of every seven European Jews found in the occupied areas were killed by the Nazis. This figure must be viewed in the context of the wholesale extermination of "undesirable" ethnic, national and religious groups. It is estimated that from 18,000,000 to 26,000,000 persons—prisoners of war, political prisoners, men, women, children of all ages and all nationalities—were "put to death by the Germans through hunger, cold, pestilence, torture, medical experimentation, and other means of extermination in all the camps of Germany and the occupied territories" (***Documents pour servir à l'histoire de la guerre***, vol. iv, "Camps de concentration," Office Français d'Edition, Paris, 1945).

Not all opposition to Nazi anti-Jewish excesses was crushed, however. Even in Germany, many Jews owed their lives to their Christian neighbours, who sheltered them or their children. Some Protestants and Roman Catholics in Germany consistently opposed Nazism, and such opposition was stronger in the occupied countries. In the spring of 1943, for example, the *Bratislava Gardista* grumbled that "anti-Jewish action in Slovakia is not meeting with the expected success," and the *Grenzbote* accused Slovaks of widespread collusion with the Jews. Louis d'Arquier de Pellepoix, French commissar for Jewish affairs, admitted that resistance to anti-Semitic measures in France continued strong despite threats of punishment. Because thousands of Jewish children were being hidden by non-Jews that spring, the gestapo was extending its raids into the homes of peasants in French areas formerly unoccupied. In Denmark, eight bishops protested against anti-Semitic propaganda to Minister of Justice Thune Jacobsen, and clergymen everywhere, though forbidden to refer to the political aspects of the "Jewish problem," were outspokenly denouncing anti-Semitism. In Greece 600 priests were sent to concentration camps for refusing to preach anti-Jewish sermons and for urging their congregations to help Jews. Thirty-four Budapest residents were sent to prison for sheltering Jews, and some Christian Hungarian women openly wore yellow badges in contempt of the regime's anti-Jewish decrees. The Protestant and Catholic churches of the Netherlands protested the persecution of Jews and the deportation of Dutch citizens. Swedish condemnation of Hitler's "barbaric and systematic extermination of the Jews" continued, and the director of the Swedish Red Cross resigned in protest against the refusal of the Nazis to allow the organization to send aid to Jewish women and children in Poland or to permit the emigration to Sweden of Norwegian Jewish families whose men had been deported.

Among the Jewish victims themselves, resistance was sporadic, desperate and futile. There were many tragic gestures of heroic defiance, notably the uprising in the Warsaw ghetto. At its most crowded stage this ghetto, a slum area of Warsaw which had originally housed about 50,000, contained more than 450,000 Jews from all parts of conquered Europe. By April 1943 their numbers had been reduced to 35,000 by mass executions, pestilence, starvation and deportation to the death camps. On April 18, the eve of Passover, armed with a few rifles, hand grenades and machine guns obtained from the Polish underground, the Jews of the Warsaw ghetto gave battle to the German army, and 25,000 perished.

United States.—After the colonial period, religious freedom, reflecting the need for unity among the various groups in the population, became a dominant principle of American public life. Jews were accorded the same dignity and rights as persons of other religions. To be sure, events in Europe awoke echoes: the Dreyfus case caused talk; the faked *Protocols of the Learned Elders of Zion* were published in Henry Ford's *Dearborn Independent* and elsewhere; and the Ku Klux Klan in the 1920s included anti-Jewish with its stronger anti-Roman Catholic and anti-Negro phobias. But anti-Semitism was not virulent in the United States before Hitler's triumph in Germany, when Nazi propaganda found a depression-born climate of opinion favourable to intergroup hostilities.

The German-American Bunds, directed from Germany, although their total membership amounted to only 8,300 in 1939, possessed more than 80 active cells, including 22 youth camps located near important military centres. The Nazis embraced other organizers who appealed for membership with an anti-Semitic line: William Dudley Pelley started the Silver Shirts in North Carolina in the early 1930s; the Reverend Gerald B. Winrod began operations for Defenders of the Christian Faith in Kansas about the same time, with anti-Semitism as the core; George Deatherage brought the Knights of the White Camellia into action; the Black legion, the Sentinels of the Republic, the American Vigilant Intelligence federation and the Christian Front were other units carrying the Nazi philosophy. The last organization centred around Father C. E. Coughlin of Royal Oak, Mich., and his publication *Social Justice;* in radio talks he used familiar anti-Semitic phrases.

A new element, however, served as a check to anti-Semitism—the National Conference of Christians and Jews, founded in 1928 by Charles Evans Hughes, Newton D. Baker, S. Parkes Cadman, Roger W. Straus and Carlton J. H. Hayes. More importantly, apart from being shocked by the Nazi atrocities, American public opinion increasingly resented Hitler's expansionist policies. Ultimately the United States was drawn into the anti-axis alliance, which made pro-Nazi propaganda of any kind extremely suspect.

Canada.—In Canada, too, organized anti-Semitism began to flourish only after Hitler's seizure of power. More than 20 anti-Semitic organizations sprang up between 1933 and 1935. In Quebec the Parti National Social Chrétien, modeled after the German NSDAP, was organized by Adrien Arcand, the *führer* of Canadian fascism. There also were Blue Shirts, White Shirts and other Jew-baiting groups. Anti-Semitism was frequently condemned by powerful voluntary organizations, however, and anti-Jewish manifestations were relatively quiescent during World War II.

Great Britain.—In England Sir Oswald Mosley's British Union of Fascists carried on a wide variety of anti-Jewish activities, from demonstrations in the Jewish districts of London to the dissemination of the *Protocols* and other pamphlets and leaflets. Even more extreme was the National Socialist league, formed by John Becket and William Joyce (the notorious Lord Haw-Haw of the German broadcasts during World War II), and the Imperial Fascist league, headed by Arnold Leese. These activities met with strong opposition, however, from government spokesmen and leaders of British public opinion.

Western Europe.—Italy, although totalitarian before Germany, was practically free from anti-Semitism until it became enmeshed in German foreign policy. The first legal measures against Jews were initiated in Sept. 1938, and the basic anti-Jewish legislation was incorporated in the racial laws, patterned on the Nürnberg laws, of Nov. 17, 1938. These measures found little support among the Italian people and, aided by Christian neighbours, three-quarters of Italian Jewry survived the Nazi ordeal.

In France the coming to power of a popular front government headed by a Jew, Léon Blum, was utilized by the anti-Semitic groups to raise a cry of Jewish domination and Jewish communism. With the heightening of the international crisis, particularly after the pact of Munich in 1938, anti-Semitic agitation in France became closely identified with a pro-Nazi orientation of French foreign policy and came to be considered a serious menace to the safety of the state. After the German conquest the formal distinction existing up to Nov. 1942 between the occupied and unoccupied zones was reflected in the attitude toward the Jews. In the occupied zone confiscations and "Aryanization" of Jewish property, anti-Jewish legislation and physical assault upon Jews followed the regular pattern of Nazi Germany proper. In the unoccupied zone the status of the Jews depended largely on the degree of Franco-German collaboration. As the Vichy regime became more and more committed to a policy of collaboration, the

severity of the measures against the Jews increased, and were extended to the colonial empire. In all the territories adhering to Gen. Charles de Gaulle and the Fighting French and, after the Anglo-U.S. occupation, also in north Africa, these anti-Semitic measures, together with all Vichy legislation, were declared null and void. This administrative division helped some two-thirds of the Jews of metropolitan France to survive, whereas neighbouring Belgium lost more than half and the Netherlands more than three-quarters of their Jewish inhabitants.

In Norway the clergy of the state church, under the leadership of the courageous Bishop Eivind Berggrav, opposed the Nazi propaganda, and a pastoral letter was read in many churches denouncing the racial legislation. From its office in London, the Norwegian government in exile opposed the agitation against Jews in Norway. In Denmark the adamant stand of King Christian succeeded in preventing special anti-Jewish measures demanded by the Nazis during the occupation. Many Danish Jews fled to Sweden, assisted by Christian Danes. In Sweden the activities of the anti-Semitic editor Einar Aberg were of minor importance.

In Switzerland, too, there were many expressions of disapproval of Hitler's anti-Jewish policy throughout the whole Nazi era, although there appeared numerous publications which attempted to justify the Nazi party line.

Eastern Europe.—In sharp contrast with the policies of the other states of eastern and central Europe was the original public stand against anti-Semitism taken by the Soviet Union. Lenin and his associates included the Soviet Jews among the national minorities to which the law of Nov. 1917 promised full governmental support in the preservation of their cultural autonomy; they also outlawed anti-Semitism and declared it to be a counter-revolutionary crime (July 1918). To reinforce this prohibition Lenin himself broadcast to the Soviet peoples a major message explaining that anyone urging discrimination against Jews unwittingly promoted the restoration of the tsarist regime. This policy was more or less strictly adhered to, although the simultaneous prohibition of Zionism, the elimination of public instruction in Hebrew and the agitation against Jewish religion were sapping the vitality of the Russian Jewish community, which became increasingly isolated from the rest of world Jewry. Moreover, Stalin constantly reiterated his view that the recognition of national minority rights was intended only for the period of transition from the capitalist to the truly communist society. In the 1930s, owing to the rising wave of Russian nationalism and imperialism, this friendly attitude toward the Jewish community underwent a change. It reached its nadir after the conclusion of the German-Soviet treaty of nonaggression in 1939, followed by the incorporation of some 2,500,000 Jews in the newly occupied territories of Poland and the Baltic states. However, after the German invasion of Russia the Soviet regime again professed its friendliness toward the Jewish people and through the Anti-Fascist league tried to collaborate with the Jews of other countries.

In Poland, after World War I, the lead in the anti-Semitic movement was taken by the old National Democratic party (known as Endeks). The economic crisis helped to create a favourable environment for anti-Semitism, which took the form of physical attacks upon Jews and student riots in the universities, and above all in the economic boycott of Jewish business enterprises and Jewish professionals. The period of violent assaults upon Jews came to an end in 1926 with the coup d'état of Marshal Jozef Pilsudski, and until his death in 1935 Pilsudski's dictatorial regime protected the Jews from mob violence. The economic strangulation continued, however, and increased nationalization of the Polish economy resulted in the elimination of thousands of Jewish workers from industry. The death of Marshal Pilsudski opened the way for a new wave of anti-Semitism. The worsening economic conditions, the coming to power of the clique of Polish colonels, and the flirtation of Foreign Minister Jozef Beck with Nazi Germany all helped to aggravate the situation. Extremist parties, such as the National Democrats and the Nara (National Radicals), began to emulate Nazi policies toward the Jews. Jewish ritual slaughtering was outlawed in 1936. Universities practised an informal *numerus clausus;* many established special "ghetto benches" for Jewish students. Violence once more became widespread, the economic boycott was extended and there was agitation for the emigration of "superfluous" Jews. Elimination of Jews from the economic and professional life of Poland continued. Within a few weeks after Hitler's armies had moved into Poland, ghettos were established and large numbers of Jews were deported or sent into forced labour and concentration camps. Terrorism became the official policy.

Before World War I, Hungary was relatively free of radical anti-Semitism, and for the most part the Jews were accepted as loyal citizens of the realm. The economic dislocation of the postwar period, however, and also the fact that the Hungarian Communist revolution of 1919 was led by Béla Kun, who was born a Jew, resulted in the growth of animosity which, ushered in by the White Terror and propagated by the Awakening Magyars, placed Hungary with Poland and Rumania as the three countries in which anti-Semitism was widespread before the advent of Nazism. Acts of violence were committed, a silent effective boycott was instituted against all Jews, particularly in the smaller towns and villages, and Hungary was the first country in postwar Europe to pass a *numerus clausus* law, restricting the number of Jewish students in the universities to 5% (1920). This law was in violation of Hungary's obligation assumed in the postwar treaties, and aroused considerable opposition in international circles, but it was not modified until 1928. Hitler's triumph in Germany led to the rapid spread of Nazi agitation in Hungary, and only the fact that occupation of Hungary by German troops was delayed enabled about half the Jewish population (in the 1937 boundaries) to escape the Nazi extermination squads.

In Rumania anti-Semitism was widespread during the period 1918–35. There were practically no Jews in the civil service, and they were discouraged from entering the professions. Both the National Christian party and the Liberal party were anti-Semitic, and the National Peasant party, coming into power in 1928 after a record of disavowal of anti-Semitism, did nothing to change the situation. As Rumania came into the political orbit of Nazi Germany the condition of the Jews worsened, and Nazi officials established close connections with the native anti-Semitic groups, especially the Iron Guard. Nevertheless, because of greater laxity in execution, more than half of Rumanian Jewry either survived the war in the homeland or returned there from the concentration camps in Transnistria. (K. S. P.; E. R. Cy.; B. Y. L.; S. W. B.)

AFTER WORLD WAR II

After the Nazi defeat in World War II the anti-Semitic movement lost ground in western Europe and America, but as a result of international developments it assumed new significance in the Soviet Union, eastern Europe and the middle east. Its new manifestations were partly the aftermath of the Nazi regime and partly the result of the new enmities generated by the rise of the state of Israel.

Germany and Western Europe.—In the first years after the war the Jewish issue was kept alive in Germany and throughout formerly Nazi-occupied Europe by the recurrent war crimes trials, the denazification procedures, property restitution problems and the attempts at rehabilitating the survivors of the Nazi concentration camps. The International Military tribunal at Nürnberg in 1945–46 tried 22 "major war criminals." By dealing with such leading Nazis as Hermann Göring and Joachim von Ribbentrop, by defining the nature of crimes against humanity as well as war crimes and crimes against peace, and by accumulating an enormous mass of written and oral testimony, it established a standard for similar trials by other tribunals, both national and international. By its detailed account of the persecution of the Jews and its finding that half the defendants were guilty of crimes against humanity for participating in these atrocities, it brought to public attention the enormity of the mass murder of Jews committed during the war. When the United Nations War Crimes commission came to an end in 1948, jurisdiction over these offenses was transferred to the individual countries, where public opinion veered toward increasing leniency. (*See* WAR CRIMES.)

The denazification proceedings aimed at removing confirmed

Nazis from administrative and teaching posts in Germany faced the difficulty of distinguishing ideological from prudential Nazis and of conducting administration without the services of many of the latter class. By 1955 most denazification courts had altogether suspended their activities. The problem of former Nazis in political and administrative offices became, indeed, one of the outstanding issues in West German public life in the 1950s and 1960s. As an indication of the number of these, by Sept. 1962, 149 of West Germany's 11,500 judges and prosecutors had taken advantage of a law of June 1961 permitting early retirement for those who had been in office during the Nazi period. Various attempts to re-establish formal neo-Nazi parties in West Germany failed, in part because of their outlawry by the courts and in part because of lack of popular support. Certain crypto-Nazi groups and parties could claim some members, but they were politically negligible.

In East Germany many former Nazis became Communists. In Nov. 1951 some 900 former Nazis in East Berlin were allowed to establish the People's Freedom party.

The rehabilitation of the survivors of the concentration camps and efforts at restitution of confiscated Jewish property were attacked by neo-Nazi agitators in the West German republic. Many Germans who had acquired from the Nazis confiscated Jewish houses, factories and other businesses were reluctant to return them to their rightful owners, and formed protective associations to resist restitution. Within a decade after the war, however, all the camps for displaced persons had been emptied of their Jewish inmates by emigration to Israel, the United States and other countries. The last camp, at Föhrenbach, was closed in 1956. Restitution and reparation proceedings likewise proceeded with respect to individual claimants as well as to the vast property to which there were no heirs. They culminated in the Luxembourg agreement of Sept. 10, 1952, between Germany, on the one hand, and the state of Israel and the Conference on Jewish Material Claims Against Germany, representing the leading Jewish organizations in the free world, on the other hand, whereby Germany promised to deliver to Israel in the course of 12 to 14 years goods valued at $822,000,000 (of which $107,000,000 was to be used for the indemnification of Jewish victims residing outside Israel). This agreement as well as internationally supported attempts at restoring Jewish property in other formerly Nazi-occupied countries were cited by anti-Semitic agitators as proofs of Jewish world machinations. Incidents affecting Jewish war orphans served to embitter relations between Jews and their neighbours. Foster parents who had saved Jewish children whose parents had been deported, and raised them in the Christian faith, on several occasions defied court orders to restore the children to their Jewish relatives. All through these years anti-Semitic propaganda continued.

The most persistent Jew-baiting French periodicals, the weekly *Aspects de France*, *Rivarol* and *La Nation française*, in the early 1960s had a combined circulation of only 105,000. The monthly *Défense de l'Occident* and *Europe Action* (the latter launched in Jan. 1963) had much smaller circulations. Politically, anti-Semitism was ineffective in France after World War II, in spite of the possibilities opened up by the powerful right-wing surge during the Algerian war and by the brief prominence of Pierre Poujade's tax-protest movement (he won 12.1% of the vote in the parliamentary elections of Jan. 1956).

Apart from local anti-Semitic publications there was a considerable interterritorial exchange of Jew-baiting literature. The Swedish pro-Nazi Einar Aberg attracted particular attention in Europe and America, although his influence in the Scandinavian countries was negligible, particularly after he was condemned to prison in June 1954. A Russian *émigré* group in Munich, the St. George's Brotherhood for National and Patriotic Enlightenment (RONDD), likewise had an extensive mailing list in many countries. The international congress of anti-Semites meeting in Malmö, Swed., in 1951, attracted more notice because of its disavowal of Nazi affiliations than because of its representative character.

Behind the "Iron Curtain."—A sharp turn toward anti-Semitism occurred in the Soviet Union and its European satellites beginning in 1948. With the progressive deterioration of inter-Allied relations and the outbreak of the Korean War, the Soviet Union began to view the Jewish population as a potentially subversive group. Journalistic spokesmen for the regime, including the Jew Ilya Ehrenburg, began attacking the Jews for their "cosmopolitanism" and their connections with western co-religionists. Although in Nov. 1947 the Soviet Union joined the United States and other powers in voting at the United Nations for the partition of Palestine and the establishment of the state of Israel (Soviet main interest being to remove British influence from the middle east), the U.S.S.R. distrusted Russian Jewry's "nationalistic" attachment to the new state. These accusations were followed by the deportation of thousands of Jews, including most Yiddish writers and other intellectuals, to Siberian labour camps. All organs of Jewish opinion and almost all Jewish cultural institutions were closed. In 1952 Jews were withdrawn from the Soviet army of occupation in East Germany, and the *Big Soviet Encyclopaedia* dropped the names of Jewish scientists, writers and artists listed in the 1947 edition. Finally, a number of leading Jewish doctors in Moscow were accused of plotting to poison Stalin and other leaders. The evidently intended large-scale persecution of Jews was interrupted, however, by Stalin's death (1953). The new regime thereupon declared the doctors to have been victims of charges falsified by L. P. Beria, head of the secret police. The ensuing relaxation of anti-Jewish agitation, however, was neither all-embracing nor enduring.

Though the Soviet government has been consistently hostile to all religions, it seemed clear during the late 1950s and 1960s that a policy to obliterate not only the practice of Judaism but also Jewish culture was in operation. Jewish congregations were not permitted to form regional or national associations; necessary religious articles could not be manufactured; facilities for rabbinical training were practically eliminated; and the Hebrew language, essential for understanding and participating in religious services, could not be taught (as it had not been since 1917). Participation by Jews in public life likewise was being curtailed. In May 1961 the death penalty was extended to "economic crimes"; by March 1963, 58 trials had been held for such crimes, more than half of them involving Jews. Newspaper reports of the trials made a point of emphasizing defendants' Jewishness by dwelling on Jewish-sounding names, etc.

Among the satellite countries, Poland and Rumania maintained their deep-rooted anti-Semitic heritage. Although the Jewish population of Poland had dwindled to some 90,000 (in the new geographic boundaries) in 1945, the animosities, strengthened by resentment of claims for restitution of property made by the few Jews who returned from the Soviet Union, led to numerous riots, culminating in the Kielce pogrom of July 1946. More than 800 Jews lost their lives in the first two years after the liberation. The government, in which the Communists played an increasingly dominant role, at first opposed anti-Semitism and supported the newly formed League to Combat Racism. But this very attitude, combined with the presence of a number of Jews in the highest echelons of the Polish Communist party, intensified the anti-Jewish agitation among rightist groups. By 1948, however, when the Communists secured full control, the Soviet attitude was fully adopted, leading to persecution of Zionists and suppression of most Jewish cultural activities. Jewish "nationalism" was now equated with "anti-gentilism." This policy of suppression was moderated slightly upon the return of Wladyslaw Gomulka to power in 1956 and the adoption of a somewhat more independent policy toward the Soviet regime, although this upheaval had also resulted in the demotion of several influential Jewish Stalinists. The 20th anniversary of the uprising of the Warsaw ghetto was celebrated solemnly throughout Poland in 1963, with the government participating.

In Rumania, too, the progressive seizure of power by the Communists was accompanied by the persecution of "Zionists" and the suppression of all Jewish cultural activity. The early rush of Jewish *émigrés* to Israel was checked, and thousands of Zionist leaders were condemned to long prison terms. Ultimately, leading

Jewish Communists, among them the foreign minister, Ana Pauker, were removed from office. But in Rumania, too, the death of Stalin led to some moderation of the anti-Jewish policies.

Equally reflective of the changing Soviet policies were those pursued by Czechoslovakia and Hungary. In Slovakia the heritage of the Tiso regime led to many assaults on Jews in Bratislava and elsewhere in the first postwar years. In Bohemia and Moravia, on the other hand, the Jews were often accused of having been agents of Germanization. The restitution of Jewish property was opposed not only by the new owners but also by labour unions and the bureaucracy, which wished to maintain state ownership of expropriated holdings. Under the influence of the Soviet policies, finally the numerous Jews serving in the Communist party leadership, diplomatic posts, etc., lost their positions, and some even their lives. The trial and execution in Nov. 1952 of Rudolf Slánsky, the former secretary of the party, and several of his Jewish associates had overtly anti-Semitic aspects.

In Hungary similar developments were aggravated by numerous deportations of citizens from Budapest and provincial cities to labour camps in the Soviet Union in 1951–52. These exiles included a disproportionate number of Jews (in Dec. 1951 the Vatican radio estimated that there had been 14,000 Jews among the 38,000 deportees from Budapest alone). Jews also comprised a very large proportion of victims of the successive Communist purges and of the repression of the Hungarian revolt of 1956, although many thousands succeeded in escaping. A similar exodus had taken place from East Germany, especially the eastern sector of Berlin, in 1953, when anti-Jewish purges had revealed that that country, too, had subscribed to policies of the U.S.S.R.

Middle East.—Since the Arabs regard themselves as Semites, Arab hostility to Israel is primarily political, a result of the territorial and refugee problems, and not racial. It resulted, however, not only in a world-wide anti-Zionist propaganda but also in many anti-Jewish measures because of the assumption that Jews generally support Zionism. Under the guise of suppressing illegal Zionism the Iraqi and Syrian governments instituted a persecution of all Jews. As a result of the ensuing mass migrations, the Jewish population in Iraq dwindled from 130,000 to 6,000 and that of Syria from 25,000 to 3,000 in the first four years after the rise of the new state. In Egypt, where even the revolutionary regime of Gamal Abd-al-Nasser professed to distinguish sharply between Jews and Zionists, all restraints were removed during the Sinai campaign in the autumn of 1956. Confiscations of Jewish property and more or less enforced emigration further reduced the number of Jewish inhabitants, which had already dwindled from 75,000 in 1946 to 35,000 in 1953; by 1963 Jews in Egypt were estimated to number no more than 4,000.

At the same time the various propaganda services of the Arab league in the western countries often indulged in accusations against Jews and Judaism generally and in many cases worked with local anti-Semites. Some Arab nationalists felt that by thus undermining the power and influence of the local Jewish communities they might weaken the support extended to Israel by the western powers. The member states of the Arab league also proclaimed an economic boycott of Israel and even boycotted firms trading with the new state.

South Africa.—In South Africa the Jewish population was menaced, many leaders of the dominant Nationalist party having made anti-Jewish and pro-Nazi statements before and during the war. However, the government of Daniel Malan, soon after coming to power (1948), reassured the Jewish citizens that it intended to adhere scrupulously to the principle of constitutional equality. An official list of 2,300 prohibited publications issued in July 1956 included the *Protocols* and several other anti-Semitic tracts. The government's growing friendship with Israel, since both countries felt threatened by the African and pan-Arab propaganda emanating from Egypt, also benefited the local Jewish population. But in 1961 Israel joined the Afro-Asian states and the Soviet bloc in a UN General Assembly motion to censure South Africa for its *apartheid* policy, and thereafter relations between the two countries deteriorated. Though the South African government made a firm distinction between the country's Jewish community and the state of Israel, and made pronouncements against anti-Semitism that were generally supported, anti-Semitic groups increased their activities, especially through circulation of Einar Aberg pamphlets.

Western Hemisphere and British Commonwealth.—In the United States anti-Semitic agitation by what Pres. Franklin D. Roosevelt had called the "lunatic fringe" greatly diminished after the war. William Dudley Pelley was sentenced to a prison term of 15 years. The German Bund disintegrated, although there were still a few attempts to revive its Nazi program. However, there was a fairly steady flow of anti-Jewish periodicals and pamphlets, most persistently those of Gerald L. K. Smith and Conde McGinley, leader of the *Common Sense* group of Union, N.J., both of whom supplied hate literature to other organizations.

The intensification of the movement for Negro civil rights in the late 1950s and 1960s created tensions and disturbances that provided good ground for a resurgence of anti-Semitic activity. Especially prominent was the American Nazi party, whose anti-Semitic publications were numerous and virulent. But U.S. anti-Semitism more typically expressed itself under guises of patriotism or religiosity, or both, and these were seen in the activities of the Ku Klux Klan; the National States Rights party, with its monthly *Thunderbolt* and reprints of such classical anti-Semitic literature as Arnold Leese's *Jewish Ritual Murder* and the *Protocols of the Learned Elders of Zion;* and the National Renaissance party, headed by James H. Madole, with its bimonthly *National Renaissance Bulletin.*

Native Argentinian anti-Semitism received a new impetus from the immigration of numerous Nazis, for whom the country became a major haven of refuge and who propagated their violent brand of anti-Semitism in a periodical, *Der Weg.* They found a few listeners. However, even the Perón administration refrained from enacting any discriminatory legislation against Jews, and the later more liberal regimes adhered to the principle of Jewish equality. In the 1960s, however, a strong wave of anti-Semitism swept Argentina, the result of several factors chief of which was undoubtedly the kidnapping of Adolf Eichmann by Israeli authorities, in violation of Argentinian territorial integrity. This created resentment, and a number of anti-Semitic outrages followed. In the week after Eichmann's execution (May 31, 1962) ten serious incidents occurred. Most of these could be traced to adolescent members of two neo-Fascist organizations, Tacuara and Guardia Restauradora Nacionalista, which in May 1963 were banned.

Elsewhere in Latin America, anti-Semitism has never been prominent, even in such countries as Uruguay, Brazil and Mexico, which have sizable Jewish populations. The 1962 incidents in Argentina touched off a few minor outrages in Brazil and Uruguay against which measures were promptly taken.

The Jewish populations of the British Commonwealth suffered relatively little from anti-Semitism, despite tension in regard to the Palestine situation in 1946–48. Occasional outrages, such as damage to several synagogues in and around London on the night of the Day of Atonement, 1948, were generally condemned by public opinion. In the summer of 1962 disorders took place in Trafalgar square, London, during meetings of Colin Jordan's National Socialist movement, Sir Oswald Mosley's Union movement and Andrew Fountaine's British National party, the three main fascist organizations in Britain. As a result of a police raid on the National Socialist movement headquarters thereafter, Jordan and three supporters were convicted of violating the Public Order act and sentenced to prison terms. The conviction, on appeal, was sustained by the High court in March 1963, the Lord Chief Justice, Lord Parker, declaring that guarantees of free speech do not include the right to "threaten, be abusive or insult [others] in the sense of hitting them by words." His decision led to debate over the desirability of further legislation to curb hate groups.

In Canada, notwithstanding the dissemination of much anti-Jewish literature, both native and imported, several provincial legislatures passed laws prohibiting discrimination in employment, and generously responded to appeals for immigration of Hungarian refugees, including Jews. In Australia the earlier opposition to Jewish immigration gave way to a friendly attitude that found

expression in the rejection by the vast majority of the occasional anti-Jewish publications, chief among which were those of Eric Butler's Social Credit movement and the *New Times* magazine.

ANTISEPTICS. Antiseptics are a group of widely differing chemical compounds possessing the property of either killing bacteria (bactericidal) or of preventing their multiplication (bacteriostatic). They are employed in medical practice with the object of preventing or combating bacterial infection of superficial tissues, and in the sterilization of instruments and infected material. A distinction is drawn in modern usage between antiseptics and chemotherapeutic agents, such as the antibiotics, sulfonamides and organic arsenical drugs, which are administered by mouth or by injection for the treatment of deep-seated or generalized infections but may also be applied locally in the treatment or prevention of superficial infections.

The first rational use of a chemical substance to prevent or control infection in the human body occurred when Joseph Lister (later Lord Lister), following the demonstrations by Louis Pasteur that fermentation and putrefaction were caused by living bacteria or yeasts, conceived the idea of interposing an antiseptic barrier between injured tissues and the germs that might gain access from an outside source. Lister employed carbolic acid in various forms both to control infection of intentional or accidental wounds and to sterilize surgical instruments. He thereby greatly reduced the risks and deaths from hospital sepsis. In hospital practice this principle of antisepsis was modified in favour of asepsis, in which potentially dangerous germs are denied access to susceptible tissues by the sterilization, usually by heat, of all instruments and dressings, the wearing of sterile gowns, masks and rubber gloves, and the disinfecting by chemical antiseptics of the skin around the site of operation.

Properties of Antiseptics.—A very large number of chemical compounds possess the power of killing bacteria, but many of them also exhibit properties that may profoundly affect or entirely prohibit their practical use. Most antiseptics are general protoplasmic poisons and if used in sufficient concentration are harmful to the body's cells and tissues as well as to bacteria. Thus an antiseptic is most valuable in the disinfection of contaminated wounds or skin surfaces when there is a wide margin between its bactericidal and toxic concentrations. When, however, an antiseptic is to be used to disinfect contaminated articles or excreta, its toxic properties are not important, and so chemical substances (usually called disinfectants) may be used for this latter purpose that cannot be applied to living tissues.

Again, the activity of antiseptics, with the possible exception of the acridine dyes, is adversely affected by the presence of organic matter such as blood or serum. The degree of inactivation varies with different compounds and with the quantity of such material that is present. It is perhaps the most important factor contributing to the difficulty of controlling wound infection by the application of antiseptics.

Another difficulty is that different species of bacteria show great variation in their sensitivity to antiseptics in general or to any particular antiseptic; among the more resistant are the tubercle bacillus, bacterial spores and the blue pus bacillus, *Pseudomonas pyocyanea*, which prove very troublesome in superficial wounds and burns.

Evaluation and Comparison of Antiseptics.—The efficiency of an antiseptic must be measured in relation to three main factors: concentration, time and temperature. It is desirable to know the minimum concentration at which an antiseptic will be effective. Some antiseptics like phenol lose their activity sharply beyond a certain dilution, whereas mercurial preparations are still inhibitory to bacterial growth at very high dilutions. The time that an antiseptic takes to act will depend to some extent on its concentration, but the speed at which antiseptics kill bacteria varies considerably; thus the halogens (*e.g.*, iodine and chlorine salts) act quickly while the mercurials, the compounds of heavy metals and the antiseptic dyes are slowly acting antiseptics. Most antiseptics act more quickly with increase of temperature; *e.g.*, the activity of the coal tar derivatives is doubled by a rise in temperature from that of a cool room to body heat. Hypochlorites, on the other hand, are best used cold since they become more unstable at higher temperatures.

Many attempts have been made to produce a satisfactory standard method of comparison of antiseptics. None of these is entirely satisfactory owing to the impossibility of selecting a single yardstick by which the performance of an antiseptic under widely differing conditions may be judged. The best-known comparative tests are the classical methods developed by S. Rideal and J. T. A. Walker (1903) and the modified test introduced by H. Chick and C. J. Martin (1908; see *Bibliography*). The principle employed in the Rideal-Walker method is the determination of the concentration of antiseptic that will kill a suspension of the typhoid bacillus in a given time, compared with the killing efficiency of phenol under similar conditions. The bactericidal activity of the antiseptic under test may then be expressed as a figure of 2,5,10, etc. (the phenol coefficient), relative to the

efficiency of phenol, which is represented as unity. The Chick-Martin test employs a similar technique but is modified by the addition of known quantities of organic material. The inherent disadvantage of any such tests is that efficiency is only measured against one organism under a single set of conditions. Results show considerable variation if these conditions are altered and the test gives little guidance about how an antiseptic may be expected to act under practical conditions.

The more modern approach to the problem makes use of *in vivo* tests, in addition to test-tube methods, and thus tries to imitate the natural conditions that may be met in practice. For example, several antiseptics may be compared for their efficiency as skin disinfectants by tests on the skin of volunteers for such qualities as lethal effect against a wide range of organisms, speed and reliability of action and the absence of irritant effects on the skin.

Use and Choice of Antiseptics.—If the antiseptic is to be used to disinfect instruments or infected material its toxicity is of minor importance and high concentrations may be used. Speed and efficiency of action and cost are the main considerations.

On the other hand, for the disinfecting of skin and in the treatment or prophylaxis of wound infection, the degree of inactivation by organic material, the duration of effective action, the powers of penetration, and activity against a wide range of bacteria are of major importance. Certain antiseptics, for example, 2% iodine and 70% ethyl alcohol, are particularly useful for the rapid and effective disinfection of the intact skin surfaces before operation or injection; the antiseptic dyes such as the flavines may be used effectively in surgical wounds and minor injuries to prevent the establishing of infection. Once infection has occurred in an open wound antiseptics are much less effective, for though they may produce a fall in the number of bacteria, they usually lack the ability to penetrate into the depths of the wound where bacterial growth is taking place. Besides, by inactivating the phagocytes and young tissue cells, antiseptics may interfere with the body's natural defenses and repair processes.

It is because they have the properties of diffusion and lack of toxicity to living tissues and are not inactivated by organic matter that penicillin and sulfonamide preparations have yielded such excellent results when applied directly in the prevention and treatment of wound infection.

Types of Antiseptics.—Antiseptics in common use fall into nine main classes.

Acids and alkalis are of little practical importance because they are either too caustic to tissues or are relatively inefficient bactericides. Acetic acid (vinegar), used for many centuries for dressing wounds, is a possible exception.

Soaps and Detergents.—The soaps possess both a bactericidal and cleansing action and are of considerable value when used to prevent superficial infection, since thorough washing of the skin results in a great diminution of the bacterial flora. Certain antiseptics, *e.g.*, hexachlorophene, may be incorporated in soaps.

Detergents are of three types, the anionic, cationic and nonionic. The cationic detergents exhibit powerful antiseptic properties and are active against most types of bacteria, particularly the pyogenic cocci. They are relatively nontoxic when applied superficially, but a minority of people develop skin sensitivity to them. These cationic detergents combine cleansing with bactericidal activity but have the disadvantage that they are inactivated by soap and are partially inactivated by organic material.

Oxidizing Agents.—This group, of which the more important members are potassium permanganate and hydrogen peroxide, owe their activity to the liberation of oxygen. Their chief disadvantage is the high degree of inactivation by organic material. Because of this and its instability in weak solution, hydrogen peroxide is a relatively poor antiseptic.

The halogens, chlorine and iodine, are both extremely effective agents and may be used in high dilution in the absence of organic material. The hypochlorites, which are marketed in many proprietary preparations, owe their activity to the liberation of chlorine, which acts as an oxidizing agent; they are quickly inactivated by organic matter. Iodine, though toxic to living tissue, provides the most efficient form of skin disinfection, particularly when combined with 70% ethyl alcohol. Iodoform has been used for wound disinfection but is ineffective.

The Heavy Metals.—The salts of mercury, silver, copper and zinc have been used as antiseptics. The simple salts of mercury are unsuitable for use in wound prophylaxis or therapy because they are toxic if used in bactericidal concentration and are only bacteriostatic in lower concentrations.

Complex organic mercury salts are more effective bactericides than the simple salts, are less affected by organic material, are less toxic and may have some prophylactic value when applied to wounds.

Ethyl alcohol is an excellent skin antiseptic, used in a 70% concentration with water. Industrial methylated spirit is 90%–95% alcohol and should therefore be diluted to 70% for most effective use; its use as an antiseptic for the storage of insulin or other hypodermic syringes is not recommended, since sterilization cannot be guaranteed.

The Coal Tar Derivatives.—This group contains a large number of common antiseptics and disinfectants varying considerably in toxicity and efficiency. Phenol, or carbolic acid, is the least efficient and is highly toxic to tissues. The cresols, which are various forms of methylated phenol, are poorly soluble in water but are dissolved in soap; they are somewhat stronger bactericides than phenol but only slightly less toxic. The black and white fluids are cresols, dissolved respectively in oils or gums, and are used mostly for the disinfection of excreta or contaminated materials. Xylenol, especially when combined with chlorine, is an effective general bactericide and is relatively nontoxic but is considerably affected by organic matter.

The Dyes.—The aniline dyes (*e.g.*, brilliant green, gentian and crystal violet) are slow-acting antiseptics with considerable penetrative power but are rather selective in their activity and are toxic to tissues.

The acridine dyes (*e.g.*, the flavines) also act slowly but they are practically nontoxic and are inactivated very slightly by organic material. They have been proved effective against infection of experimental wounds and have enjoyed considerable popularity in the control of wound infection.

Formalin (40% formaldehyde), sulfur dioxide and chlorine are employed in gaseous form for the fumigation of sick rooms, the so-called terminal disinfection. Formalin vapour is a very efficient surface disinfectant for bedding, books and other articles and materials that may be deleteriously affected by heat sterilization. Care must be taken to maintain a sufficient concentration of the gas for a sufficient length of time by sealing all air outlets in the room or chamber where the materials or articles are being disinfected. A moist atmosphere and higher temperatures enhance its disinfectant action.

Sulfur dioxide is less effective, and chlorine may tarnish or bleach.

Disinfection of polluted air by the administration in gaseous form of certain chemical substances (*e.g.*, hypochlorite, resorcinol or hexyl-resorcinol, glycols, lactic acid and its analogues) has not proved to be a practical proposition.

Germicidal and Fungicidal Lamps.—The most suitable electromagnetic radiation for use in germicidal and fungicidal lamps is ultraviolet in the region of 2650 Å. The most practical sources are low-pressure mercury vapour lamps, made of glasses capable of transmitting ultraviolet, which have a peak emission (about 95%) in the 2537 Å wave band. Quartz glass may also be used but requires screening with other types of glass or a jacket of acetic acid solution to prevent the emission of ozone-producing wavelengths shorter than 2000 Å.

Hot cathode lamps are of a construction similar to standard fluorescent lamps and require the same electrical circuits for their operation. Their life is dependent on the life of the electrodes and the transparency of the glass. Cold cathode lamps require high voltages for starting and operating and, as the electrodes do not require heating, their life is long. High intensity lamps combine the characteristics of the other two, requiring high voltages for starting and subsequently operating with hot cathodes. Their principal advantage is their high ultraviolet output per rated lamp watt, which is almost double that of the hot cathode tube; however, they share the same tendency to deteriorate.

Clinical Application.—The germicidal properties of ultraviolet lamps help to control cross-infection by the sterilization of air, the aim being to administer a lethal dose of radiation to the maximum number of air-borne organisms without endangering human skin or eyes. This cannot be achieved satisfactorily by total irradiation of a room or part of a room, but some success has been obtained by placing high-intensity ultraviolet sources at points of maximum air movement. The most popular application is the "ultraviolet curtain" across passages and doors, while organisms within the room are affected by the rapid recirculation of the room air past a shielded ultraviolet source.

(H. M. D.)

ANTISTHENES (d. *c.* 365 B.C. at an advanced age), Greek philosopher, of Athens, seems to have been converted from the study of rhetoric to that of philosophy by the influence of his friend Socrates. Tradition affirmed that Antisthenes taught in an exercise place called Cynosarges, being debarred as the son of a Thracian mother from other Athenian gymnasiums; and that for this reason his philosophy was called Cynicism (*see* CYNICS). The real inventor of the Cynic way of life was Diogenes, but he acknowledged an indebtedness to Antisthenes, whose views on morality he presumably learned from his numerous writings. Antisthenes was a true Socratic in maintaining the supreme value of virtue and that it could be taught, but he was more individual in welcoming his own poverty as giving freedom and in condemning all pleasure but the satisfaction of hard work.

That he held up Hercules and Cyrus as models is an example of his custom of turning mythology to edification, some of which found its way into the commentaries on Homer. As a Socratic, he became interested in the nature of definition and, more widely, in the possibility of significant predication. The grounds for his extreme views ("it is not possible to contradict") can only be guessed at; modern writers have called in aid various passages in Plato which they suppose to allude to him. (F. H. SH.)

ANTISTROPHE. The ancient Greek choral ode (*q.v.*), which has been imitated in modern European languages, is composed of one or more sets of three "stanzas" named strophe, antistrophe and epode. The strophe and antistrophe are of identical metrical structure.

ANTITOXIN, a substance present in the bloodstream which combats and neutralizes the toxins (poisons) produced by microorganisms. The inoculation of man, and a variety of experimental animals, with toxin or toxoid (a toxin in which toxicity has been destroyed but which still retains its antigenic properties) results in the appearance, three to five weeks later, of a capacity of the blood serum specifically to neutralize the toxin (*q.v.*). This capacity is demonstrable in the living animal as an immunity to the effects of an amount of toxin lethal to the normal animal; it is also demonstrable by mixing a lethal dose of toxin with immune serum in a test tube and then inoculating an animal with the mixture to show that it is no longer toxic (*see* IMMUNITY AND IMMUNIZATION).

The ability of the serum to neutralize toxin is attributable to the presence of a new substance, antitoxin. Antitoxin, like other antibodies, is usually associated with the gamma globulin fraction of serum protein and is produced in response to the antigenic stimulus provided by the inoculation of toxin or toxoid. This stimulus alters the normal processes of synthesis of globulin; the globulin is modified in such a way that it combines specifically with the toxin to give a complex that precipitates in the test tube (toxin-antitoxin flocculation) and is no longer toxic. This modified serum globulin is antitoxin. The presence of the appropriate antitoxin in the blood and other body tissues results in an effective immunity to the toxemias caused by bacteria, especially diphtheria and tetanus (*qq.v.*).

Man may form his own antitoxin in response to inoculation with toxoid (active immunity), or he may be made temporarily passively immune by inoculation with antitoxic serum taken from an immunized animal.

See IMMUNITY AND IMMUNIZATION; SERUM THERAPY; TOXIN; VACCINATION; VACCINE THERAPY; VENOM; *see* also references under "Antitoxin" in the Index.

ANTIUM: *see* ANZIO.

ANTLER, the name given to the solid bony outgrowths on the heads of deer, which are shed and renewed each year. For details *see* DEER.

ANT LION, the name given to insects (order Neuroptera) of the family Myrmeleonidae, with relatively short and clubbed antennae and four narrow, densely net-veined wings which are usually marked with brown or black. The adult insects are mostly nocturnal and are believed to be carnivorous. In the United States, where the ant lion is locally known as doodlebug, about 65 species occur. The best-known species, *Myrmeleon formicarius*, which matures in the late summer, occurs in many European countries, though like the rest of this group it does not occur in England.

Strictly speaking, however, the term "ant lion" applies to the larval form because of its peculiar and forbidding appearance and its skilful and unique manner of trapping prey by means of a pitfall. The sandy-gray abdomen is oval and covered with warts and bristles; the prothorax forms a mobile neck for the large square head, which carries a pair of long and powerful toothed mandibles.

The ant lion lays its trap in dry and sandy soil. Having marked out the chosen site by a circular groove, it starts to crawl backward, using its abdomen as a plow to shovel up the soil. By the aid of one front leg it places consecutive heaps of loosened particles upon its head, then with a smart jerk throws each little pile clear of the scene of operations. Proceeding thus, it gradually works its way from the circumference toward the centre. When this is reached and the pit completed, the larva settles down at the bottom, buried in the soil with only the jaws projecting above the surface. Since the sides of the pit consist of loose sand they afford an insecure foothold to any small insect that ventures over the edge. Slipping to the bottom, the prey is immediately seized by the lurking ant lion; or if it gains a hold and attempts to scramble up the treacherous walls of the pit, it is speedily checked in its efforts and brought down by showers of loose sand which are tossed at it from below by the larva. By means of similar head jerks the skins of insects sucked dry of their contents are thrown out of the pit. A full-grown larva digs a pit about two inches deep and three inches wide at the edge.

The larva makes a globular case of sand stuck together with fine silk, spun, it is said, from a slender spinneret at the posterior end of the body. It remains in this cocoon until the completion of the transformation into the sexually mature insect, which then

ANT LION (MYRMELEON FORMICARIUS) IN TWO STAGES OF ITS DEVELOPMENT: (LEFT) THE LARVAL STAGE; (RIGHT) THE PUPAL STAGE DURING WHICH THE PUPA MATURES WITHIN A BALL OF SAND OF ITS OWN MAKING

emerges from the case, leaving the pupal skin behind.

In certain species of Myrmeleonidae, such as *Dendroleon panthernis*, the larva, although resembling that of *Myrmeleon* structurally, makes no pitfall, but seizes passing prey from any nook or crevice in which it shelters.

ANTOFAGASTA, a province in the desert of northern Chile. Area: 48,381 sq.mi. It was occupied in 1879 by Chilean forces at the outset of the War of the Pacific, ceded by Bolivia in 1884 and created a Chilean province four years later. Present boundaries were fixed in 1938. Pop. (1960) 215,376 with about a third concentrated in the capital city of Antofagasta. Lesser administrative and urban centres are Tocopilla (pop. [1960] 21,580), Calama (26,166) and Taltal (5,291). The province leads Chile in mining, production in the early 1960s being valued at about 35% of national output. Copper from Chuquicamata (*q.v.*) and nitrates and iodine from María Elena and Pedro de Valdivia represent major portions of Chilean production, as does the production of sulfur, guano, gold and silver.

The Inter-American highway, air service and railways link the province with the rest of Chile. Railways also enter Bolivia and Argentina.

See also ATACAMA DESERT. (J. T.)

ANTOFAGASTA, capital of the northern province and department of the same name, and a major Pacific port. Pop. (1960) 87,860. Prior to 1879 it was in Bolivian territory. The city occupies a terrace at the base of bleak coastal mountains. Early growth resulted from the nitrate boom that began in 1868 and from the Caracoles silver strike of 1870, the year in which Antofagasta's name became official. Supplying the mines and embarking copper and sulfur continue to be major functions of the city. Besides foundries and shops, ore concentrating and sulfuric acid manufacturing facilities, the city's industry is concerned with food and beverage processing and fish-meal production. Rail communications with the mines date from 1873. Extension of the service to Oruro, Bol., occurred in 1879. In 1910 the railway was linked to the main Chilean system; in 1948 a line was opened into the Argentinian northwest with the hope of drawing food supplies and transit freight to the port city. One of Antofagasta's best-known institutions is the school of mines, founded in 1918. A turf club, modern hotel, municipal beach and various public gardens are tourist attractions. (J. T.)

ANTOINE, ANDRÉ (1858–1943), French actor, manager and critic, was born at Limoges and in his early years was a clerk. But he was an enthusiastic amateur actor, and in 1887 he founded in Paris the Théâtre Libre ("free theatre") in order to realize his ideas as to the proper development of dramatic art. In this undertaking he had the support of Emile Zola, who championed Antoine's efforts for the replacement on the Parisian stage of the "well-made play" by something nearer the actualities of life. Many other writers backed the campaign, and Antoine began to produce the great series of naturalistic plays by Eugène Brieux, François de Curel, Georges de Porto-Riche and Ibsen that made his theatre famous.

Great as was the Théâtre Libre's importance in Paris and in France, it was perhaps still greater in other countries. The Freie Bühne of Berlin, the Independent theatre in London and other such institutions descended from it. For an account of his work *see* DRAMA: *Modern Drama: Ibsen: The Play of Ideas.*

In 1894 Antoine gave up the direction of the Théâtre Libre to become connected with the Gymnase. Later, after a season (1896) with the Odéon, he opened his own theatre, the Théâtre Antoine, in 1897. He again became associated with the Odéon in 1906, but in 1913 resigned to become a drama critic. He died in Brestin, Brittany, Oct. 21, 1943.

See S. M. Waxman, *Antoine and the Théâtre Libre* (1926).

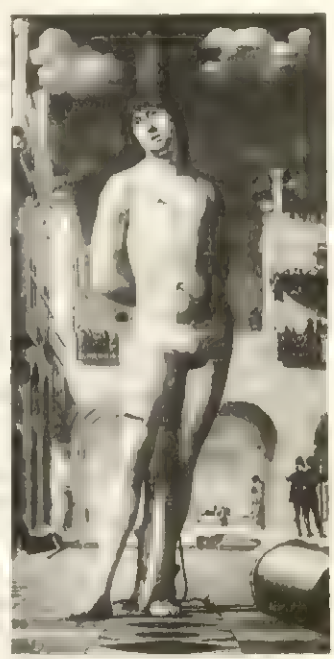
ANTONELLI, GIACOMO (1806–1876), Italian cardinal, secretary of state to Pope Pius IX (*q.v.*), was born at Sonnino on April 2, 1806. He entered public affairs and held various offices in the papal states. Though never ordained priest, he was created cardinal by Pius IX in 1847, and became in 1848 premier of the papal states, which were then for the first time governed by a democratic constitution. After his own and succeeding governments had fallen and the revolutionary situation at Rome had led to the assassination of Pellegrino Rossi in 1848, he showed much courage in remaining with Pius IX at the Quirinal and in planning the pope's flight to Gaeta, where Antonelli was made acting secretary of state.

After the pope's return to Rome in 1850, Antonelli was appointed officially to the post of secretary of state, which he retained until his death. He remained in general control of the government of the papal states until their elimination in 1870, and he was in charge of the pope's relations with other governments until 1876. His policy was to avoid further attempts to introduce constitutional government into the papal states, because it was impossible either to distinguish the pope's spiritual from his temporal power or to subject the former to a lay assembly. As an able diplomatic opportunist Antonelli knew that his only hope of preserving the pope's temporal sovereignty over central Italy during the growing movement for Italian unity was to retain the good will of the French government of Napoleon III, which had retained a garrison in Rome after 1850. He was therefore opposed to the raising of a papal army which took place in 1860, and to all quarrels, even of a religious character, with Paris. When the Piedmontese forces entered Rome in Sept. 1870 he requested them to extend their occupation to the "Leonine city" around the Vatican, to preserve order, and the papal army was disbanded.

He died in the Vatican on Nov. 6, 1876. Though he served the pope with great loyalty for nearly 30 years, and foreign diplomats paid tribute to his courtesy and good sense, Antonelli was little mourned by the better men at Rome. The pope himself had come to dislike him because of the frequent reports of the impurity of his life, while the wealth which he had accumulated, especially in his collection of precious stones, had caused offense to many. (E. E. Y. H.)

ANTONELLO DA MESSINA (*c.* 1430–1479), Italian painter, who greatly influenced the Venetian school of the early Renaissance, partly by his use of Flemish technique, was born probably about 1430 in Messina, Sicily. He received his training in Naples from Colantonio, whose art was based on Flemish and Provençal models, and studied Flemish works (notably of Jan van Eyck), of whose presence in Naples at that time there is documentary evidence; the influence of Jean Fouquet, Piero della Francesca and Spanish painting may also be assumed. On the other hand, the Netherlands visit affirmed by G. Vasari and the suggested encounter with Petrus Christus in Milan in 1456 may be ruled out. The earliest known works, a "Crucifixion" (Sibiu) and "St. Jerome in His Study" (National gallery, London), already show Antonello's characteristic combination of Flemish technique and realism with clarity and simplicity of spatial arrangement and modeling in the Italian manner.

From 1457 to 1474 Antonello is known to have been in Messina. In his earliest dated and signed work, the "Salvator Mundi" of 1465 (National gallery, London), his style is fully developed. A number of renderings of "Ecce Homo," the "Madonna and Child" in Washington, D.C., the "Virgin of the Annunciation" in Munich and in Palermo and several vigorous male portraits date from between 1470 and 1474. The chief works of this period are the polyptych of 1473 for S. Gregorio (Messina) and the "Annunciation" of 1474 (Syracuse). Of two "Crucifixions," both with landscape backgrounds, dated



ALINARI

"ST. SEBASTIAN" BY ANTONELLO DA MESSINA. IN THE GEMÄLDEGALERIE, DRESDEN, GERMANY

1475, the one in the National gallery, London, was probably painted in Sicily and that in the Antwerp museum, in Venice.

From 1475 to 1476 Antonello was in Venice and Milan. His altarpiece for S. Cassiano in Venice, fragments of which are in the Vienna museum, clearly influenced Venetian painters. The "Dead Christ With Angels" (Venice), some portraits and the full-length "St. Sebastian" (Dresden) were done in Venice. In the "St. Sebastian," his most mature work, Antonello achieved a synthesis of clearly defined space, monumental, plastic form and luminous colour, which was one of the most decisive influences on the evolution of Venetian painting down to Giorgione's day. In 1477 he was again in Messina, where he died between Feb. 14 and 25, 1479.

ANTONESCU, ION (1882–1946), Rumanian army officer and statesman, head of the pro-German government during World War II, was born at Pitesti on June 15, 1882. After service in World War I, he was military attaché in Paris and later in London. He returned to Rumania in 1930 and for a year (1934) was chief of the general staff. His nationalist and anti-Communist sentiments led him to sympathy with the anti-Semitic National Christian party of Octavian Goga and even with the Iron Guard of C. Zelea Codreanu. Appointed minister of defense in the Goga cabinet in Dec. 1937, he retained the post in Miron Cristea's government (Feb. 1938), but was dropped a month later because of his Guardist leanings. The territorial losses imposed on Rumania in 1940 by the U.S.S.R., Germany and Italy, before Rumania's entry into World War II, led to disorders and undermined the position of King Carol, who appointed Antonescu prime minister on Sept. 4, 1940, as a known patriot who was yet acceptable to the Germans. Antonescu agreed on condition that Carol abdicate in favour of his son Michael, and Antonescu became *conducator* of Rumania. At first he worked with the Guardists, but their excesses roused indignation, and in Jan. 1941 he crushed them (with the help of the German troops that he had allowed into Rumania as "instructors"). Having signed the Tripartite pact in Nov. 1940, he declared war on the U.S.S.R. as Germany's ally in June 1941, becoming himself generalissimo. The country supported his campaign for the recovery of Bessarabia, but there was opposition to his creation of a Rumanian province (Transnistria) on Ukrainian territory. In Aug. 1941 he was made marshal. With the success of the Soviet counter offensive in 1944, Rumanian circles opposed to Antonescu started secret negotiations with the Allies. King Michael had him arrested during his *coup d'état* of Aug. 23, 1944. Sentenced to death as a war criminal by the Rumanian Communist people's court, Antonescu was executed near Ft. Jilava on June 1, 1946. (B. BR.)

ANTONINE WALL, a Roman frontier barrier in Britain, extending for 36½ mi. across Scotland from Bridgeness on the Firth of Forth to Old Kilpatrick on the river Clyde, was built in A.D. 142 for the emperor Antoninus Pius by Lollius Urbicus, governor of Britain. Built of coursed turfwork on a kerbed rubble bottoming, it was 14–16 ft. wide and probably 10 ft. high, exclusive of any timber crenelation. A ditch 40 ft. wide and over 12 ft. deep ran 20 ft. or more in front, and about 50 yd. to the rear was a military road.

The wall was controlled from a series of 19 forts placed at intervals of roughly two miles; also from fortlets, four of which are now known. Two pairs of stances for fire signals faced north toward Stirling, one pair south toward mid-Clydesdale. The flanks of the wall were guarded by forts at Cramond and Inveresk on the Forth, and at Bishopton, north of Paisley, on the Clyde, while at Lurg moor, south of Gourock, there was a signal station. A road ran northward as far as Perth equipped with signal stations and forts; the wall was thus the base of a line of penetration which secured Fife and watched Strathmore.

The wall was built by the 2nd, 6th and 20th legions. It was garrisoned by auxiliary units, sometimes part mounted and sometimes subdivided among the smaller forts, from which combined sallies could trap attackers against the barrier. Occupation was interrupted during the northern revolt of 155–158; and the wall said by Dio Cassius (*Historia Romana*, lxxii, 8) to have been broken by enemy attack in 184 was probably this one. It was systematically evacuated not later than 196. Archaeologists have found evidence of one complete reconstruction, and occasional signs of a second; but historical correlation has yet been achieved only at Mumrills, linking the first reconstruction with the events of 155–158.

ANTONINUS, SAINT (ANTONIO PIEROZZI or DE' FORCIGLIONI) (1389–1459), archbishop of Florence, theologian and economist, is regarded as one of the founders of modern moral theology and Christian social ethics. Born in Florence, he there joined the Dominican order (1405), in which he became a leader of the Observant movement, especially at Fiesole. As vicar of the Observants he founded the convent of San Marco, Florence, in 1436 and was prior (1439–44) while Fra Angelico painted. He attended the Council of Florence (1439–45) and became archbishop in 1446. He died at Montughi, Florence, on May 2, 1459, much beloved for his charity. His principal work is the *Summa moralis*. He was canonized in 1523, and his feast day is May 10.

See the standard biography, R. Morçay, *S. Antonin* (1914); B. Jarrett, *St. Antonino and Mediaeval Economics* (1914). (S. BH.)

ANTONINUS PIUS (TITUS AURELIUS FULVUS BOIONIUS ARRIUS ANTONINUS) (A.D. 86–161), Roman emperor A.D. 138–161, was born on Sept. 19, A.D. 86. He was grandson on the father's side of Aurelius Fulvus (twice consul, and urban prefect), on the mother's side of Arrius Antoninus (also twice consul); his wife was a daughter of Annius Verus (three times consul). By further ties he was linked to most of the new governing class of Rome, the nobility who had been brought to the fore by the Flavian emperors. Antoninus had a distinguished public career: he was consul in 120, and later one of the former consuls charged by Hadrian with judicial administration in Italy; he governed the province of Asia, and after his governorship he was a frequent adviser of the emperor. In view of this it is surprising that he was not Hadrian's first choice as successor to the principate. Only in 138, *faute de mieux*, was he adopted by Hadrian and indicated as successor, and then only as a place-warmer for the youths Annius Verus and Ceionius Commodus (the future emperors Marcus Aurelius and Lucius Verus respectively), whom he in his turn adopted. Shortly afterward Hadrian died and Antoninus became emperor. He persuaded a reluctant senate to offer the usual divine honours to his predecessor, though it is probably not solely for this dutiful act that he received the name Pius.

Though the literary authorities for Antoninus' principate are exceptionally scanty, it need not be doubted that few striking events happened. Tendencies of a general kind were at work, especially the growth of bureaucracy and the decline of local initiative in the provinces. In the first decade of Antoninus' reign there was a major rebellion in north Britain. Hadrian's wall had proved inadequate, and in 141 the situation was serious. The revolt was overcome by Lollius Urbicus, the governor, who then built the turf wall known as the Antonine wall (*q.v.*) between the Firths of Clyde and Forth. In the second decade there was more trouble in Mauretania, Germany, Dacia and Egypt; but the barbarian invasions had not yet begun, and the standing army was still adequate to its tasks. Parthia was kept at peace by negotiation, as in Hadrian's time. When Antoninus' wife Faustina died in 140, she received divine honours, and an institution for bringing up the daughters of poor citizens, the *puellae Faustinianae*, was founded to her memory.

Unlike Hadrian, Antoninus did not travel. He stayed in Rome and governed with the advice of those best qualified to give it. His personal contribution to Rome's development was not negligible—it consisted of a wide-ranging program of legislation, not original in conception but covering the whole field of law, softening its harshness and removing its anomalies. Antoninus was a careful financial administrator and left the treasury in a sound

condition in spite of lavish largesses to the Roman plebs. In 143 or 144 the orator Aelius Aristides delivered his panegyric on Rome, a notable tribute to the blessings of the Roman peace, and in 147 Rome celebrated the 900th anniversary of its traditional foundation. Antoninus died peacefully on March 7, 161, at Lorium just outside Rome, after giving to the tribune of the watch for the day the password *aequanimitas* ("peace of mind"). He was later accorded divine honours.

ANTONIO, DOM (1531–1595), generally known as the PRIOR OF CRATO, claimant of the throne of Portugal, was the illegitimate son of Luis, duke of Beja, brother of John III of Portugal. He became head of the Order of St. John in Portugal and was endowed with the wealthy priory of Crato (1555). He accompanied John III's grandson and successor Sebastian to North Africa, where in the battle of the Three Kings near Alcazarquivir (1578) Sebastian was killed and Antonio captured. On his return to Portugal, his claim to be heir presumptive was not supported by Sebastian's successor Henry, the last surviving brother of John III (*see* PORTUGAL: *History*), nor by the council which governed Portugal for some months after Henry's death (Jan. 1580). Antonio was acclaimed king by his supporters in June 1580, but his possession of the crown was contested by Philip II of Spain whose army, under the duque de Alba, defeated Antonio outside Lisbon in August.

Antonio then went to Paris. With French help he sent naval expeditions to the Azores, where he was still recognized as king, in 1582 and 1583, but they were defeated by Spanish squadrons. He next went to England where he enlisted the help of Elizabeth I. An English fleet effected a landing near Lisbon in support of Antonio in 1589, but the expedition proved a costly failure. Impoverished and in ill-health, Antonio returned to Paris, where he continued to make plans for further expeditions until his death on Aug. 26, 1595. (DA. A. P.)

ANTONIO, NICOLÁS (1617–1684), bibliographer and first systematic historian of Spanish literature, was born in Seville on July 28 or 31, 1617, and died in Madrid on April 13, 1684. His *Bibliotheca Hispana*, in two parts (*Nova*, 1672; *Vetus*, 1696), a vast Latin bibliographical index of Peninsular and Spanish colonial writers after 1500, with critical evaluations, followed by a history of Peninsular literature from the reign of Augustus to 1500, marks the emergence of modern bibliography and the transformation of literary history from a branch of belles-lettres into a scholarly discipline. The division of the work at 1500 anticipates the establishment of the *terminus ad quem* for incunabula (*q.v.*). A second edition (1788; vol. i of the *Nova* wrongly dated 1783), with important additions from Antonio's manuscripts, is regularly consulted by scholars. The manuscript of the unpublished *Bibliotheca Hispano-rabbinica* is in the National library in Madrid. In his *Censura de historias fabulosas* (1742), Antonio applied his special skills to discrediting certain celebrated historical forgeries. (F. S. R.)

ANTONIUS, the name of an old plebeian family in ancient Rome.

MARCUS ANTONIUS (143–87 B.C.), a great orator, vividly portrayed as a speaker in Cicero's *De Oratore*. None of his speeches survives. Consul in 99 and censor in 97, he was a confirmed member of the *optimates* (families owing their prestige to wealth and repeated tenure of office in successive generations) and perished in the reign of terror that followed the capture of Rome by Marius and Cinna in 87.

MARCUS ANTONIUS, derisively surnamed CRETICUS (d. *c.* 72 B.C.), elder son of the first-mentioned Marcus Antonius. Praetor in 74 B.C. and an inept naval commander, he was defeated in battle by the Cretan pirates in 72 and died soon after.

GAIUS ANTONIUS, derisively surnamed HYBRIDA (d. after 42 B.C.), younger son of the first-mentioned. Though expelled from the senate by the censors of 70 B.C., he was elected with Cicero to be consul in 63 and commanded an army in Etruria against Catiline, with whom he was thought by Cicero to be not unsympathetic. On his return to Rome after governing Macedonia he was prosecuted for extortion in 59, defended by Cicero, but condemned. He was later recalled from exile by Caesar, and was censor in 42.

GAIUS ANTONIUS (d. 42 B.C.), second son of Marcus Antonius Creticus, was *legatus* of Caesar in 49. In 43 he was captured in Apollonia by M. Junius Brutus, who had him executed in 42.

LUCIUS ANTONIUS (d. after 40 B.C.), third son of Marcus Antonius Creticus, quaestor in Asia 50 B.C., tribune in 44 and consul in 41. He was defeated by Octavian in the Perusine War (41–40 B.C.).

MARCUS ANTONIUS (*c.* 82–30 B.C.), Mark Antony, eldest son of Marcus Antonius Creticus, was, with Cleopatra, the queen of Egypt, defeated by Octavian (later the emperor Augustus) in 31 B.C. in the last of the civil wars that destroyed the Roman republic. Much that is unfavourable in the historical tradition about him must be discounted as based on intemperate abuse by Cicero (*q.v.*) and on Octavian's propaganda during the war and his patronage of historical writing after it.

Antony was on Caesar's staff in Gaul from 54 (in 52, as quaestor) and in 50 was elected augur and tribune for 49. He was one of the two obstructive tribunes who, after warning from the consuls, fled to Caesar on Jan. 7, 49. Left in charge of Italy as propraetor in 49, he brought troops across to Caesar in Illyricum that winter and commanded the left wing at Pharsalus in 48. He was master of the horse to Caesar as dictator in 48/47 but not after 46, when he and Caesar quarreled. In 44, when they were joint consuls, they were again at variance.

He was detained at the door of the senate house when Caesar was murdered on March 15, 44, and Cicero never tired of saying that he should have been murdered too. In the hours and days that followed he controlled events with brilliant skill, securing Caesar's papers from his widow, taking possession of the treasure left by Caesar, preventing M. Aemilius Lepidus from bringing in his troops to attack Caesar's assassins on the capitol and, as presiding consul, engineering the compromise by which on March 17 the senate granted an amnesty to the assassins and at the same time confirmed Caesar's acts. His funeral oration over Caesar's body, probably on March 20, following the publication of Caesar's will, won him immense popularity with the Roman populace, and he acquired a dangerous power when the senate made him sole judge of the authenticity of alleged "acts" of Caesar.

The return to Italy at the age of 18 of young Octavian, Caesar's great-nephew, whom he had adopted in his will and named as heir to his property, was a warning, for Octavian inherited the loyalty of Caesar's troops and astutely ingratiated himself with the senate. On June 2 by a popular bill Antony secured the government of Cisalpine and Transalpine Gaul for five years, with the legions then in Macedonia. With two of the four legions brought across to Brundisium that were loyal to him, he moved north to evict Decimus Junius Brutus, one of the assassins, from Cisalpine Gaul. On April 14, 43, he was defeated at the battle of Forum Gallorum by a Roman army that had come to Brutus' relief, commanded by the two consuls, with Octavian in subordinate command. Antony escaped across the Alps, where the three proconsuls Gaius Asinius Pollio, Lepidus and Lucius Munatius Plancus, with their armies, joined him, and in late October Octavian, then consul, met him at Bononia (Bologna) and the triumvirate of Antony, Lepidus and Octavian was formed. It was later regularized by a law (the *lex Titia*) at Rome.

The triumvirs were granted military command and provinces for five years. The proscriptions, of which Cicero was a victim, followed, as did in 42 the defeat of Brutus and Cassius (*qq.v.*) at Philippi, the whole credit for the victory resting with Antony. Octavian returned to Italy to supervise the demobilization of troops; to fight an army commanded by Antony's third wife, Fulvia, daughter of M. Fulvius Bambalio and his brother Lucius

(the Perusine War); and to face a corn shortage at Rome occasioned by the piracy of Sextus Pompeius. Antony remained to settle problems in the east, summoned Cleopatra to Tarsus in 41, fell in love with her and lived with her through the winter in Alexandria. The Parthians then invaded Roman territory.

Threatening rifts were closed when Antony returned to Italy and met Octavian in 40 at Brundisium, where he received command of the eastern provinces of the empire and, Fulvia having died, married Octavian's sister Octavia; in 39 at Misenum, where a short-lived agreement was made with Sextus Pompeius; and in 37 at Tarentum, where the triumvirate was renewed to the end of 33, and Antony promised Octavian 130 ships for use against Sextus Pompeius in exchange for four legions (which were never sent) for the Parthian war. Antony's treatment of Octavia could not easily be tolerated by Octavian, for in late 37 or early 36 Antony married Cleopatra (though, as she was not a Roman, it was not valid in Roman law) and in 35 he severed relations with Octavia. Antony's campaign against Parthia in 36 ended in disaster, though he conquered Armenia in 34 and celebrated a Roman triumph in Alexandria, which was the occasion of extravagant honours and territorial gifts to Cleopatra and her children. Reports of his unrestrained assumption in public of the character of a Hellenistic divine king were seized on avidly by Octavian for skilful propaganda in Italy. None the less, Antony was joined in 32 by the two consuls and by numerous senators from Rome. In Rome Octavian secured and published, whether it was genuine or forged, Antony's will, in favour of Cleopatra and his children by her.

Antony's mobilization of a fleet started in winter 33–32. He was now financed and politically impelled by Cleopatra, yet aware that his Roman officers and troops wanted him to break with her. After his defeat at Actium (*q.v.*) in 31 by Octavian he fled with Cleopatra to Alexandria and there, after Octavian's arrival, on the false news of Cleopatra's death he committed suicide on Aug. 1, 30 B.C. (*See* also AUGUSTUS.)

Antony was personally attractive, a good soldier, capable of brilliant political improvisation, but incapable of the cold far-sighted scheming by which Octavian outmaneuvered him. Before his marriage to Fulvia he was married first to Fadia and second to Antonia, daughter of Gaius Antonius Hybrida. His elder son by Fulvia, Marcus Antonius Antyllus, was put to death by Octavian in 30; his younger son by Fulvia, Iullus Antonius, married to Octavian's niece and consul in 10 B.C., was forced to suicide in 2 B.C.; through his two daughters by Octavia, Antonia *maior* and Antonia *minor*, married to Lucius Domitius Ahenobarbus and Nero Claudius Drusus (*qq.v.*) respectively, the emperors Gaius, Claudius and Nero were his descendants. By Cleopatra he had two sons and a daughter. His love for her inspired Shakespeare's *Antony and Cleopatra* and Dryden's *All for Love.*

Rice Holmes, *The Roman Republic and the Founder of the Empire,* vol. iii (1923); *The Architect of the Roman Empire,* vol. i (1928); H. Frisch, *Cicero's Fight for the Republic* (1946); R. Syme, *The Roman Revolution,* 2nd ed. (1951). (J. P. V. D. B.)

ANTONOMASIA, in rhetoric the Greek term for a substitution of any epithet or phrase for a proper name, such as the "Maiden Queen" for Queen Elizabeth I, and in sports, the "Great Bambino" for Babe Ruth, "Galloping Ghost" for Red Grange; or a proper name to describe a typical characteristic, such as "Solomon" for any wise man. *See* FIGURES OF SPEECH: *Figures of Relationship.* (G. W. A.)

ANTONY, MARK: *see* ANTONIUS.

ANTRIM, RANDAL MacDONNELL, 1ST MARQUESS OF (1609–1683), Irish royalist, played a minor part in politics during the English Civil War and is remembered chiefly for abandoning the king's cause in 1647. He was born on June 9, 1609, the son of the 1st earl of Antrim, and educated as a Roman Catholic. In 1635 he married Katherine, widow of George Villiers, 1st duke of Buckingham. On the outbreak of the Bishops' Wars in 1639, he planned an attack on Argyll in Scotland, which came to nothing. From that time onward he was engaged in various schemes for the assistance of Charles I against parliament—all of them abortive. He was at various times arrested as a suspect. The papers found on him at his capture in 1643 informed the parliamentary leaders of a plan for a rising by the earl of Montrose in Scotland to be supported from Ireland. On Jan. 26, 1644, MacDonnell was created a marquess on Montrose's recommendation. He was employed on various missions in Ireland and on the continent until 1647, when he ceased to support the king's cause. Annoyed when the marquess of Ormonde was reappointed lord lieutenant, he entered into communication (1649) with Cromwell, for whom he performed various services, though there appears no authority to support the story that Antrim was the author of a forged agreement for the betrayal of the king's army by Lord Inchiquin. Subsequently he joined Henry Ireton and was present at the siege of Carlow. He returned to England in Dec. 1650, and in lieu of his confiscated estate received a pension of £500, later increased to £800, together with lands in Mayo. At the Restoration, Antrim was excluded from the Act of Oblivion because of his religion and, on presenting himself at court, was imprisoned in the Tower of London, subsequently being called before the lords justices in Ireland. In 1663 through the influence of the queen mother he obtained a pardon, his estates being restored to him by a proviso in the Irish Act of Explanation in 1665. Antrim died at Ballymagarry, County Antrim, on Feb. 3, 1683. He is described by Clarendon as of handsome appearance but "of excessive pride and vanity and of a marvellous weak and narrow understanding."

ANTRIM, a county of Northern Ireland, occupies the northeastern corner of Ireland, being separated from the Mull of Kintyre in Scotland, less than 13 mi. away, by the North channel. It is bounded north and east by the Atlantic ocean and the Irish sea, south by Belfast lough and the river Lagan, dividing it from the counties of Down and Armagh, and west by Lough Neagh and the lower river Bann, separating it from the counties of Tyrone and Londonderry. The land area is 1,098 sq.mi.

Physical Features.—The northern and eastern part of the county is occupied by a Tertiary basalt plateau which is cut by deep glens. Glens and hills follow the same trend, northeast-southwest, as the mountains of Scotland. The Antrim plateau ends at its northeastern corner in Fair head (626 ft.), a perpendicular cliff. Much of the plateau consists of rolling moorlands and peat bogs. The collapse of the basalt at its southwestern corner caused the depression which is occupied by Lough Neagh (*q.v.*), the largest inland lake in the British Isles. There are also some outstanding peaks of older or of intrusive rock. Mountains include Trostan (1,817 ft.), Knocklayd (1,687 ft.), Slieveanorra (1,676 ft.) and Slemish (1,437 ft.). Of the Belfast hills, south of the main Antrim plateau, the highest is Divis (1,560 ft.).

The basalt reaches the sea along the north coast in steep cliffs. At the Giant's Causeway (*q.v.*) it makes a curious formation of perpendicular columns, mostly six-sided. A narrow zone of Jurassic, Triassic and Cretaceous rocks separates the basalt from the east coast. Triassic and Cretaceous rocks also bound the basalt on the southeast, and Triassic sandstone is extensive in the Lagan valley. (HU. S.)

History.—It seems that man first came to Ireland through Antrim from Scotland. There are many traces of early life, particularly in the Lough Neagh district where quantities of flint implements have been discovered, thought to date from about 6000 B.C. The county abounds in cromlechs and other monuments and there are also remains of ancient man in the form of kitchen midden deposits in the sand dunes of White Park bay.

St. Patrick is depicted as a swineherd in the county coat of arms, for it was on the western slopes of the mountain of Slemish, near Ballymena, that the national saint is reputed to have tended swine when brought as a boy prisoner to Ireland following an Irish raid on the coast of Great Britain. There have been many invasions and counterinvasions between Antrim and Scotland. The original "Scots" came from Ulster. Early in the 6th century there was a migration of Scots from the Ulster kingdom of Dal-

riada (*q.v.*) in northeastern Antrim over to Scotland, so that Dalriada came to lie on both sides of the North channel, its eastern portion, known as Argyll, developing later into the nucleus of the kingdom of Scotland.

Scandinavian invaders came up the Bann into Lough Neagh, but made no permanent settlements. Antrim was partially penetrated by Anglo-Norman adventurers from the 12th century and formed part of the earldom of Ulster. The disorders of the later middle ages and the invasion of Edward Bruce from Scotland in 1315 brought about the decline of the English power, and the only settlement which remained in Tudor times was the town and fortress of Carrickfergus. During Tudor times a number of adventurers attempted with varying success to colonize Antrim and many Scots settled there. Among towns founded then was Belfast. Although Antrim was not part of the territory involved in the scheme for the plantation of Ulster, it continued to attract many immigrants from Britain.

The Presbyterian Church predominates in the county. In 1861 Presbyterians represented 53% of the total population and the figure was still as high as 45% in 1951. It was no doubt because of this strong Presbyterian influence that Antrim men played such a leading part in the rebellion of 1798. The hill country from Cavehill to the ancient town of Antrim was a training ground for the rebels, whose leader Henry Joy McCracken was tried and publicly executed in Belfast. In an earlier campaign, carried out by William III against James II, County Antrim had also had its place, for William landed at Carrickfergus and traveled from there to the battle of the Boyne (1690).

Population and Administration.—In 1961 the population of the county was 273,905. At one time Carrickfergus was the county town but with the Industrial Revolution the small town of Belfast began to expand rapidly and in 1847 a new county courthouse was built in Belfast and the grand jury moved from Carrickfergus. However, Belfast became a county borough in 1898 and, while the county courthouse remains legally in County Antrim, the county lacks a county town.

House building round the northern boundaries of Belfast increased rapidly after World War II and one result of this was the establishment in 1958 of a new urban district, Newtownabbey (*q.v.*). The population of Newtownabbey (37,448) makes it by far the largest town in the county. The next in order of size are Lisburn (17,700), Larne (16,350), Ballymena (14,734) and Carrickfergus (10,211) (*qq.v.*).

County Antrim returns seven members to the parliament of Northern Ireland and two members to the United Kingdom parliament.

Agriculture, Industry and Communications.—Agriculturally Antrim is a rich county. Oats, potatoes and seed hay are the chief crops. There is extensive beef production together with sheep farming, poultry and pig rearing. The land in the valley of the Six-Mile-Water, particularly around Ballyclare, is probably among the richest in Northern Ireland, and other important agricultural districts are centred around Ballymena and Ballymoney. There is considerable salmon fishing off the north coast and the eel fisheries on the river Bann are of some importance.

The county is not particularly rich in minerals, but coal is still mined in small quantities around Ballycastle. There were at one time bauxite mines in the Parkmore district and salt used to be mined on a considerable scale at Carrickfergus.

The government is building factories at Newtownabbey, but the main industrial town is Larne which has a large turbine factory, a radio factory and a sizable port. Nearby, cement is produced on a large scale at Magheramorne. Ballymena has a fair-sized linen industry as well as some light engineering works, while Carrickfergus has a large textile factory. Lisburn is noted for its furniture and linen industries, the latter having been established by Huguenot refugees from France in the 17th century.

With its long coastline and excellent beaches County Antrim has an extensive tourist trade. Two fine beaches at White Park bay on the north coast and Cushendun on the east coast are owned by the National Trust, while the county council is carrying out tourist development schemes at several places to preserve the natural beauty. The towns of Portrush, Ballycastle (*qq.v.*) and Whitehead and the villages of Portballintrae, Cushendun and Cushendall are noted holiday resorts, all on or near the coast.

There is a direct passenger-steamer service between Larne and Stranraer, Scot., while Belfast airport at Nutts Corner in County Antrim is the civil airport for Northern Ireland. The main railway line from Belfast to Londonderry runs through the length of County Antrim and the main line from Belfast to Dublin runs through its southern part. Several branch lines of former importance were closed, but there are adequate bus services throughout. Two motorway approaches to Belfast were constructed in the early 1960s, one from the north and the other from the south. There is also one of the finest systems of trunk and other roads to be found in Ireland. It was the building of the coast road in the first half of the 19th century which opened up the glens in the northeastern corner of the county; before that time they were relatively inaccessible and backward. In the 1960s Irish was still spoken in some parts. (W. J. Jo.)

Bibliography.—John Dubourdieu, *Statistical Survey of County Antrim* (1812); George Hill, *An Historical Account of the MacDonnells of Antrim* (1873); E. R. R. Green, *The Lagan Valley, 1800–50* (1949); G. Camblin, *The Town in Ulster* (1951).

ANTRIM, a town of County Antrim, N. Ire., lies in the valley of the Six-Mile-Water rivulet at the northeastern corner of Lough Neagh, 17 mi. N.W. of Belfast by road. Pop. (1961) 1,448. Area 0.3 sq.mi. Antrim is an important road junction and much traffic passes through it between Belfast and the towns of northern and northwestern Ulster. As a market town it serves a populous countryside and it is the site of several small industries, including sawmilling and the production of linen and woolen goods. There are naval and air force establishments in the district. Less than 1 mi. N. of the town is one of the most perfect of the round towers of Ireland. Dating from the 10th century or earlier, it is 93 ft. high and about 17 ft. in diameter at the base. Antrim castle, built in the 17th century, also testifies to the strategic advantage which the site had in earlier times. In 1798 the town was the scene of a battle in which several thousand insurgents, led by Henry Joy McCracken, were defeated by the military. (Hu. S.)

ANTRUSTION, the general name for a member of the personal guard of the Merovingian sovereigns in France. The free man who wished to enter the royal guard presented himself, armed, before the king, swore the *trustis* (a special oath of fealty) to him and engaged himself to defend him. In return he enjoyed the king's special protection, could only be tried in a royal tribunal and had a wergild ("man-price" paid for homicide) three times that of the ordinary Frank. The king employed him on confidential missions and might reward him with grants of land to be held outright. The antrustions formed a body whose members had mutual obligations; they were not able to give evidence against one another, and litigation between them was governed by intricate formalities. They seem to have been the only permanent military force under the Merovingians.

The antrustions were the successors of the body of "companions" of the Germanic chieftains described by Tacitus—an institution appropriated to himself by the Merovingian king in the 6th century. They were of great importance under Clovis, but with the accelerating decay of royal power in the 7th and 8th centuries they declined. At the beginning of the reign of Charlemagne they were of no importance and they disappeared entirely on the rise of a new institution, vassalage.

Bloch, *La Société féodale. La formation des liens de dépendance* (1939); F. Lot, *Naissance de la France* (1948); A. Bergengruen, *Adel und Grundherrschaft im Merowingerreich* (1958). (Je. H.)

ANT THRUSH, the name given to a large group of small and medium-sized passerine birds comprising the family Formicariidae and occurring in the American tropics. The name is in reference to their habit of accompanying ant armies to prey on insects flushed by the ants. Most of the 222 recognized species have loose-webbed plumage that is predominantly black, gray or brown. The colours may be solid, barred or streaked; the sexes

usually differ in colour. Many species are crested, and in most the feathers of the lower back are notably long and dense, with a concealed white or rufous patch. The bill is strong and hooked. Ant thrushes, which also are known as ant birds, ant shrikes and bush birds, inhabit forests or brushlands and may be either arboreal or essentially terrestrial. They are weak fliers and do not migrate. They utter harsh calls, whistling notes and occasionally melodious songs. (E. R. BE.)

ANTUNG (AN-TUNG), a Chinese city near the mouth of the Yalu river in the southeastern part of Liaoning province (39° 59′ N., 124° 30′ E.). Pop. 360,000 (1953). It was opened as a treaty port in 1907 and developed into an important centre of trade between China and Korea. The harbour accommodates ships with a draft of about 9 ft. Its staple export items include soybean oil, soybeans, timber, and light industrial products such as matches, flour and wild cocoon silk. The port is icebound four months in a year.

Antung increased its importance after the construction of a railway in 1907 linking Mukden (Shen-yang) with Korea; the railway spans a half-mile-long bridge over the Yalu between Antung and the Korean city of Hsinyichou (Sinuiju). A number of modern industries have sprung up at Antung. These include a chemical fibre plant, completed in April 1958, with an annual capacity of 400 tons; flour and soybean mills; an aluminum plant; and paper factories. Power is supplied by the Shuifeng hydroelectric station, upstream on the Yalu river, which has a total capacity of over 600,000 kw. Antung also has an airport on the Dairen-Antung-Mukden air route.

Between 1932 and 1945, Manchuria was divided under the puppet Manchoukuo regime into many provinces of which Antung was one. The census of Oct. 1, 1940, described Antung province as consisting of six counties and one municipality with a total population of 1,170,787 (including 182,283 for Antung city). (KN. C.)

ANTWERP (Flem. ANTWERPEN; Fr. ANVERS), the most northerly of the nine provinces of Belgium, adjoins the Dutch frontier. After the French occupation of 1795, it was made part of the French *département* of Deux-Nèthes, and in 1815 its present boundaries were established, though subsequently modified in detail. The province is divided into three *arrondissements* (Antwerp, Malines and Turnhout), subdivided into 19 cantons and 151 communes. Area 1,104 sq.mi. Pop. (1961) 1,443,355.

Most of the area is covered with Pliocene sands and gravels, with a smaller extent of Miocene and Oligocene deposits in the southwest. Superficial sheets of sand overlie much of the centre and east, forming part of the Kempen heathlands. Much of this exceeds 75 ft. in altitude forming a tongue of low plateau projecting westward, from which rise gently swelling eminences (*bergen*) to about 115 ft. In the southwest, near Herentals, an outcrop of soft Lower Pliocene (*Diestian*) sandstone forms a more diversified relief than the sands and gravels, because of its resistance to erosion; a line of hills, culminating in the Langenberg (131 ft.), extends from northeast to southwest near the valley of the Kleine-Nethe. Other hills occur farther south; Heist-op-den-Berg rises from an eminence at 148 ft. The land slopes away gently northward into the Netherlands and westward into the clay-covered polderlands of the Scheldt estuary. Numerous streams (notably the Mark) flow northward to the Maas (Meuse); to the south drainage is by the many headstreams of the Nethe; the watershed is very indeterminate.

The heathland is characterized by areas of sand dunes, with marshy depressions containing small lakes, areas of ling and broom, and poor pasture. There are extensive blocks of coniferous plantations. The landscape changes gradually westward toward the Scheldt; there is progressively less heathland, more market gardening and dairy farming and more numerous villages and small towns. Much of the polderland along the Scheldt is intensively farmed to supply the demands of the city of Antwerp.

Apart from Antwerp (*q.v.*), the chief town is Malines (in Flemish Mechelen; *q.v.*), situated on the banks of the tidal Dyle. It is a market centre for the surrounding agricultural land and has a wide range of industries: furniture, textiles, clothing, lace, paper, leather and food processing. Turnhout (*q.v.*) is a prosperous market, industrial and administrative town in the north of the province, and a centre of road, rail and canal communications. Its industries are varied: the making of paper, stationery, playing cards, sacking and canvas, cigars, pottery, leather and lace. Around the canal basin in the northwest are timber yards, sawmills, cement works and flour mills, and 29 brickyards are along the canal banks. Mol is on the railway from Antwerp, and makes cigars, leather, pottery, textiles, clothing and blankets. Herentals has similar small-scale industries, including also the manufacture of copper and bronze articles, and a large factory makes industrial explosives and cartridges. Several large factories are located in the heathlands; including the Mol-Gompel glass works, two zinc refineries, and a huge refinery at Oolen (2 mi. E. of Herentals) which produces radium, uranium, cobalt, copper and arsenic. Baarle-Hertog (Fr. Baerle-Duc) is a small Belgian enclave in the Netherlands, the Dutch part being called Baarle-Nassau. The frontier is so confusing that neighbouring houses, or even parts of the same house, may find themselves on different sides of it. Apart from the towns, the heathlands are thinly inhabited. Villages are situated at road junctions, at rail-canal intersections, and on low eminences away from the marshes.

The heathlands were for long poorly served with communications. A mainline railway runs from Brussels via Mechelen and Antwerp into the Netherlands; another line runs southeast from Antwerp via Lier and Hasselt; and a third east from Lier across the centre of the heathland via Herentals-Geel-Mol into the Netherlands. A north-south line from the Netherlands passes through Turnhout and Herentals. There is a considerable mileage of light railway (tramway) serving the small towns and villages; six lines focus upon Oostmalle to the northeast of Antwerp and five lines upon Turnhout. A small waterway (Desschel-Turnhout-Schoten canal) curves around the northern part of the province, but much more important is the Albert canal which crosses the southern part on its way from Antwerp to Liège. (F. J. M.)

ANTWERP (Flem. ANTWERPEN; Fr. ANVERS), capital of the province of the same name, the second largest town in Belgium and chief port and commercial centre of the country, lies on the Scheldt (*q.v.*) (Flem. Schelde) in the centre of a vast alluvial plain about 55 mi. from the North sea.

Pop. (1961) 253,295.

Antwerp is situated on both banks of the river, the city proper being on the east bank. There are no bridges, but after 1933 the banks were connected by tunnels—one for pedestrians and one for vehicles. The oldest part of the city extends from the river to a line of broad avenues, which were laid out on the site of the 16th-century ramparts when these were demolished in 1859. The walls built around the city in the 13th century have completely disappeared. The town was extended, chiefly toward the north, and large public gardens were laid out. The most striking building is the Cathedral of the Holy Virgin, begun in the 14th century and not completed until nearly 200 years later; a thorough restoration was carried out in the 19th and 20th centuries. It is the biggest church and one of the finest Gothic buildings in the country, and has a tower more than 400 ft. high; a second tower, begun in the 15th century, was never finished. The cathedral contains, among other paintings, three of Rubens' masterpieces, "The Descent from the Cross," "The Elevation of the Cross," and "The Assumption" (above the high altar). St. James's church, in flamboyant Gothic style, was founded in 1491 but not finished until 1656. The Rubens chapel contains the tomb of the artist whose "Virgin and Child With Saints" is the altarpiece. St. Paul's, a 16th-century Dominican church (with a bell tower dating from the 17th century), and St. Augustine's both possess works by Rubens, Van Dyck, Jordaens, P. Verbruggen and other artists. The former Jesuit church of St. Charles Borromeo, originally dating from 1615–21 but partly rebuilt in the 18th and 19th centuries after destruction by fire, has a splendid baroque façade and contains a small museum of old lace.

The early medieval town grew up around a fortress called the Steen which lies on the river bank. The present castle, whose stone foundations are of the 9th century, dates largely from 1520 but

FOTOWERKEN FRANS CLAES, COPYRIGHT S A B A M—BRUSSELS

CATHEDRAL OF THE HOLY VIRGIN, ANTWERP: BEGUN IN 14TH CENTURY

was greatly restored in 1889 and now houses the national maritime museum. Nearby is the *stadhuis* or townhall (1561–65), a Renaissance structure combining both northern and Italianate elements in its architecture and with frescoes by H. Leys, a native artist. It stands in the Grote Markt (market square) which also contains the Brabo fountain and typical Renaissance buildings. The Meir, a short wide road running west-east, is now the centre of the city, with big shops, banks and offices, and also the royal palace. In the Rubens Straat, off the Meir, is the house which the famous painter built and in which he lived from 1615 until his death in 1640. Once almost demolished, it has now been carefully restored. The Bourse or Exchange (1531) was destroyed by fire in 1858 and rebuilt in 1872. Fire has also destroyed several other old buildings in the city, notably in 1891 the house of the Hanseatic league near the northern quays.

Of several museums the Plantin-Moretus and the Fine Arts museum are the most important. The former, to the southwest of the cathedral, is the old Plantin house, the home of the great 16th-century printer (*see* PLANTIN, CHRISTOPHE) and of his successors, the Moretus family. In it, the pressroom, foundry, proofreaders' room and bookshop are still in their original state. The house also contains an exceptional collection of manuscripts, books, woodblocks, copper plates, etc., as well as paintings by Rubens and others, tapestries and furniture. The Royal Museum of Fine Arts (1880–90), to the south, has a superb collection of paintings by the great masters of the Flemish and Dutch schools, and also 15th-century Flemish primitives and many modern European works. In 1950 the Museum Knight Smidt van Gelder was opened; it is a richly furnished 18th-century patrician's house. The old Butchers hall (*c.* 1500) is a museum of arts and crafts, archaeology and history. The Mayer van den Bergh museum possesses masterpieces of the Flemish school, old embroidery, lace, sculptures and ivories. There are a Royal Opera house and a Royal theatre. Antwerp has several large parks, a botanical garden and a well-known zoological garden, with a natural history museum and aquarium, near the central station. In the grounds of the former château of Middelheim adjacent to Nachtegalen park is an open air museum where, in odd-numbered years, a biennial international exhibition of sculpture is held.

Antwerp's educational institutes include schools of engineering, navigation and diamond working, commercial and colonial universities, a music academy, institutes of fine arts and of architecture and a university foundation for tropical medicine.

Commerce.—Antwerp has three railway stations and is connected directly by rail to Paris, Amsterdam, Brussels and Basel. There is an international airport at Deurne, 3 mi. S.E. of the city. The Albert canal links Antwerp with Liège. The port began its rapid growth after 1863 when Dutch rights to levy toll were redeemed by purchase. It is the greatest Belgian port and one of the four biggest European ports. It consists of two parts: a roadstead, or outer harbour, facing the city, and an inner harbour with extensive installations, lying to the north of the city. There are 19 maritime docks, 10 municipal dry docks and 6 private dry docks. The harbour is connected with the Scheldt by means of six locks, the most recent and largest being the Baudouin lock with a length of 1,180 ft., a width of 147 ft. and a depth at average high tide of more than 50 ft. Because of a vast expansion program, a large territory, including three rural villages north of the city, was in the late 1950s incorporated in the port's area, increasing the total area from 3,460 ac. to 13,200 ac., including the water area of 1,325 ac. which reached more than 2,000 ac. by the 1960s. The total berthage space was increased to 50 mi. More than 16,000 seagoing ships of above 34,000,000 net register tons enter Antwerp yearly, discharging an average 20,000,000 tons of cargo and loading about 15,000,000 tons. Antwerp is not merely of importance for Belgian imports and exports but also has a considerable transit traffic, chiefly to and from the German Federal Republic, especially the Ruhr area. Established in the harbour area are shipyards, sawmills, scrap-iron plants, assembly plants for U.S. automobiles, and oil refineries. Other industries in Antwerp include food and chemical industries. Rubber, ivory and radium are imported from the Congo and marketed at Antwerp. The most important local industry, established in the 16th century, is diamond cutting.

History.—Legend has it that the name Antwerp was derived from *hand werpen* ("to throw the hand"), based on the mythological Roman giant, Druon Antigonus, who supposedly cut off the hands of those mariners who sailed past his castle without paying tolls and threw them in the Scheldt. Another derivation is from the name given to the first settlement *Aen de Werpen* ("at the wharfs"). In the 11th century, when the city was first walled, Antwerp was a marquisate, for some years under the famous Godfrey of Bouillon (*q.v.*). It was the headquarters of Edward III during his early negotiations with Jacob van Artevelde, and his son Lionel, duke of Clarence, was born there in 1338. After the death of Duke John III (1355), Antwerp, which had been under the authority of the dukes of Brabant since the 13th century, came under the domination of the count of Flanders and later of the dukes of Burgundy. Toward the end of the 15th century, with the silting up of the Zwyn and the consequent decline of Bruges, and the enlargement of the western Scheldt by floods, the foreign trading guilds and banks (the first real *bourse* in Europe was founded in Antwerp in 1460) were transferred from Bruges to Antwerp, and the latter became the chief port and commercial centre of the Netherlands and of western Europe. At the beginning of the 16th century there were at least 1,000 foreign business houses established in the city and by 1560, the highest point of its prosperity, Antwerp had superseded Venice in its first place in European commerce.

It was not only in trade that Antwerp had become great, but also in the arts. It had taken the place of Bruges as the centre of Flemish art and its school of painting, of which Quentin Massys (*q.v.*) was a founder, exercised a far-reaching influence. Van Dyck, David Teniers, A. Brouwer, F. Snyders and J. Jordaens were all natives or citizens of Antwerp and members of its guild of painting, and Rubens lived and died there. Pieter Bruegel was another great member of the Antwerp school.

The religious troubles that marked the second half of the 16th century broke out in Antwerp as in every other part of what is now Belgium excepting Liège. In 1576, following upon disturbances, the Spanish garrison plundered the town during what was called "the Spanish Fury," and thousands of citizens were massacred and many houses destroyed. In the following year,

having thrown off the Spanish oppressors, the people destroyed the citadel, and Antwerp came under Calvinist rule. In 1585, after a long siege, Antwerp was recaptured by the Spanish and its Protestant citizens sent into exile. Under Albert and Isabella, who made their state entry into Antwerp in 1599, the city experienced a period of peace and splendour. The recognition of the independence of the United Provinces by the treaty of Münster in 1648 carried with it a severe blow for Antwerp, for it stipulated that the Scheldt should be closed to navigation. The city's prosperity had already begun to decline, and its port was now ruined. In 1795, under French rule, the provisions of the treaty were relaxed, and the Scheldt was reopened to shipping. The port began to develop again rapidly when Napoleon built docks and a naval arsenal in order to make Antwerp the chief military harbour in his empire. In 1830 the city was captured by the Belgian insurgents, but the citadel continued to be held by a Dutch garrison under Gen. David Chassé. For a time this officer subjected the town to a periodical bombardment which inflicted much damage, and at the end of 1832 the citadel itself was besieged by a French army under Maréchal Etienne Gérard until, after a gallant defense, Chassé made an honourable surrender.

At the end of the 19th century Antwerp was converted from a fortress to a fortified city by the construction of an outer line of forts 5 mi. to 11 mi. from the city. After the beginning of World War I the Belgian government left Brussels for Antwerp on Aug. 18, 1914; and three days later the Belgian army took up a position behind the fortified lines. The siege of Antwerp began on Sept. 28, and after an intensive bombardment the city surrendered on Oct. 9, most of the population having already fled into Holland. On May 18, 1940, during World War II, the Germans again occupied Antwerp in their drive toward the channel ports. The fall of the city endangered the whole Belgian army, which surrendered ten days later after a heroic battle on the banks of the river Lys. Antwerp was later subjected to several severe bombardments, the worst taking place after its liberation by British troops in Sept. 1944. The harbour installations did not suffer severe damage. *See* also Index references under "Antwerp" in the Index volume. (E. F. B.; L. C. V.)

ANU (AN), a Babylonian deity, who, as the first figure in the triad Anu, Enlil (*see* BEL) and Ea (*q.v.*), came to be regarded as the father and king of the gods. Anu is prominently associated with the city of Erech in southern Babylonia, but the cult was transferred there in prehistoric times from Der east of the Tigris. At Erech he was closely associated with the worship of his daughter, the heaven goddess Inanna-Ishtar. The name signifies the "high one" and he was probably a god of the atmospheric region above the earth—perhaps a storm god like Adad (*q.v.*). In the period before Hammurabi, Anu was regarded as the god of the heavens and his name became in fact synonymous with the heavens, so that in some cases it is doubtful whether, under the term, the god or the heavens is meant. To Anu was assigned the control of the heavens, to Enlil the earth and to Ea the waters. The summing up of divine powers manifested in the universe in a threefold division represents an outcome of speculation in the schools attached to the temples of Babylonia, but the selection of Anu, Enlil and Ea for the three representatives of the three spheres recognized shows that each of the three must have been regarded in his centre as the most important member in a larger or smaller group, so that their union in a triad marks also the combination of the three pantheons into a harmonious whole.

In the astral theology of Babylonia and Assyria, Anu, Enlil and Ea became the three zones of the ecliptic, the northern, middle and southern zones, respectively. The purely theoretical character of Anu is thus still further emphasized, and in the annals and votive inscriptions as well as in the incantations and hymns he is rarely introduced as an active force to whom a personal appeal can be made. His name becomes little more than a synonym for the heavens in general, and even his title as king or father of the gods has little of the personal element in it. A consort, Antum (or as some scholars prefer to read, Anatum), is assigned to him, on the theory that every deity must have a female associate, but Antum is a purely artificial product and is really a title of Ishtar as queen of heaven. Anatum became the special name of Ishtar as "lady of battle." She was identified with the western Asian Ashratum. Anu and A-an-tum occur in the Hittite treaties of the 16th–14th centuries, but it is not certain that the Syrian-Canaanite war goddess Anat was borrowed from Babylonian Antum or Anatum. The Egyptian war goddess Anat is an Asian importation. *See* BABYLONIA AND ASSYRIA: *Religion: Herding Regions.*

ANUBIS, an ancient Egyptian god of the dead, represented in art by the figure of a man with the head of a jackal (or dog). In the early dynasties of the Old Kingdom he enjoyed a pre-eminent (though not exclusive) position as lord of the dead, but was later overshadowed by Osiris.

His particular concern was with the funeral cult and the care of the dead: hence he was reputed to be the inventor of embalming, an art he first employed on the corpse of Osiris. In his later role as the "conductor of souls," the Greco-Roman world sometimes identified him with the Greek Hermes, naming the composite divinity Hermanubis. (F. R. WN.)

ANURADHAPURA, a town of Ceylon and the administrative capital of the North Central province and the name of a district. Pop. (1953) town, 18,390; district, 229,282. The town is on the main railway from Colombo to the north. Nearby are two huge tanks, the ancient irrigation reservoirs of Tissa Wewa and Nuwara Wewa. Anuradhapura was established in the 5th century B.C. and became the second and most famous capital of the ancient Sinhalese kings. It was the seat of government at the time of the conversion of its king and his people to Buddhism by Mahinda, a son of Asoka. It suffered much during the earlier Tamil invasions, and was evacuated by the Sinhalese in A.D. 760 in favour of Polonnaruwa. Of its archaeological remains the most remarkable are its huge pyramidal *dagobas* (Buddhist relic shrines or stupas), constructed of small sun-dried bricks; its *pokunas*, or bathing pools; and the foundations of monastic buildings and palaces. Many of these monuments have histories going back at least to the time of King Dutthagamini (*c.* 100 B.C.). The city contains the famous Bo tree (pipal), believed to be originally a branch of the sacred tree at Buddh Gaya (*q.v.*) under the shade of which Gautama attained to Buddhahood, miraculously transported from India in 245 B.C. It is the oldest tree in existence of which there is any historical record. The city was completely abandoned to the jungle until it was rediscovered and opened up by the British in the middle of the 19th century; it has become the resort of many Buddhist pilgrims. It was decided in the mid-20th century to move the commercial, residential and administrative buildings of the town to a new position near the railway station, so that the site of the ancient capital could be turned into an archaeological park and place of pilgrimage. At Mihintale, 8 mi. E., there are many other important monuments.
(B. H. F.)

ANUS, the terminal aperture of the gastrointestinal tract. In man it is encircled by muscle fibres, the anal sphincter, which control the evacuation of feces. When contracted they throw the skin and mucous membrane into folds, giving a wrinkled appearance. Hemorrhoids or piles are due to dilated veins which project from the anus and often bleed.

See GASTROINTESTINAL TRACT; *see* also Index references under "Anus" in the Index volume.

ANVARI (AUHAD AL-DIN ALI) (d. *c.* 1190), Persian poet, accounted among the greatest panegyrists, was born in Abivard to the west of Merv early in the 12th century, studied at Tus and became the court poet of the Seljuk sultan Sanjar whom he attended constantly in Merv (the capital) and in the field of battle. When Sanjar died in 1157, Anvari fell out of favour and was hard put to it to find a patron. A prolific writer, his poems, which run to 770 pages in the Lucknow edition (1880), are marked by great technical skill and varied erudition, so that the Persian critic Daulatshah said of his verses that "they are difficult and require a commentary." His virtuosity is fully displayed in his formal odes. His lyrics, which are comparatively simple, exhibit tenderness and charm. He passed his last years in scholarly retirement, and died about 1190, probably at Balkh. His longest piece, a lament on the devastation wrought in northeastern Persia by in-

vading Ghuzz tribesmen, was translated into English in 1785 by William Kirkpatrick under the title *The Tears of Khorassan.* Another version was published in 1877 by E. H. Palmer in his *Song of the Reed;* he also translated Anvari's "Palinodia," a bitter satire of disillusioned old age.

See E. G. Browne, *A Literary History of Persia,* vol. ii, 365 ff. (1906; reprinted 1928); A. J. Arberry, *Classical Persian Literature,* pp. 113–119 (1958). (A. J. Ay.)

ANVIL, a mass of iron on which material is placed while being shaped under the hammer. The blacksmith's common anvil is made of wrought iron, often in the U.S. of cast iron, with a smooth working face of hardened steel. At one end is a projecting conical beak or bick for use in hammering curved pieces of metal; occasionally the other end is also provided with a bick, which is then partly rectangular in section. There is also a square hole in the face, into which tools, such as the anvil cutter or chisel, can be dropped, cutting edge uppermost. For power hammers the anvil proper is supported on an anvil block of great massiveness, and the block in turn rests on a strong foundation of timber and masonry or concrete. *See* FORGING.

ANVILLE, JEAN BAPTISTE BOURGUIGNON D' (1697–1782), distinguished French geographer and cartographer, was born in Paris on July 11, 1697. From an early age he continued, with greater effect, the reformation of cartography begun by G. Delisle, but he was also a classical scholar of repute and many of his memoirs and maps relate to ancient and medieval geography. He displayed exceptional judgment in the choice and use of his authorities and a detailed knowledge of measures of length, and he adjusted the results where possible to astronomically determined positions. His first important map was that of China, prepared from the surveys of the Jesuits. First issued with Du Halde's *Description de l'empire de la Chine* in 1735, it later appeared as the *Nouvel atlas de la Chine* in 1737. His map of Italy (1743) revealed numerous errors in the accepted maps of that country. Other important maps were of Africa (1749), Asia (1751), India (1752) and the world in hemispheres (1761). From the contemporary map of Africa, D'Anville removed many of the conventional and largely fictitious features of the interior, and his representation stood until the great explorations of the 19th century. His *Atlas général,* first published in 1743, was frequently revised. As well as being more accurate than those of earlier cartographers, the maps produced in his office were distinguished by their clarity and good lettering, while some were accompanied by valuable memoirs on the sources employed. His pre-eminence was recognized by his appointment as *premier géographe du Roi* in 1773. His published memoirs amounted to 78 and his maps to 211. Shortly before his death in Jan. 1782, his extensive geographical collection was acquired by the government and is in the Bibliothèque Nationale.

AN-YANG (or CHANG-TE), important archaeological site in northern Honan province where the Peking-Canton railway crosses the Huan river (36° 05′ N., 114° 20′ E.). Long known as the capital of the legendary Shang dynasty, both the site and the dynasty emerged into historical fact with the excavations by Chinese archaeologists of the Academia Sinica working from 1928 to 1937 under the leadership of Li Chi. Hsiao-t'un, about 10 mi. W. of present An-yang, was the actual palace site of the Yin or later Shang dynasty, *c.* 1401–*c.* 1123 B.C. A royal burial ground nearby has yielded many Shang bronzes, chariots, inscribed oracle bones, pottery and evidence of human and animal sacrifice. After 1950 further digging in this and other sections of north China enlarged the map of Shang influence and led to answers about the origins and development of the early Shangs and relations with their predecessors. Chinese scholars working in the area interpret the Shang as a period of urban growth with large workshops indicating occupational specialization, of use of imported materials like ivory and tin, and of slavery or human servitude in some form. An-yang declined when the succeeding Chou capital arose at Lo-yang. *See* also CHINA: *History.* (TE. H.)

ANYTE (early 3rd century B.C.), a poet of Tegea in the Peloponnesus, was so highly esteemed in antiquity that in the famous "Garland" composed by Meleager (early 1st century B.C.) the "lilies of Anyte" are the first poems to be entwined in the "wreath of poets." Her fame persisted, and Antipater of Thessalonica, writing during the reign of Augustus (27 B.C.–A.D. 14), places Anyte, whom he calls "a woman Homer," in a list of nine lyric poetesses. Of 24 extant epigrams assigned to her 20 are believed to be genuine. In her dedicatory epigrams her verse is akin to that of Theocritus and Leonidas, her contemporaries. Her dedications for fountains and to the nymphs of the springs show the Greek feeling for a quiet landscape that is so often illustrated in the Greek Anthology. She wrote epitaphs, perhaps literary rather than for actual use, on various animals. Unlike her contemporary, Nossis, she gives no suggestion of herself in her poems and never has love for a theme. Her love of nature and interest in animals mark her as thoroughly typical of the early years of the Hellenistic period.

ANZENGRUBER, LUDWIG (1839–89), Austrian playwright and novelist, most of whose works deal realistically with peasant life, was born in Vienna, Nov. 29, 1839. In 1870 his anticlerical play, *Der Pfarrer von Kirchfeld,* was widely acclaimed. Anzengruber won his greatest successes with plays of Austrian peasant life. *Der Meineidbauer* (1872) presents a gloomy picture, but *Die Kreuzelschreiber* (1872), *Der G'wissenswurm* (1874) and *Doppelselbstmord* (1876) are gay and witty comedies. *Das vierte Gebot* (1878) is a problem play which has affinities with Ibsen's *A Doll House.* Anzengruber also wrote a novel, *Der Schandfleck* (1877; revised 1884) and various other tales of village life. He died in Vienna on Dec. 10, 1889.

BIBLIOGRAPHY.—A critical edition of Anzengruber's works by R. Latzke and O. Rommel was published in Vienna, 1921–28. His correspondence was edited by A. Bettelheim (1902). *See* also A. Bettelheim, *L. Anzengruber,* 2nd ed. (1898); A. Kleinberg, *L. Anzengruber* (1921); K. Ermisch, *Anzengruber und der Naturalismus* (1927); F. Weber, *L. Anzengrubers Naturalismus* (1929); K. ANZHERO-SUDZHENSK, a town of Kemerovo *oblast* (province) of the Russian Soviet Federated Socialist Republic, U.S.S.R., lies on the Trans-Siberian railway at the northern limit of the Kuznetsk basin coal-mining area. Pop. (1959) 115,628. The urban districts of Anzherka and Sudzhenka were amalgamated in 1928, became in 1931 the town of Anzhero-Sudzhensk and grew with the development of the coal field which includes the mining of the high-quality sapropelite type of coal. Apart from mining, there are chemical industries using coal by-products for pharmaceutical manufactures, and factories for mining machinery. In the vicinity, quartzites and limestone, used in the Kuzbass metallurgical plants, and marble are also quarried. (R. A. F.)

ANZIKA, a former kingdom of central Africa, situated to the northeast of the kingdom of the Congo, whose province of Nsundi it adjoined. Portuguese travelers of the 15th and 16th centuries called its people *Anguicos* (*Anziques*). The name referred either to the Bateke people of the area ruled by the paramount chief Makoko, within the limits of the present Congo republic (former French territory) and Stanley pool as a whole, or to one of the tributary chiefdoms of the Makoko or, more generally, to the pagan cannibals north of the Congo river and the Christianized Congo kingdom. Anzika is said to have had a despotic king to whom many chiefs were subject. It was never subordinate to the Congo kingdom, being larger and more powerful according to Confalonieri, who based his descriptions on those of D. Lopez, F. Pigafetta and early Portuguese missionaries. Between 1568 and 1587 the Congo kingdom, under Alvare I, was defeated by hordes of Yaga and Anzika invaders.

The Anzika traded with the people of the Loango chiefdom, a vassal of the Congo kings. The country was famous for its copper

and red sandalwood and Anzika copper was sold to the earliest European traders by the Bavili tribe of Loango. The Anzika also exchanged slaves for cloth, ivory, salt and cowries. They used small arrows and bows covered with snakeskin and practised tattooing and circumcision.

ANZILOTTI, DIONISIO (1867–1950), Italian jurist, cofounder with Heinrich Triepel of the so-called positive school of international law, was born at Pescia, on Feb. 20, 1867. Professor of law at the universities of Palermo, Bologna, and finally Rome, 1911–37, he was appointed in 1921 a judge of the Permanent Court of International Justice of The Hague, where he presided from 1928 to 1930. In 1906 he founded in Rome with Ricci Busatti the *Rivista di diritto internazionale* ("International Law Review").

Anzilotti was one of the foremost representatives of modern international jurisprudence and, with Triepel, advocated a strictly legal approach to international law, based on a sharp distinction between the legal and the political and moral aspects of international relations. He died at Pescia on Aug. 23, 1950. (A. P. SI.)

ANZIO, a town of central Italy in the region of Lazio and province of Rome, lies on a peninsula jutting into the Tyrrhenian sea 38 mi. by road south of Rome. Pop. (1961) 17,453 (comm.) Anzio is a seaside resort with long sandy beaches and a small port for yachts and fishing boats. The Casino, known as the "Paradise on the Sea," was built in 1924. The Villa Spigarelli was reconstructed from a Roman villa and has frescoes, mosaic floors, statues and a grotto known as Coriolanus' tomb. Opposite is a Roman theatre and nearby a Volscian defense wall. At the end of the western beach are the ruins of the Roman port (A.D. 59) and Nero's magnificent villa. The medieval castle overlooks the port. The resorts of Nettuno and Lavinio are close by. Anzio and Nettuno are on the end of a branch line from Campoleone on the main Rome-Naples railway. In the summer months boats ply to the Ponza islands. Fishing is the chief industry; there is also a large soap and detergent factory and a sardine-canning plant. There is a thriving tourist trade.

The origins of Anzio are uncertain, legend declaring that it was founded by Antias, son of Odysseus and Circe. Known as Antium, it was the Volscian capital and traded with the near east. It was older than Rome, which conquered it in 341 B.C. It became an all-season resort, most wealthy Romans having villas there. Augustus was proclaimed "father of the Roman nation" while there; Caligula and Nero were born in Anzio. There are extensive Roman remains, and valuable works of art, including the famous statue of Apollo Belvedere, were found. After the fall of the western Roman empire, Anzio passed in turn under Gothic, Frankish, and papal rule, becoming part of the Italian kingdom in 1870. In World War II Allied forces landed at Anzio on Jan. 22, 1944, and formed a bridgehead, which, because of German resistance, did not link up with the main front until May 25, 1944. (EN. S.; F. FE.)

ANZOÁTEGUI, a state in northeastern Venezuela between the Caribbean sea and the Orinoco river, a typical llanos plains state containing, however, a few outliers of the northeastern highlands. Area 16,718 sq.mi.; pop. (1961) 382,002. Anzoátegui contains some of Venezuela's oldest settlements. Essentially a cattle-raising state, it also has important oil fields. Particularly outstanding among the latter is the Great Oficina area, composed of El Tigre, San Tomé, Campo Oficina and Campo La Leona fields and notable for light oils. Other fields in the state are Campo El Roble, Campo Santa Rosa, Campo San Joaquín and Campo El Guarico. Important pipelines connect these fields, along with small fields in the states of Monagas and Guárico, with Puerto La Cruz which exports crude oil and refines petroleum. There is coal at Naricual. Barcelona (*q.v.*) is the principal city and state capital. Important ports are Guanta and Puerto La Cruz. (L. WE.)

AOMORI, northernmost prefecture (*ken*) of Honshu, Japan. Area 3,711 sq.mi. Pop. (1960) 1,426,606. Aomori has a relatively poor, unstable agricultural economy that is handicapped by long, cold, snowy winters and poor drainage. Low-yielding rice fields and Japan's largest apple-producing area are features of western Aomori, while its eastern part specializes in dry grains and horses. Large-scale manufacturing is found only in Hachinohe, which produces chemical fertilizer and pig iron. In the mountainous interior are some of Japan's finest timber stands, mostly in national forests. Coastal and deep-sea fishing operations centre on Hachinohe, the leading fishing port, and Aomori.

The city of Aomori, located on Aomori bay, is the capital and largest city of Aomori prefecture. Pop. (1960) 202,211. One of Japan's most important transportation centres, it is the terminal for both northern Honshu rail lines and railroad ferry services across Tsugaru straits to Hakodate in Hokkaido. Although founded in the late 16th century, Aomori remained a local port until the opening of the Hokkaido ferry service (60 nautical miles long) in 1908. Strong winter winds make extensive breakwaters necessary in its artificial harbour. Its port is noted for shipments of lumber and fish and its coastal trade, mostly with Hokkaido. (J. D. EE.)

AORTA AND AORTIC VALVES. The aorta is the main systemic artery arising from the left ventricle of the heart. The blood passes through it to all parts of the body though the capillary and venous systems intervene between the systemic and pulmonic circulations. Its orifice is guarded by three semicircular pocket-shaped valves with their convexities toward the heart. The back pressure of the blood distends the pockets and closes the valves thus preventing regurgitation of blood into the left ventricle. The valve leaflets may become distorted by inflammation and permit leakage. Rheumatic fever may cause such valvular disease.

See ARTERIES; BLOOD VESSELS, SURGERY OF; CIRCULATION OF BLOOD; CIRCULATORY SYSTEM; HEART, ANATOMY OF. (F. L. A.)

AOSTA: *see* VALLE D'AOSTA.

APACHE, the general term used to denote six culturally related, Athapaskan-speaking Indian tribes of southwestern North America. Their ancestors probably entered the area from the north about A.D. 1100 as a unit, and tribal and linguistic differentiation occurred after arrival. The tribes encountered at the time of the first white contact were the Western Apache, the Chiricahua, the Mescalero, the Jicarilla, the Lipan and the Kiowa Apache. The process of differentiation was apparently still continuing at the time of first contact, for the Western Apache were found to be divided into five groups that were something less than separate tribes, yet more autonomous than bands. The Navaho (*q.v.*) have differentiated sufficiently to be considered a separate tribe. At the time of the North American occupation by the white man, the Apache ranged over what is now east-central and southeastern Arizona, southeastern Colorado, southwestern and eastern New Mexico, western Texas and northern Mexico. In physical type the Apache tends to be short, stocky, roundheaded and broadfaced.

The social organization of the Apache has a common core, but there are some interesting tribal variations. The family is uniformly a strong social and economic unit. At marriage the man and wife make their home at the encampment of the wife's relatives, and the husband is expected to work for them and show them deference in speech and behaviour. The Western Apache, doubtless influenced by their Navaho and Pueblo neighbours, are divided into a large number of named clans. A child automatically belongs to the clan of his mother. The Jicarilla tribe is divided into two bands or sections which have some reciprocal ceremonial functions. This moiety arrangement probably was stimulated by the example of nearby eastern Pueblo peoples.

The Apache were basically hunters and gatherers. Those on the western edge of the central plains hunted buffaloes. The reintroduction of the horse into the new world by the Spaniards and the rapid multiplication of this animal gave mobility to the Apache for the chase and for raiding. When first encountered, the Western Apache and the Jicarilla were supplementing their food supply of game and wild plants by cultivating corn and other vegetables on a modest scale. The Kiowa Apache, perhaps because of small numbers and military reverses threw in their lot with the Kiowa In-

dians of the plains, moving and camping with them. The Jicarilla, though they retained their separate territory, formed an alliance with the Southern Ute to counterbalance the Navaho threat.

After the American Civil War a determined attempt was made to limit the territories and movements of the Apache. Efforts, which failed miserably, were made to concentrate the Mescalero with the Navaho at Bosque Redondo on the Pecos river. Then there was an attempt, which also had to be abandoned, to station the Jicarilla with the Mescalero on a reservation farther to the south. Serious troubles arose when the Chiricahua were forced to relinquish their territories and were housed with the Western Apache. Groups of Chiricahua repeatedly left the reserve in fright or protest and were promptly pursued by army units. The last Indian war of this kind ended in 1886 with the surrender of Geronimo and his few remaining followers. This time the entire Chiricahua tribe was evacuated from the west and held as prisoners of war successively in Florida, Alabama, and at Fort Sill, Oklahoma, for a total of 27 years. In 1913 the members of the tribe were allowed to choose between taking allotments of land in Oklahoma or returning to the west to live in New Mexico on the Mescalero reservation. Approximately one-third chose the former course and two-thirds, the latter.

The Apache population totaled about 11,000 (1960s). The Western Apache live on the Fort Apache and San Carlos reservations in east-central Arizona. The Chiricahua, except those still living near Apache, Oklahoma, the Mescalero, and the Lipan live on the Mescalero reservation in southern New Mexico. The Jicarilla have a reservation in north-central New Mexico. The Kiowa Apache live on allotments of land in southwestern Oklahoma.

APALACHEE, an extinct tribe of American Indians belonging to the Muskogean linguistic stock. They have been known since the 16th century, and formerly ranged the country around Apalachee bay, Fla. The name is apparently Choctaw, meaning "people on the other side." About 1600 the Spanish Franciscans founded a successful mission among them, but early in the 18th century the tribe suffered defeat at the hands of the British; the mission churches were burned, the priests killed, and the tribe practically annihilated, more than 1,000 of them being sold as slaves. *See* Muskogean Indians.

See F. W. Hodge (ed.), *Handbook of American Indians North of Mexico* (1959).

APAMEA (Apameia), the ancient name of several towns in western Asia:

1. Apamea Cibotus (Apamea ad Maeandrum) was a city of Hellenistic Phrygia, the site of it being partly occupied by the modern Dinar, south of Afyonkarahisar in Turkey. Founded by Antiochus I Soter in the 3rd century B.C. and named after his mother, it superseded the ancient Celaenae, which stood at the source of the Marsyas. Apamea held a commanding position at the point where the great east-west trade route of the Seleucid empire left the Maeander valley for the Anatolian plateau. The name Cibotus (Gr. *kibotos*, "coffer," "ark") may have referred to its wealth or to some feature of its topography. It is possible that this name gave rise to the early Christian legend that the ark of Noah rested on the hill above the town. Having passed from Seleucid to Attalid and thence, in the 2nd century A.D., to Roman rule, it became a great centre for Italian and Jewish traders; it long claimed primacy among Phrygian cities. Disorganization in the 3rd century A.D. and the diversion of trade to Constantinople led to its decline. It was captured by the Turks in 1070 and finally destroyed by an earthquake. The older sections of Dinar are largely constructed from the remains of Apamea.

2. Apamea ad Orontem (in the valley of the middle Orontes in western Syria) was a treasure city and stud depot of the Seleucid kings, founded by Seleucus I Nicator. It was destroyed by Khosrau II of Persia in the 7th century A.D. and again by an earthquake in 1152. At the time of the crusades the site was known under the corrupted name of Famia. Extensive remains of streets and buildings may still be traced.

3. Apamea Zeugma (the modern Birecik in southeastern Turkey) was a town refounded by Seleucus Nicator on the site of the Til-Barsip mentioned in Assyrian inscriptions. On the high left bank of the Euphrates, it was approached by a bridge of boats (*zeugma*).

4. Apamea Myrlea (the modern Turkish Mudanya on the sea of Marmara) was so named when Prusias I of Bithynia rebuilt the earlier city of Myrlea.

5. Apamea in Babylonia is mentioned by Stephanus Byzantinus and by Pliny as having stood near the Tigris in the district of Mesene, but the identification of the site is uncertain.

6. Apamea Rhagiana was a Greek city in western Parthia, near Rhagae (the modern Rai or Rayy, in Iran). (Wm. C. B.)

APARRI, a municipality of the province of Cagayan, Luzon, Phil., on the east bank of the Cagayan River near its mouth, about 55 mi. N of Tuguegarao. Pop. (1960) 33,424. It was visited in 1572 by Gov. Guido de Lavezares and somewhat later by Luis Pérez Dasmariñas. In 1898 Filipino insurgents under Col. Daniel Tirona landed at the port; but in 1901 civil government under the U.S. was established. Aparri is the northernmost of the larger Philippine municipalities and is the port for much of northeastern Luzon. Ocean vessels cannot cross the bar at the mouth of the river, but interisland ships anchor in the river opposite Aparri. Principal products shipped are palay (rice), corn, copra, logs, and fish products. Both fishing and cattle raising are significant industries. The Christian inhabitants are mainly Ilocanos and Ibanags. Aparri was invaded by the Japanese on Dec. 10, 1941. U.S. forces occupied it in June 1945. (An. C.)

APARTHEID, an Afrikaans word meaning "apartness," the state of being separate or segregated. It is the name given by the Afrikaner Nationalist Party, in office in South Africa after 1948, to the policies that govern relations between the country's 3,000,000 white inhabitants and its 12,000,000 nonwhite, mainly African, inhabitants. It is also used to describe the long-term objective of the territorial separation of races that is advocated by Afrikaner church and intellectual circles.

The basic tenet of South African policy has always been the complete domination of state and society by the white population, and the two major parliamentary parties have vied with each other on how best to maintain white power. In practice, there have been few major changes since the Union of South Africa came into being in 1910 although terminology and idiom have changed considerably. Separation, segregation, and trusteeship are some of the terms that have passed in and out of use, and the word apartheid, which first gained wide currency during the 1948 election, is only the most recent.

Frontiersmen with attitudes born of exclusiveness and fear, white trade unionists determined to exclude unorganized and cheap nonwhite labour, industrialists equally determined to keep that labour unorganized and cheap—all these contributed to the establishment of a framework of segregation. Both before and after 1948 this framework was substantially strengthened. A vast range of industrial and service occupations was reserved exclusively for white workers and statutory powers were created to extend this policy in time of recession.

Ownership of land by Africans was limited to designated Native Reserves comprising only 13% of the land surface. Sexual relations and marriage between whites and nonwhites were made illegal. The right to vote was denied to nonwhite men, and all Africans were required to obtain permission before they could enter and remain in urban areas.

The advocates of apartheid declared that this legislation was necessary because they regarded Africans living in urban areas and on white-owned farms as aliens, temporarily residing in white society. Only in the Native Reserves, officially known as Bantu Homelands, could Africans hope to obtain political and economic freedom. After their 19th century conquest, a modified system of traditional authority was retained in the Reserves, together with

communal land ownership and the recognition of African family law. The Reserves have long been overcrowded rural slums and the adult males, because of poverty and taxation, are forced to spend their working lives as migrant labourers.

In the Transkei, the largest of the Homelands, the form, if not the substance, of political power is to be found. A prime minister and cabinet sit in a legislative assembly made up of 65 nominated members and 45 elected members, but its authority is limited and the South African president retains the right of veto. Critics who doubt that sovereignty will ever be transferred to the Transkei are even more skeptical about the application of this policy to the remaining Homelands which, like the Transkei, are not economically viable and have much smaller populations and territories. The policy of separate development is widely held to be an illusory one, and is regarded as a rationalization for maintaining racial discrimination.

Criticism of the apartheid policy by other member nations of the British Commonwealth led to South Africa's withdrawing from the Commonwealth in 1961. (S. Tr.)

APARTMENT HOUSE. In the United States an apartment house is a building containing more than one dwelling unit, each designed for housekeeping. In Great Britain a similar type of building is known as a block of flats, and each unit therein is called a flat. These units may be grouped in many ways and vary in size, appointments and facilities, providing a wide variety of living accommodations capable of satisfying the requirements of many different types of families. In the United States there was a steady increase in apartment building during the first quarter of the 20th century.

Communal dwellings and apartment buildings have existed for centuries. Among the North American Indians the most noted were the long houses of the Iroquois. These buildings ranged in depth from about 18 to 20 ft. and in length from 60 to 100 ft. They were divided into separate bays, one for each family.

The primitive buildings in the American southwest consisted of one-room houses built to form one continuous structure. Because of their locations on heights or in narrow river gorges, for ease of defense, the only possibility of expansion was upward. New houses would rise above the old, tier on tier, until heights of several stories were reached, each story of dwellings stepped back to give a terrace at each floor.

In the great cities of the Roman empire, because of urban congestion, the individual house had given way in early imperial times to the communal dwelling or apartment house, except for the residences of the very wealthy. Four stories were common, and six-, seven- or eight-story buildings were occasionally used.

Later, tall apartment buildings were erected in walled cities such as Paris and Edinburgh to hold increasing populations within inflexible boundaries; some of these buildings still standing in modern times in Edinburgh date from the end of the 16th century. In England houses were often converted from upper-middle-class residences to boardinghouses and finally to small flats. The only dwellings in England similar to the tall buildings in Edinburgh and on the continent were the chambers in the Inns of Court and the universities, until, in 1804, York house (the Albany), Piccadilly, was converted and extended to form bachelor apartments. There was no real development of the apartment building in England until the 1850s.

Early in the 19th century the Industrial Revolution enormously increased the populations of all the great industrial centres of the world. Populations doubled, tripled and quintupled in approximately 100 years. The result of this increase was a tremendous overcrowding, unaccompanied as yet by new conceptions of city planning or of dwelling design. People were simply crowded more and more closely into rooms, houses or blocks of tenements.

In the middle of the 19th century a new building type arose—the slum dwelling conceived and built as such, erected under municipal codes and accepted as standard practice. The typical New York "old-law" tenement, for instance—a type which started in the 1830s and consisted of apartments popularly known as railroad flats, the rooms placed in a row like railroad cars—probably holds a record for intensive use of space in the worst possible way. It is perhaps significant that sections of the cities that contained apartments for the rich were almost as densely covered and as poorly planned as those in the sections characterized by poverty. Much so-called model housing of this period was only slightly better. The Peabody foundation built five- and six-story tenements in London in 1864. In Paris a seven-story walk-up group which consisted of three buildings erected one behind the other on an interior lot received first prize in a competition in 1901. In Berlin Huber's society built an apartment building five stories high with its toilets in the yard. Few low-cost apartment buildings erected anywhere before 1918 show any signs of good design according to 20th-century standards.

In many continental cities, however, the second half of the 19th century witnessed great progress in the design of apartments for the upper-middle class and the rich. Particularly in Paris and Vienna this period produced a flood of apartment buildings which were excellently arranged for their purpose despite their cramped and difficult sites, although their standards of light, air and sanitation were still primitive.

From 1919 to about 1934 many large housing projects were constructed in Europe, a majority of them built either by the government or by public-utility societies with government aid. These projects included about 4,500,000 dwellings and showed tremendous advances in planning. In the United States a subsidized public housing program was started under the United States Housing act of 1937, by which the federal government made loans and subsidy grants to cities and other local governments to provide housing for low-income families. Much of this housing was in apartment buildings.

From about 1930 to the beginning of World War II many well-designed apartment buildings were erected, all over the world, and though these form only a small fraction of the total of apartment buildings existing, they established new standards, developed new methods and techniques and gave form to new and creative ideas.

The demand for rental housing after World War II was greater than ever before as the result of increased building costs, shifts in population and other causes. It was met in part by a vast amount of construction of multistory buildings in urban areas and by enormous developments of houses and apartments in suburban areas. The construction of apartment buildings in suburbs was almost entirely a 20th-century development, a result primarily of lack of adequate urban sites at economically feasible prices. Because of the availability of large tracts of comparatively inexpensive ground, suburban sites made possible the provision of many amenities not possible in costly urban centres, such as large open areas, providing views and privacy, outdoor sitting and play spaces and adequate parking facilities. These benefits, however, frequently were offset by longer travel time to and from work places and shopping districts.

APATITE is the name applied to a group of closely related phosphate-bearing minerals that are widely distributed in nature. Economically, the most important is the carbonate-bearing apatite of rock phosphate deposits, such as those of Florida, the Rocky mountain region, North Africa, the Ukraine and certain oceanic islands (*see* Mineral Phosphates). Low-grade phosphate rocks are of interest because of their content of uranium and vanadium.

Apatite is the hardness standard 5 in Mohs' scale. Its crystalline symmetry is limited to a sixfold axis and a plane perpendicular to it. The specific gravity is about 3.2, depending upon the chemical composition. The crystals may be brown, yellow, green, blue,

violet, white, or colourless.

Chemically, apatites are calcium phosphates having the type formula $Ca_{10}X_2(PO_4)_6$, where X is fluorine, chlorine or hydroxyl. Strontium and manganese may substitute for calcium within the crystal structure, thus giving rise to additional varieties. Carbonate-containing apatites related to fluorapatite and hydroxyapatite are known as francolite and dahllite, respectively. The indefinite term collophane is applied to seemingly noncrystalline substances with similar compositions. A rare, silicate-sulfate mineral, ellestadite, has essentially the same crystal structure, as does a mineral of intermediate composition, wilkeite.

B. M. SHAUB

BLACK APATITE CRYSTAL, SHOWING HEXAGONAL STRUCTURE, FROM ONTARIO, CAN. (ABOUT NATURAL SIZE)

Fluorapatite occurs as an accessory mineral throughout the compositional range in igneous rocks, frequently as small or microscopic crystals with hexagonal cross sections. Fluorapatite or hydroxyapatite occurs in many varieties of metamorphic rocks. Dark coloured crystals, sometimes exceeding a foot in length, occur in a matrix of coloured calcite in eastern Canada, for example. Though rarer, chlorapatite may be locally abundant, as it is in southern Norway.

The hard substance of vertebrate teeth and bones is chemically similar to carbonate hydroxyapatite and produces a similar X-ray diffraction pattern. During the process of fossilization the fluorine content tends to increase. (D. McC.)

APATURIA, an ancient Greek festival that was held annually by nearly all the Ionian towns. At Athens it took place in the month of Pyanopsion (Oct.–Nov.) and lasted three days, on which occasion the various phratries (clans) of Attica met to discuss their affairs. The name probably means the festival of "common relationship."

On the first day, called Dorpia, banquets were held toward evening at the meeting place of the phratries or in the private houses of members. On the second day, Anarrhysis, a sacrifice of oxen was offered at the public cost to Zeus Phratrios and Athena. On the third day, Koureotis, children born since the last festival were presented by their fathers or guardians to the assembled phrators, and, after an oath had been taken as to their legitimacy, their names were inscribed in the register.

APAYAO: *see* ISNEG.

APE, the general term for primates of the family Pongidae. The term anthropoid ape is generally used for those that most closely resemble man in appearance, anatomical features and probably genetic functions.

The apes include the gorilla, chimpanzee, orangutan and gibbon (*qq.v.*). The first three are sometimes referred to as great apes and are frequently classified together as the subfamily Ponginae. The gibbons and the closely related but much larger siamangs are placed in the subfamily Hylobatinae. The implied relationship of anthropoid apes to man and his ancestors leads to their inclusion together in the superfamily Hominoidea. (*See* PRIMATES: *Manlike Primates* [*Anthropoidea*]: *Apes and Men.*)

In addition to the living apes, numerous fossil forms have been discovered. Many of these remains are extremely fragmentary, the majority being represented by little more than teeth. The earliest date from the Oligocene. A number show affinities with the gibbons; the majority of the others are placed in the extinct subfamily Dryopithecinae. Of these, one group shows possible affinities with human ancestors and may eventually be grouped with the subfamily Australopithecinae of the family Hominidae. These man-apes have been traced back to the early Pliocene, indicating that the separation of the human line of descent from that of living anthropoid apes goes back at least 12,000,000 years. (*See* ANTHROPOLOGY: *Evolution and Racial Variation in Man.*)

Apes are similar both to men and old world monkeys in basic structure of the head and neck; to men only in the shoulder girdle and arms and in the lack of a tail. Their hip structure does not allow the characteristic human bipedal locomotion on the ground, although all apes can walk upright briefly. The apes are tropical forest dwellers of the eastern hemisphere. Gibbons and orangutans are arboreal brachiators, *i.e.,* they move through trees by swinging from branches by their arms. Chimpanzees and gorillas stay on the ground much of the time, and perhaps consequently have feet more similar to man. *See* MAN, EVOLUTION OF: *Comparative Anatomy.*

APELDOORN, a town in the province of Gelderland, Neth., is situated east of the sand hills of the Veluwe where they level off into the flat IJssel valley, 39 mi. by road east of Utrecht. Pop. (1960) 78,961. The town, with its brightly painted red brick houses, is mainly residential and industrial and has few buildings of historic interest. Het Loo, a royal palace built as a hunting lodge in 1686 by Jacob Roman for William III, is 1½ mi. N. It is surrounded by fine gardens. Apeldoorn is a tourist centre for exploring the Veluwe, a 15-mi.-wide area of heath and sand dune running southward for 25 mi. from the southeastern part of the IJsselmeer. The town is also a centre of road and rail communications and the canal from Dieren to Hattem runs through it. The chief industry is paper making, but the town is being developed as a general industrial centre. In World War II Apeldoorn was occupied by the Germans from May 1940 to May 1945.

APELLES (4th century B.C.), probably the greatest painter of antiquity. He lived in the time of Philip of Macedon and his son Alexander. He was of Ionian origin but became a student at the celebrated school of Sicyon, where he worked under Pamphilus. He thus combined the Dorian thoroughness with the Ionic grace. He became the recognized court painter of Macedon, and his picture of Alexander holding a thunderbolt ranked with the Alexander with the spear of the sculptor Lysippus. Other works of Apelles had a great reputation, among them the portraits of the Macedonians Clitus, Archelaus and Antigonus, the procession of the high priest of Artemis at Ephesus, Artemis amid a chorus of maidens, a great allegorical picture representing Calumny and the painting representing Aphrodite rising out of the sea. Of these works no copies survive, unless a painting of Alexander as Zeus in the house of the Vettii at Pompeii be considered as a reminiscence of his work. It is said that he attached great value to the drawing of outlines, practising every day. The tale is well known of his visit to Protogenes, and the rivalry of the two masters as to which could draw the finest and steadiest line. The power of drawing such lines is conspicuous in the decoration of the red-figured vases of Athens. Apelles allowed the superiority of some of his contemporaries in particular matters: according to Pliny he admired the way Melanthius spaced his figures, and Asclepiodorus' mastery of symmetry and proportion. He probably used only a small variety of colours and avoided elaborate perspective. Simplicity of design, beauty of line and charm of expression were his chief merits.

When the naturalism of some of his works is praised—for example, the hand of his Alexander is said to have stood out from the picture—it must be remembered that this is the merit always ascribed by untutored critics to works which they admire. In fact the age of Alexander was one of notable idealism, and probably Apelles succeeded in a marked degree in imparting to his figures a beauty beyond nature. Apelles was also noted for improvements which he introduced in technique. He had a dark glaze, called by Pliny *atramentum,* which served both to preserve his paintings and to soften their colour. There is little doubt that he was one of the most bold and progressive of artists.

APELLICON (d. *c.* 84 B.C.), a wealthy Greek book collector, was born at Teos and later became an Athenian citizen. During the First Mithridatic War, when Athens in revolt set up the peripatetic philosopher Athenion as tyrant, Apellicon supported him

and was disastrously defeated by a Roman commander when in charge of a force in Delos. He had previously bought from the descendants of Neleus of Scepsis in the Troad the libraries of Aristotle and Theophrastus which were in a damaged condition and may have contained the only copies of the Aristotelian treatises to survive, although this is uncertain. Apellicon was said to have published them with corrections and supplements. After his death, when Sulla captured Athens, the books were carried off to Rome where eventually they formed the basis of the famous edition by Andronicus of Rhodes. A keen bibliographer, who had once been found surreptitiously removing the originals of ancient decrees from the archive-depository in the Metroon at Athens, he owned a copy of the *Iliad* with the first line differing from that in the present text.

See I. Düring, *Aristotle in the Ancient Biographical Tradition*, pp. 382–395 (1957), for sources and references. (G. B. Kd.)

APENNINES (Appennino), a series of mountain ranges traversing peninsular Italy and forming the "backbone" of the country. The name probably derives from Celtic *pen*, a mountain top; it originally denoted only the northern section, from the Maritime Alps to Ancona. Polybius (*q.v.*) probably first applied it to the whole chain, extending the name as far as Marseilles. The total length is about 838 mi. and the width 25 to 80 mi.

Divisions.—The Apennines may be divided into three parts, northern, central and southern.

1. The Northern Apennines or Appennino Settentrionale extend from the western end of the Maritime Alps. The first section is called the Ligurian Apennines (Appennino Ligure), bordering the coast of the Gulf of Genoa. The rocks consist of limestones and Flysch (sandstones, marls, clays). The highest point is Monte Bue (5,840 ft.). The southern slopes rise steeply from the sea, their lower parts terraced for the cultivation of vines, olives, fruit and vegetables. The rugged coast has numerous resorts (*see* Riviera). The ranges are crossed by several passes, one of which (the Giovi) carries the main road and railway between Genoa and Milan. Numerous hydroelectric plants have been built, linked into the Italian grid-system.

The ranges then trend in a southeasterly direction as the Tuscan Apennines (Appennino Tosco-Emiliano). They culminate in Monte Cimone (7,103 ft.). The ranges are dissected by valleys draining to the Po and the Mediterranean, and are in places thickly forested with pine woods and on the lower slopes with sweet chestnut. The rocks are of limestone, sandstone and clay, and in places marble occurs, as at Massa-Carrara. The clays give rise to landslides during the winter rains, which can do much damage to roads and villages. Tuscany, however, is taken up by lower hills, divided from the Apennines by the Arno, Chiana and Paglia rivers. The Tuscan hills are rich in minerals and chemicals toward the west, which are not found in the Apennines proper. Railways cross from Pistoia to Bologna, from Florence to Faenza, and from Prato to Bologna through a long tunnel.

The Umbrian Apennines (Appennino Umbro) extend south to the Scheggia pass. They are lower, rising to 5,007 ft. in Monte Nerone, and are much dissected by the headstreams of the Tiber. A railway from Terni and Foligno crosses the mountains to Ancona on the east coast.

2. The central Apennines or Appennino Centrale extend southward as far as the valley of the Sangro as a series of broadly parallel ranges comprising the Roman Apennines (Appennino Umbro Marchigiano) and the Abruzzi Apennines (Appennino Abruzzese). The main summits are in the east, the Gran Sasso d'Italia (*q.v.*), culminating in Monte Corno (9,560 ft.), the highest point in the Apennines. There are extensive limestone plateaus, rugged and deeply dissected. From the easterly ranges, short rivers flow directly to the Adriatic. Between the parallel ridges lie long narrow valleys, mainly draining to the Tiber. The western margins of the central Apennines show signs of volcanic activity, with peaks such as Monte Amiato and the Alban hills (*q.v.*), and numerous crater-lakes; *e.g.*, Lake Bolsena. Near Lardarello a large geothermic power station utilizes steam produced by volcanic activity. The ranges are not easily crossed by railways, which follow the longitudinal valleys, but one line pursues a circuitous course from Rome via Avezzano to Pescara.

3. The southern Apennines or Appennino Meridionale extend southward as the Neapolitan Apennines (Appennino Napoletano) from the Sangro valley in a series of isolated blocks separated by broad depressions, rather than continuous chains. Most consist of rugged limestone, with bare rock where the winter torrents have gashed the hillsides. In the north the Montagna del Matese culminate in Monte Miletto (6,726 ft.); farther south are the Lucanian Apennines or Appennino Lucano (Monte Pollino, 7,375 ft.). Beyond the isthmus between the Tyrrhenian sea and the Gulf of Taranto are the Calabrian Apennines (Appennino Calabrese), made chiefly of granite, and the La Sila mountains which project into the "toe" of Italy toward the Straits of Messina. Numerous reservoirs have been constructed in the high valleys for irrigation and hydroelectricity. Volcanic activity is again evident around the Bay of Naples, notably Vesuvius (*q.v.*) and the Campi Flegrei. Further south this activity is represented in the Lipari Islands, with Stromboli and Vulcano. Numerous short rivers flow to the southern coasts. Several railways link the west and east coasts.

Character.—Many parts of the Apennines are snow-covered in winter, which is cold and bleak, though in summer the landscape is parched and arid. Winter torrents degenerate into strings of pools or dry courses in summer. Much was once thickly forested with pine, oak and beech, but a large proportion has been cleared during past centuries, so that the slopes, deprived of their protective tree cover, have been denuded of soil. Large areas are covered with poor evergreen scrub (macchie), and the higher parts, particularly in the central Apennines, carry summer pastures for sheep and goats. In recent years hillsides were terraced, pastures improved, and plantations of sweet chestnuts established on the lower slopes and of pines higher up. The eastern slopes overlooking the Adriatic sea are more gentle and fertile, but their disadvantage is the lack of water, since they are on the leeward side of the peninsula and receive less rain than the west. For the most part the Apennines are thinly populated. Settlements consist of villages of tall stone houses, either huddled in the valleys and depressions or perched on the hilltops. The people practise a poor type of agriculture. After World War II, the Italian government carried out several land-improvement schemes, particularly in the south of the peninsula, to create farms for landless peasantry. (F. J. M.)

Geology.—The Apennines form a part of the Alpine-Himalayan group of mountains (*see* Alps). They consist almost entirely of Triassic, Jurassic, Cretaceous, Eocene and Miocene beds, like the outer zones of the Alps. Remnants of older rocks may be seen in the Calabrian peninsula, Capo Circeo and the Island of Zannone, in the Apuane Alps, in the islands off the Tuscan coast and in the Colline Metallifere.

In the south the deposits from the Trias to middle Eocene consist mainly of limestones and were laid down, with a few interruptions, upon a quietly subsiding sea floor. Toward the end of the Eocene, the folding which gave rise to the existing chain became marked. The sea grew shallow; the deposits became conglomeratic and shaly; and volcanic eruptions began. Folding and elevation went on until the close of the Miocene period, when a considerable subsidence took place and the Pliocene sea overspread the lower portions of the range. Subsequent elevation, without folding, has raised the Pliocene beds in some cases to more than 3,000 ft., and they now lie almost undisturbed upon the older folded beds.

The last elevation led to the formation of numerous lakes, now filled by Pleistocene deposits. Both volcanic eruptions and movements of elevation continue to the present day around the shores of the Tyrrhenian sea. In the northern Apennines the elevation appears to have begun earlier, for there the Upper Cretaceous consists largely of sandstones and conglomerates. In Calabria the chain consists chiefly of crystalline and schistose rocks; it is the Mesozoic and Tertiary zone which has been sunk beneath the sea. Similar rocks are found beneath the Trias farther north in some of the valleys of the Basilicata. Glaciers no longer exist in the Apennines, but post-Pliocene moraines have

been observed in Basilicata. (J. I. P.)

Vegetation.—The Apennines are not generally rich in flora and have few endemic species by comparison with the Balkan or Iberian peninsulas. The greater part of the area is geologically Recent and, the range being cut off in Tertiary times by the sea on the east and west, plant immigration in more recent times must have taken place from the north either over the Alps or along their southern fringes. The low-lying areas have a Mediterranean type of vegetation and often form the boundary zones between eastern and western European types. The middle slopes carry types of vegetation ranging from Mediterranean to central European strongly influenced by Alpine conditions. Only in the south are there similarities to the true Mediterranean high mountain flora.

The Apennines are naturally wooded but the middle and lower slopes have for the most part been cleared of forests. Up to 1,000 ft. and, in favourable situations where the slopes are dry and sunny and there is chalk in the soil, even higher up, the dominant types of tree are the holm oak (*Quercus ilex*) and Mediterranean pine. Where deforestation took place the trees were often replaced by *maquis* and *garigue*. Olives, vines and vegetables are cultivated. Between 1,000 and 4,000 ft. there are deciduous oaks (*Quercus pubescens*, *Q. cerris*, *Q. petraea* and *Q. farnetto* in the south) and many other deciduous trees especially hop hornbeam (*Ostrya carpinifolia*), manna ash (*Fraxinus ornus*) and sweet chestnut (*Castanea sativa*). The sweet chestnut is cultivated over extensive areas. The dominant plant cover of the uninhabited subalpine zone (4,000–7,000 ft.) is beech with woods of beech and silver fir in the damper parts. Wide areas are covered with brushwood and pastures. Between the last two zones coniferous woods of black pine (*Pinus nigra*) occur especially in the southern part of the peninsula. At the highest level, such as the peaks of the Abruzzi and other peaks to the north and south, there is treeless alpine pasture. (We. L.)

Animal Life.—The mammals are similar to those in other mountainous areas of Europe. They include red deer, red fox, wildcat, otters in the rivers and mountain hares. There are also wild pigs and wolves except in the north. The brown bear is found in the Abruzzi National park, chamois in the central Apennines and the common porcupine in the south. Birds of prey include the golden eagle and, only in the south, Bonnelli's eagle. (Ma. Bu.)

APEX, SOLAR, the point of the heavens toward which the sun's motion relative to the mean of the stars is directed. Its position was indicated approximately by Sir William Herschel in 1783.

It is near right ascension 18^h, declination $+30°$, not far from Vega, but the position varies considerably according to the class of stars that has been chosen for reference. The speed of the sun's motion is approximately 12.4 mi. (20 km.) per second.

APHANITE, a name given to certain igneous rocks which are so fine-grained that their component minerals are not detected by the unaided eye. Although a few authorities still recognize the aphanites as a distinct class, most systematic petrologists have now discarded it and regard these rocks as merely fine-grained examples of other species.

Any compact, crystalline and fine-grained rock is frequently said to be aphanitic.

APHASIA: *see* Speech Disorders: *Aphasia* (*Dysphasia*).

APHELION, in astronomy, the point in the orbit of a planet or comet most distant from the sun. When the earth is at its aphelion in early July, it is about 3,000,000 mi. farther from the sun than when at its perihelion (*q.v.*) in early January. Corresponding terms for describing the most distant orbital point of bodies moving around centres of force other than the sun include apogee, apocenter and aposaturnium. The apogee of the earth's moon, for instance, is about 31,250 mi. more distant from the earth than its closest orbital point. *See* Moon: *Constants of Moon's Size and Motion.*

APHID, a plant louse, any of the minute insects belonging to the family Aphidae (formerly Aphididae) of the suborder Homoptera (order Hemiptera). They are among the most common insect pests of plants throughout the growing season, and there is hardly a species of plant, cultivated or wild, that escapes aphid infestation. Aphids (sometimes aphides) are soft-bodied insects measuring usually from one-sixteenth to not much more than one-eighth of an inch, although a few species may reach a quarter of an inch or slightly more. Because of their small size and coloration, resembling foliage, they are often difficult to detect and usually pass unnoticed. Many of them are beautifully coloured, ranging from white and creamy-gray through delicate shades of green, yellow and pink to deep red, various hues of brown and even jet black; they are variously marked and speckled with other colors and sometimes with white tufts or powdery wax. These tiny insects can do a tremendous amount of damage to heavily infested plants by constantly sucking up the plant sap needed for the vital functions and growth of plants. Instances are known in which beds of ornamental plants or large areas of field and truck crops were entirely ruined by aphids in a few weeks or even days.

FRAN HALL FROM NATIONAL AUDUBON SOCIETY

PLANT APHIDS (MACROSIPHUM AMBROSIAE) FEEDING ON STEM OF RAGWEED

Description.—Aphids are characterized by a pear-shaped body that is divided into a head, thorax and abdomen. Winged (alatae) and wingless (apterae) adults occur. The head in the winged forms is provided with three simple eyes (ocelli) and a pair of compound eyes. Aphids have two slender antennae, consisting of three to usually six segments. The last segment ends in a narrow process, the length of which, along with the number, shape, size and distribution of special sense organs (sensoria or rhinaria) over the antennal segments, is very useful in classification. The rostrum, or beak, is usually four-jointed, ensheathing four hairlike mouth parts that are capable of piercing plant tissue and penetrating intercellularly the food conducting channels (phloem) of vascular plants. The beak itself does not penetrate the plant tissue. In feeding, aphids inject a poisonous saliva into the plants, thereby producing various types of discoloration and malformations. Certain species (*Pemphigus* and *Eriosoma*) are notorious for a specific gall formation on poplars, elms and other plants. Several species act as vectors of different virus diseases of plants; moreover, all species provide avenues for bacterial infection via their feeding punctures.

The thorax consists of three segments. The winged aphids are provided with two pairs of delicate transparent wings, the hind ones much reduced, attached to the thorax. The wings are usually held in a gable rooflike position when the insect is at rest; however, some species keep them flat over the body. The thorax also has three pairs of jointed legs; each leg has a two-jointed end process (tarsus) fitted with paired claws. In the egg-laying (oviparous) females the long hind leg segment farthest from the body (the tibia) is usually swollen and studded with circular sensory porelike organs.

The abdomen is clearly eight-segmented (a ninth rudimentary segment is often concealed) and terminates in a tail-like cauda and an anal plate of significance in taxonomy. Each of the first seven abdominal segments has a pair of breathing pores (spiracles), one on either side. The abdomen may have dorsal and lateral tubercles of various shapes and sizes. The sixth abdominal segment, on its dorso-lateral margins, usually has a pair of special tubelike organs, possessed by no other insects; these organs, known as cornicles or siphunculi, emit gasses or sometimes a waxlike material. The cornicles were formerly often called honey-tubes because it was believed that the sticky, sweetish fluid known as honeydew of aphids was secreted through these tubes. Actually honeydew is a by-product of digestion, containing modified plant sap and sugars in excess of the aphid's needs, that is eliminated through the anus.

Natural History.—Aphid honeydew is fed upon by bees, wasps and flies and is eagerly sought by several species of ants. Certain ants care for flocks of aphids for the sake of this sweet fluid and will protect the aphids against predators and parasites. Some species of ants may build covering shelters from bits of plant material to safeguard the aphid colonies from rain and enemies, may transfer aphids from wilted plants to healthy ones to perpetuate colonies, and may chew off the wings of aphids to keep them from flying away.

Some species of aphid, for example, the corn-root aphid (*Anuraphis maidi-radicis*), are actually overwintered in ant nests; the cornfield ants (*Lasius americanus*) store eggs of the corn-root aphid and care for them throughout the winter. In the spring the young aphids hatch and are carried by the ants to the roots of weeds, where the aphids feed; later in the season, when corn is planted, the ants transfer their charges to the roots of corn. There are other interesting relations between aphids and ants, and the very existence of some species of aphids with incomplete life cycles, as in *Paracletus*, depends on protection by ants.

Ant-aphid relationships are set up only with aphids secreting the honeydew; those producing only a waxy secretion are ignored by ants.

In their biology, life cycles, method of reproduction, polymorphism (variation in form among members of a species) and instinctive heteroecy (migration to alternate hosts) aphids have no equals in the insect world. The life span of an aphid is rather short, two to four weeks, but amazingly complex in the seasonal life cycle of certain species. Aphids are known for a remarkable cyclic reproduction known as heterogamy, characterized by an alternation of several parthenogenetic generations, produced without mating during the growing season, with true sexual generation in the fall.

Life Cycle.—The life cycle typically begins with the fertilized eggs. They are laid singly or in small clusters late in fall about the bases of dormant buds and in crotches and crevices of plants, on primary hosts or egg-overwintering plants on which life history begins in the spring. The minute eggs (less than $\frac{1}{25}$ in. in length) are yellowish or greenish when freshly laid but soon become black.

Early in spring young aphids hatch from overwintered eggs, feed, grow by molting four times and reach maturity on the primary host in two or three weeks, depending on temperature. These forms, known as stem-mothers, are considered to be the first generation (fundatrix). Usually they are wingless, but stem-mothers of certain species of the subfamily Panaphinae are winged. The stem-mothers and the following generations reproduce parthenogenetically and ovoviviparously (eggs hatch in the parent's body and young are born live) until fall. Each female may give birth to three to seven living young nymphs daily for three or more weeks. Twelve to 20 generations may occur through the plant growing season, thus giving rise to enormous populations. The progeny feed either singly, in scattered groups or in dense colonies on stems, foliage or roots, depending on the species.

The second generation may be of winged or wingless forms. The winged forms of nonmigratory species in this and successive generations may disperse to plants of the same or related species for further propagation. In the case of the migratory species spring migrants (exules) are produced; these forms undertake with precise regularity a migration from the original primary host to oftentimes botanically strikingly different alternate or secondary hosts, usually annual plants or herbaceous perennials. (It is of interest to note that the primary hosts are perennial and evolutionarily older plants.) There may be from a few to usually ten or more wingless generations on secondary hosts.

In late summer or early fall, with the advent of cooler temperatures and shorter days, a special generation of winged individuals is produced on the secondary host. These aphids, known as fall migrants, disperse in search of primary hosts, where they may establish colonies. The progeny of the fall migrants may be wingless sexual oviparous females; these wingless females are joined by winged males that are produced on the secondary host. After mating, the sexual females lay their fertilized eggs, thus starting a new cycle. The foregoing account is the typical life cycle for the green peach aphid, *Myzus persicae* and for the potato aphid (*Macrosiphum solanifolii*). In other cases the fall migrants on primary hosts give birth to a wingless generation of parthenogenetic females known as sexuparae, as in the foxglove aphid (*Myzus solani*). These sexuparae in turn produce sexual males and females for further continuation of the life cycle.

The oviparous females in the majority of cases are wingless, though in some species (*e.g., Tamalia*) winged oviparous females are known. Most of the oviparous species lay several eggs, but in the subfamily Eriosomatinae only a single egg is laid by a beakless, nonfeeding female.

Males are small and may be winged or wingless. In some instances both kinds of males may occur in the same species, as in *Cepegillettea betulifoliae* and others.

A few species have anolocyclic reproduction in which the sexual part of the cycle is absent. Definite sexes may be lacking in their life history presumably because of some geoclimatic changes that occurred in the history of the earth and perhaps destroyed the primary hosts of these species. Also, when aphid species are newly introduced into a country not having the species of plant necessary for sexual reproduction of the particular aphids, an anolocyclic reproduction may develop. Such a case is that of the woolly apple aphid (*Eriosoma lanigerum*); this North American species after introduction into Europe began propagating only parthenogenetically on apples in the absence of its original primary host, the American elm.

Instinctive migration with the heteroeceous habit of feeding is distinctly advantageous to aphids in utilizing the more suitable plant sap of herbaceous plants during the summer, at a time when feeding conditions on primary hosts become unfavourable. Migration also provides a means of escape from predators and parasites. Continuous parthenogenetic reproduction without sexual forms is common in the tropics and is known to occur without interruption for several years in greenhouses, where uniform environmental conditions favour such reproduction.

Classification and Distribution.—The family Aphidae, divided into several subfamilies, belongs to the superfamily Aphidoidea, which also includes the family Phylloxeridae (*see* PHYLLOXERA). The Aphidae is represented by about 1,750 known species, and new ones are added to this number annually.

The relative abundance and diversity of aphids in the temperate zone of the northern hemisphere and the absence or very poor representation of native species in tropics and in the southern hemisphere indicate that aphids probably originated in the northern zoogeographic zones, the Nearctic and Palaearctic. North America, Europe and eastern Asia are rich in aphid fauna.

Phylogenetic (race history) studies suggest that the most ancient aphids inhabited evergreen trees, feeding on bark, young shoots and needles. Later they established themselves on broadleaf plants—mainly willows, poplars, birches, oaks, hickories and others—and eventually adapted themselves to perennials and annuals, infesting stems, leaves and roots. During this evolution aphids developed their marvelous adaptations, habits and complicated life cycle.

The past and present distribution of aphids is mainly governed by the parallel evolutionary development of plants and aphids, the presence or absence of suitable hosts and the complexity of ecological conditions, especially temperature and humidity, to which most of the aphid species are very sensitive. The majority of aphids depend on plants that grow in a moderate climate; a considerable fauna of specialized aphids, however, does exist in arid plant communities.

Economic Importance.—Aphids usually do not kill their host plants, but they frequently do reduce plant vigour, distort leaves and cause other malformations. These insects, in many stages of development, can often be found clustered in large numbers on new plant growth, on buds and on the undersides of leaves.

Damage wrought to crop plants by aphids is considerable: annual losses charged to the pea aphid (*Macrosiphum pisi*) run to about $4,000,000, and to the potato aphid (*M. solanifolii*) about $66,500,000. Heavy infestations often occur on many ornamental plants, among them roses, asters and many flowering bulbs.

Among other common economic species of aphids are: corn-leaf aphid (*Rhopalosiphum maidis*), spotted alfalfa aphid (*Therioaphis maculata*), green peach aphid (*Myzus persicae*), apple aphid (*Aphis pomi*), melon aphid (*Aphis gossypii*), woolly apple aphid (*Eriosoma lanigerum*), cabbage aphid (*Brevicorine brassicae*) and green bug (*Toxoptera graminum*).

Control.—Among the most efficient natural controls of aphids are the insect-eating species of ladybird beetles (Coccinellidae) that in their larval and adult stages may completely destroy large aphid colonies. Next in importance are the larvae (aphid lions) and adults of green lacewings (Chrysopidae), brown lacewings (Hemerobiidae) and the larvae of flower flies (Syrphidae). Parasites of aphids are found among small wasps of the families Braconidae, Chalcidae and Ichneumonidae. A fungus, *Entomophthora aphidis*, at the right combination of temperature and humidity may wipe out enormous populations of the pea aphid and other species in two or three days' time.

Aphids can also be controlled by chemical methods; insecticides such as Malathion, Rotenone, DDT and others, either as dusts or sprays, are effective. In many countries more detailed information on control may be obtained from governmental departments of agriculture and from local experimental stations.

APHONIA, or loss of voice, not due to a brain lesion, is a symptom of disease of the larynx or interference with the mechanism which controls its muscles. Of causes in the larynx itself, the commonest is acute catarrhal laryngitis, in the course of a cold, or after overuse of the voice. More serious diseases of the larynx are diphtheria, tuberculosis, syphilis, and cancer, each of which may produce hoarseness or loss of voice when it attacks the vocal cords. Causes outside the larynx are masses pressing on the laryngeal nerves, such as tumours of the thyroid gland and aneurysms of the aorta, and brain disorders giving rise to spasm or paralysis of the laryngeal muscles. Aphonia may be a manifestation of hysteria. *See* also LARYNGITIS; THROAT, DISEASES OF.

APHORISM, a principle expressed tersely in a few telling words or any general truth conveyed in a short and pithy sentence, in such a way that when once heard it is unlikely to pass from the memory. The name was first used in the *Aphorisms* of Hippocrates, a long series of propositions concerning the symptoms and diagnosis of disease and the art of healing and medicine. The term came to be applied later to other sententious statements of physical science, and later still to statements of all kinds of principles.

Aphorisms have been especially used in dealing with subjects to which no methodical or scientific treatment was applied till late, such as art, agriculture, medicine, jurisprudence and politics. The *Aphorisms* of Hippocrates form far the most celebrated as well as the earliest collection of the kind. The first aphorism, perhaps the best known of all, which serves as a kind of introduction to the book, runs as follows: "Life is short, art is long, opportunity fugitive, experimenting dangerous, reasoning difficult: it is necessary not only to do oneself what is right, but also to be seconded by the patient, by those who attend him, by external circumstances."

Another famous collection of aphorisms is that of the school of Salerno in Latin verse, in which Joannes de Meditano, one of the most celebrated doctors of the school of medicine of Salerno, summed up the precepts of this school. The book was dedicated to a king of England. It is a disputed point as to which king, some authorities dating the publication at 1066, others assigning a later date. Another collection of aphorisms, also medical and also in Latin, is that of the Dutchman Hermann Boerhaave, published at Leyden in the year 1709; it gives a terse summary of the medical knowledge prevailing at the time and is of great interest to the student of the history of medicine.

APHRAATES (Syriac AFRAHAT; Persian FARHAD) (fl. in the 2nd quarter of the 4th century), commonly known as the Persian Sage, was a Syriac homilist and one of the earliest fathers of the Syriac church. The few certain facts about his life are gleaned from his Homilies. A convert from paganism, he became a monk, probably also a bishop, for he speaks of the laying on of his hands, and he had a seat at the council of Seleucia and Ctesiphon (344), where he drew up the encyclical letter (Homily 14). A marginal note in a 14th-century manuscript in the British museum, London, calls him bishop or head of the convent of Mar Matthew near Mosul. Probably at some ecclesiastical advancement, he seems to have adopted the name Jacob, which as early as 496 led Gennadius of Marseilles to attribute the Homilies to Jacob of Nisibis (d. 338), and explains the attribution to the latter of the Armenian version published by Antonelli (1756). Aphraates lived during the persecutions of Shapur II (*q.v.*), which are alluded to in the Homilies. There are 23 Homilies, each beginning with a successive letter of the Syriac alphabet. Ten were produced in 337, 12 in 344, and as appendix a Homily, beginning with the first Syriac letter, was added in 345. They are treatises on the Faith, an ordered exposition furnished to an enquirer, orthodox as later Jacobites and Nestorians attested, but free from Greek theological influence. "To him Christianity was the revelation of a Divine Spirit dwelling in man and fighting against moral evil, not first and foremost a tissue of philosophical speculation about the nature of the Divinity in itself." (F. C. Burkitt, *Early Eastern Christianity*, John Murray Publishers Ltd [1904].) Several Homilies are directed against the Jews and show knowledge of Jewish exegesis. His works are important for the light they throw on 4th-century Christianity in Persia; even their obscurities may reflect the need for caution amid persecution. His practice of full biblical quotation affords valuable evidence for the form of text used then. Burkitt held that Aphraates quoted from the *Diatessaron*, but A. Vööbus, *Studies in the History of the Gospel Text in Syriac* (1951) indicates that it was from a *tetraevangelion* (four Gospels) of the Old Syriac type.

(W. D. McH.)

APHRODISIAC, any of various forms of stimulation used chiefly to arouse sexual excitement. Aphrodisiacs may be classified in two principal groups: (1) psychophysiological (visual, tactile, olfactory, aural); and (2) internal (foods, alcoholic drinks, drugs, love potions, medical preparations).

By far the more important is the second group, as the preparation of erotic dishes has played a tremendous role in the sexual history of man. In spite of their vast popularity, almost no scientific studies have been written about them; most writings on the subject are little more than unscientific compilations of traditional material. Of the various foods to which aphrodisiac powers are traditionally attributed, fish, vegetables and spices have been the most popular throughout history. None of these foods, however, contains any chemical agents that could effect a direct physiological reaction upon the genitourinary tract, and it must be concluded that the reputation of various supposedly erotic foods is based not upon fact but upon folklore.

Since food cannot produce sexual desire biochemically, the question at once arises of how it has happened that man has, for centuries, in all parts of the world, attributed such powers to foods. It should be remembered that a large number of the plants, vegetables, spices, etc., that are supposed to be aphrodisiacs acquired their reputation many centuries ago, when there was no scientific information available. In those early times the guiding principle that determined the attributes of plants and other foods was the doctrine of signatures. This refers to an ancient belief in the therapeutic efficacy of resemblances. Thus if a plant resembled the genitalia, it possessed, so it was reasoned, sexual characteristics

and powers. The best example of this visual identification is the name of vanilla, which originally meant vagina (from the Spanish *vainila*, the diminutive form of *vaina*, "pod," "sheath," "vagina," from the Latin *vagina*, "sheath," "vagina").

One of the subtlest aspects of the question of foods as aphrodisiacs, which has been practically ignored by all writers on the subject except the German nutritionist H. Balzli, is the psychophysiological reaction that a well-prepared meal of subtly seasoned foods can have upon the human organism. The combination of various sensuous reactions—the visual satisfaction of the sight of appetizing food, the olfactory stimulation of their pleasing smells and the tactile gratification afforded the oral mechanism by rich, savoury dishes—tend to bring on a state of general euphoria conducive to sexual expression. In this connection might be cited the famous French *cabinets particuliers*—luxurious private dining room-boudoir suites featured by many Parisian restaurants of the 19th century.

With the exception of alcoholic drinks and certain narcotics such as marijuana, which may lead to sexual excitation through depression of inhibitory centres, modern medical science recognizes a very limited number of aphrodisiacs. These are, principally, cantharides and yohimbine. Yohimbine is a crystalline alkaloid substance derived from the bark of the yohimbé tree (*Corynanthe yohimbe*) found in central Africa, where it has been used for centuries by Africans to increase sexual powers. Although it has been promoted as an aphrodisiac, most investigators feel that any clinical change in sexual powers after its use is probably due to suggestion, since stimulatory effects are elicited only with toxic doses.

BIBLIOGRAPHY.—By far the most authoritative survey is M. Hirschfeld and R. Linsert, *Liebesmittel* (1930), a unique discussion of the question from a modern medical viewpoint. Informative studies, not treating the subject from the all-important physiological viewpoint, are: H. S. Denninger, "A History of Substances Known as Aphrodisiacs," *Annals of Medical History*, vol. ii, pp. 383–393 (1930); A. Costler and R. Willy, *Encyclopaedia of Sexual Knowledge*, ed. by Norman Haire, pp. 355–386 (1936); H. Ellis, *Studies in the Psychology of Sex*, vol. iii (1936); G. R. Scott, *Encyclopedia of Sex*, pp. 22–23 (1939); A. F. Niemoeller, *Aphrodisiacs and Anti-Aphrodisiacs* (1945). Important studies for various regions are: R. Schmidt, *Beiträge zur indischen Erotik*, pp. 833–855 (1902); E. Malone, *The Plays of William Shakespeare*, vol. viii, T. Hopfner, *Das Sexualleben der Griechen und Römer* (1938); H. Licht, *Sexual Life in Ancient Greece* (1934); B. Stern, *Medizin, Aberglaube und Geschlechtsleben in der Türkei*, vol. 2 (1903). *See* also H. Balzli, *Gastrosophie: Ein Brevier für Gaumen und Geist* (1931), an extraordinarily sensitive evaluation of the subtle yet profound relationship between food and sex; and C. F. Heartmann, *Cuisine de l'amour* (1942). (D. Md.; F. O. K.)

APHRODITE, best known as the Greek goddess of sexual love and beauty, identified by the Romans with Venus (*q.v.*). The familiar picture of the goddess who "overcomes all mortal men and immortal gods with desire" occurs first in book 14 of the *Iliad* and provides the archetype for most later Greek poetry. To her sphere of influence Hesiod assigns "girlish dalliance, smiles, deceits; sweet pleasure, love, and gentleness" (*Theogony*, 205–206). The Homeric Hymn to Aphrodite extends her power to all living things save three virgin goddesses. Among the early lyric poets she came to stand for a cultural ideal, the life devoted to youthful beauty and love: Sappho, ardent and sensitive, honours her above all others, while Mimnermus asks, "What is life without golden Aphrodite?" From the very first her own person was the paradigm of female beauty; Achilles in book 9 of the *Iliad* says that he would not marry Agamemnon's daughter, "even if she rivaled golden Aphrodite in beauty." The statue of Aphrodite at Cnidos, considered by Pliny the Elder the finest statue ever made, is Praxiteles' attempt to capture this vision in marble. The Venus de Milo continues the tradition; in fact, most of Aphrodite's sculptural types are devoted to one or another aspect, lofty or sensual, of her beauty. As goddess of beauty Aphrodite was associated with the Charites (usually translated Graces); in the eighth book of the *Odyssey* they bathe, dress and anoint her. Hesiod and later epic poets connected Aphrodite with the Horae (Seasons), suggesting her power over natural as well as human beauty.

Homer and Hesiod, according to Herodotus, fixed for the Greeks the nature and duties of their gods; they must have exerted considerable influence over the mind of the average worshiper. In very few cult shrines, however, is there found evidence that Aphrodite was primarily the love goddess in the Homeric sense. This suggests that some of her cults may reflect conceptions that antedate Homer—that Homer made her the love goddess. Certain forms she took have nothing to do with love: she is sometimes the protectress of sailors, sometimes armed, occasionally bearded. Of most of her local cults little is known directly, but what evidence there is indicates that her sphere was the act of love rather than the passion. We should expect the function of such a goddess to be the promotion of human, perhaps vegetative, fertility, and we are not entirely disappointed. In Hymettus, near a temple of Aphrodite, there was a spring where women drank who wished to conceive or who wanted an easy childbirth. In Hermione, women sacrificed to her before marriage, perhaps for satisfactory sexual relations but more reasonably for their own fecundity. Spartan mothers upon the betrothal of their daughters sacrificed to Aphrodite Hera—a fusion of Aphrodite with the marriage goddess—doubtless for similar reasons. In Attica, Aphrodite was associated with the Moirai (Fates) and the Genetyllides, goddesses who presided over birth. Phallic symbols, appropriate to fertility worship, have been found dedicated to her. In Corinth, Cyprus and Eryx in Sicily, she was worshiped by religious prostitution: either all women gave themselves once to a stranger before marriage, or certain women devoted themselves continually to her service. Aphrodite's religious prostitutes were probably intended to promote fertility, as they were in other ancient cults; in Eryx the goddess probably presided over vegetative growth.

Clearly the gulf between sexual desire and human fertility is not vast, and it may be supposed that worshipers at Aphrodite's shrines in later days felt little conflict between Homer's conception and their own. But to early poets, probably voicing courtly opinion, the cult seems to have had a somewhat different appearance. In mythology Aphrodite is often found associated not with human love in general but with its darker side: rape (in the myths of Paris and Helen, of Theseus and Ariadne), adultery (in Aphrodite's own affair with Ares while married to Hephaestus) and incest (in the myths of Hippolytus and Phaedra, of Cinyras and Myrrha); the list could be considerably extended. Only one mortal couple in Homer knows Aphrodite's favour, Paris and Helen; she has no influence over Achilles and Briseis, Hector and Andromache or Odysseus and Penelope. In most of the *Iliad* she is the goddess of seduction and rape. It may be reasonably supposed that Homer inherited, along with the obviously pre-Homeric myth of Helen's rape, this concept of Aphrodite, and that in book 14, modifying tradition, he made her the goddess of love. Even here she aids in Hera's deceit and seduction of Zeus, but her sphere of influence is extended and the nature of that influence treated far less harshly than elsewhere. In one line of book 5 Homer even associates her with marriage. The pre-Homeric goddess of rape, toward whom we sense much antagonism in the *Iliad*, may well represent the Greek nobility's estimate of the cult goddess of sexual intercourse. Ritual prostitution, for instance, is not likely to have aroused much enthusiasm among those who professed heroic values.

It is not from Greek cult and myth alone that scholars have sought clues as to the early nature of Aphrodite. Most are inclined to think that her worship came from the east after the Greeks had made their home on the peninsula to which they later gave their name. The cult of Aphrodite in the Cyprian town of Paphos was of considerable prominence in pre-Homeric times, since the *Odyssey* speaks of Paphos as if it were her native city. In Hesiod's *Theogony*, though literally born from the sea, she comes to land first on Cyprus. She was called Cypris (Lady of Cyprus) and Cyprogeneia (Cyprus-born) very early. The Greeks probably first met her there during their penetration of the eastern Mediterranean in the latter half of the 2nd millennium B.C. As her worship was carried westward she may have absorbed features of deities already established. This seems certainly to have occurred on Mt. Ida in the Troad (the northwest corner of Asia Minor, flanking the Hellespont), for the goddess there bears many resemblances to the Great Mother of Asia Minor, best known under the name Cybele.

If we attempt to venture beyond the Cyprian cult in the search

for origins the path becomes much darker. It was formerly felt that Aphrodite was only another form of a mother goddess common to the Semitic near east generally but worshiped under varying names in different places: Ishtar in Mesopotamia, Astarte and Asherah (Ashtoreth) in Syria, and so forth. The Phoenicians were said to have brought this goddess to Cyprus, Cythera (where there was an ancient cult of Aphrodite) and Corinth. This theory cannot be right, though it must not be rejected entirely. Aphrodite's presence on Cyprus almost certainly antedates the Phoenician colonization, and many features of her cult there may have received Anatolian rather than Semitic influence. Her Paphian worship was carried on by Cinyradae, whose ancestor Cinyras was said to have founded the cult there. Later myths make Cinyras a Syrian and father of Adonis, a Syrian vegetation god; these myths have been used as evidence for Aphrodite's Syrian origin. But the only reliable tradition assigns Cinyras' provenience to Cilicia in southern Anatolia. Adonis and Aphrodite were indeed often associated, but Adonis may be a late Phoenician replacement for earlier native Cyprian deities; the evidence is slight, moreover, for Adonis' worship at Paphos. The Paphians themselves were said by Herodotus to have derived their temple type from Ascalon in Phoenicia. The type was known in the Minoan-Mycenaean culture, long before the Phoenicians were active; but the Mycenaeans may well have derived this type from Syria. The fact that Aphrodite's "statue" at Paphos was a stone in the shape of a pointless cone has been adduced to show Semitic influence, but actually the aniconic representation, rare among the Greeks, who of course preferred anthropomorphic forms, was common all over the pre-Greek Aegean.

Certain of Aphrodite's features must be considered Semitic. Her unusual epithet Urania (heavenly, daughter of Uranus) points to the Semitic goddess of the heavens, actually called Urania by Herodotus. The maritime Aphrodite, protectress of sailors, may derive this function from the Syrian Asherah, called Asherah "of the sea." Some scholars derive Aphrodite's name from Asherah, the Greeks assimilating the foreign word to a Greek root *aphro-* ("foam") and later calling her the foam-born goddess. Aphrodite's familiar symbol, the dove, seems near eastern in origin.

In the town of Amathus, near Paphos, a bisexual form of Aphrodite was worshiped. A terra-cotta figurine dating from the early 7th century and showing the bearded goddess rising from what seem to be testicles was found near Corinth. Hesiod tells a myth clearly related to this figurine. Cronus, having castrated his father Uranus, cast the genitals into the sea, and from the foam that flowed from and surrounded them Aphrodite was born. When she first stepped ashore on Cyprus grass sprang up under her feet, suggesting that she possessed power over the life of vegetation. Though Hesiod's concept of Aphrodite's character is Homeric, his myth is not; in Homer Zeus and Dione, rather than Uranus and the sea, are Aphrodite's parents. Hesiod's birth story appears invented for the fertility goddess. There are many indications that the Amathusian bisexual deity represented by the terra-cotta figurine was a vegetation deity: it is the role played by most other ancient eastern bisexual divinities; the vegetation god Adonis was worshiped at Amathus; an inscription refers to sacrifices to Aphrodite to secure the fertility of the crops. There was a grove of Aphrodite Ariadne there, Ariadne (*q.v.*) being originally an Aegean vegetation goddess; the cults appear to have fused at an early date, before Ariadne became a mere mortal. In honour of Aphrodite Ariadne, a young man dressed in women's clothes and imitated the cries of a woman in childbirth; though the exact significance of this rite is unknown, it surely points to a fertility cult. Aphrodite's tomb was shown at Amathus, and a dying deity is almost always a vegetation god.

The time of Aphrodite's movement westward is uncertain. Her name has not yet been read on the Mycenaean tablets. A naked dove-goddess found on ornaments at Mycenae has been called Aphrodite, and her nudity points to eastern influence, but it is not known whether or not the ornaments had cult significance.

Aphrodite probably preserved her function as a fertility goddess when she came to Mt. Ida in the Troad, for such was the Great Mother whose worship she there absorbed. The Homeric Hymn, with its rich sensuousness, its vision of the goddess' great splendour, and especially the train of wild animals accompanying her, draws heavily upon Aphrodite's predecessor. A much-disputed point is whether Aphrodite preserved her function as a vegetation goddess when she came to the Greek mainland. Her bearded form and ritual prostitutes occur at or near Corinth, where also there was a cult of Aphrodite the Dark, an earth goddess who was probably associated with vegetation. But these may be ritual survivals from the eastern cult; her domain may be no more than human fertility. Simonides praised certain Corinthian women, probably Pindar's "hospitable young ladies," the ritual prostitutes, for their efforts during the Persian invasion. Aphrodite seems thus to have had a wide range of duties there, and in fact her statue on Acrocorinth showed the goddess armed. This attribute is recorded for the early cult on Cythera, and may be an oriental feature; the fact that Aphrodite was called Urania at Corinth also points eastward. Aphrodite was worshiped together with Eros (the Roman Cupid) on the north slope of the Athenian acropolis, with the designation, quite inappropriate to the spot, of "in the gardens." This title and the presence of phallic symbols have suggested that Aphrodite here retained her vegetative character. Eros seems to be the god of divine procreation in the *Theogony*, but his Hesiodic associations are not with vegetation, and in Athens above all we must be conscious of poetic influence. The title "in the gardens" may merely stress Aphrodite's sway over natural beauty; the phallic symbols may indicate human fertility. This is apparently the significance of the myth that Aegeus founded the Athenian cult of Aphrodite Urania in the belief that she was responsible for his childlessness. The Athenians also had a temple of Aphrodite Pandemos ("of all the people"), whose temple was purified by the sacrifice of a dove. The dove attribute is probably eastern, but we may well wonder whether anything more than the symbol has here migrated to Greece.

The imagination discernible in the Cyprian cult apparently failed to persist in Aphrodite's cults in Greece, which are generally uninteresting. But poetry and art were not bound to the ritual tradition; Plato could use the terms Pandemos and Urania to distinguish between common and heavenly love in utter despite of their cult significance. Aphrodite was very seldom a cult goddess of beauty; Greek poets and sculptors made her the ideal feminine type. Eastern features, though modified, do not always disappear: the bisexual fertility deity becomes Hesiod's foam-born goddess, then the artistic type of Aphrodite Anadyomene ("rising from the waves"), while traces of the vegetation goddess may persist in such symbols as the apple in the hand of the Venus Genetrix (Mother) in the Louvre. To Euripides, Aphrodite represented human passion, overwhelming in intensity and potential destructiveness, yet was also "she who from the streams of Cephissus breathes fragrant breezes over Attica," who sends "the loves that are seated by the throne of wisdom, fellow workers in all virtue" (*Medea*). Aeschylus calls her part-cause of the love between heaven and earth, the universal power of procreation, and such she remains in the poem of Lucretius, "sole ruler of all the world," without whom "no thing can win to the shores of light, to joy and love."

APION (fl. 1st century A.D.), Greek grammarian and commentator on Homer, who was born at Oasis in Libya, is the original source for the story of Androcles and the lion. This was taken by Aulus Gellius from his *Aiguptiaka*. He was head of the school at Alexandria and led a deputation sent to Caligula (in A.D. 38) by Alexandrians to complain of the Jews. References to this deputation are to be found in the *Legatio ad Gaium* of Philo who led a Jewish deputation to Rome in A.D. 39–40. The charges he

brought in his books against the Jews were answered by Josephus in his *Contra Apionem.* Later he settled at Rome and taught rhetoric.

For fragments of his *Glossai Homerikai, see* F. G. Sturz (ed.), *Etymologicum Gudianum* (1818).

APIS, the classical Greek form of *Hape* or *Hapi,* the sacred Egyptian bull deity worshiped at Memphis. His cult was of early origin: the festival of the "running forth of Apis" was celebrated in the Archaic period, probably by the time of the first kings. Like other bull deities in Egypt, Apis must at first have been a fertility god, concerned with the propagation of flocks and herds, but he became associated with Ptah (*q.v.*), the paramount deity of the Memphite locality, and also with Osiris (*q.v.*) and Sokaris, gods of the dead and of the underworld. As "the living soul of Osiris" he was frequently known as User-Hapi (Osiris-Apis). As Apis-Atum he was associated with the solar cult and is often shown on monuments and in figurines with the sun-disk between his horns.

Much of what is known about Apis comes from Greco-Roman writers. He was black and white and distinguished by special markings. Some said that he was begotten by a ray of light from heaven, others that he was sired by an Apis bull. When a sacred bull died, the calf which was to be his successor was sought and installed in the Apieion at Memphis with great rejoicing, in a stable near the temple of Ptah; his mother was housed nearby. In the court adjoining he was daily let out to exercise, and here he could be glimpsed by visitors. His priests drew omens from his behaviour, and his oracle had a wide reputation. The cult of the Apis bull was particularly favoured by the Saite kings.

When an Apis bull died, it was buried with great pomp in the necropolis at Saqqarah, in underground galleries known in the classical world as the Serapeum. In chambers opening off a central corridor, the mummified bulls were laid in huge sarcophagi of limestone or granite of many tons' weight.

It was probably at the Memphite Serapeum, to which pilgrims flocked, that the worship of Sarapis (*q.v.*) arose in late times. Transplanted to Alexandria by Ptolemy I Soter, it spread among the Greeks and Romans to become one of the most universally popular oriental cults; but the bearded, Zeuslike figure of Sarapis the Healer had more in common with the syncretistic deities of the Hellenistic world than with the ancient bull gods of Egypt.

APOCALYPSE OF ST. JOHN THE APOSTLE: *see* REVELATION, BOOK OF.

APOCALYPTIC LITERATURE. The word "apocalypse" is Greek in origin and means "unveiling" or "uncovering." It was first used to describe a vision (*cf.* Dan. viii, 1) and was then applied to books relating it. The type of literature called apocalyptic professes a secret knowledge of future events, in particular of the time and manner of the End, and is able to disclose these secrets by superhuman means. The Jewish apocalyptic literature is of considerable significance both for Judaism and for Christianity. It gives interesting insights into that section of Judaism that lay outside the rabbinical schools and it also casts light on a number of important developments in religious beliefs that took place during the intertestamental period and that are reflected in the New Testament Scriptures. Apocalyptic is exemplified in the Bible by the Book of Daniel (*q.v.*) and also by the Book of Revelation (*q.v.*) (Gr. *Apokalypsis*), which, though Christian, reflects the pattern of Jewish apocalyptic writings.

NATURE AND FORM OF APOCALYPTIC

There is no agreed list of Jewish apocalyptic books, but those generally accepted as belonging to the group, or as having apocalyptic elements in them, are as follows:

1. The biblical Book of Daniel; 165 B.C.
2. I Enoch, 1–36, 37–71, 72–82, 83–90, 91–108; *c.* 164–80 B.C. (*see* ENOCH, BOOKS OF).
3. The Book of Jubilees; *c.* 150 B.C. (*see* JUBILEES, BOOK OF).
4. The Sibylline Oracles, book iii; from *c.* 150 B.C. onward (*see* SIBYLLINE ORACLES).
5. The Testaments of the Twelve Patriarchs; second half of the 2nd century B.C. but with extensive Christian redaction (*see* TWELVE PATRIARCHS, TESTAMENTS OF THE).
6. The Psalms of Solomon; *c.* 50 B.C. (*see* SOLOMON, PSALMS OF).
7. The Assumption of Moses; 4 B.C. (or perhaps A.D. 7)–A.D. 30 (*see* MOSES, ASSUMPTION OF).
8. The Martyrdom of Isaiah; A.D. 1–50 (*see* ISAIAH, ASCENSION OF).
9. II Enoch (the Book of the Secrets of Enoch); 1st century A.D. (*see* ENOCH, BOOKS OF).
10. The Life of Adam and Eve (the Apocalypse of Moses); shortly before A.D. 70.
11. The Testament of Abraham; 1st century A.D.
12. The Apocalypse of Abraham, 9–32; *c.* A.D. 70–100.
13. The Sibylline Oracles, book iv; *c.* A.D. 80.
14. II Esdras, 3–14; *c.* A.D. 90 (*see* ESDRAS, SECOND BOOK OF).
15. II Baruch (the Syriac Apocalypse of Baruch); A.D. 100–130 (*see* BARUCH APOCALYPSES).
16. The Sibylline Oracles, book v; after A.D. 100.

Apart from II Enoch and the several Sibylline Oracles, which reflect a Hellenistic background, these books probably originated in Palestine.

There has been much controversy among scholars concerning the authorship of these books, which have been ascribed to each of the main Jewish sects in turn. It is very doubtful, however, whether they belonged exclusively to any one particular party. The Judaism of the period before A.D. 70 embraced many parties and sects, among which there was much interchange of ideas and beliefs. It seems likely that there were some in all these parties, and outside them, who shared in the apocalyptic tradition. The apocalyptists do not form a sect; they represent a certain mood or temper of religious belief.

Popular Literature.—Although only one of these writings, the Book of Daniel, gained canonical authority, many others must have acquired a measure of sanctity and were highly valued. It is uncertain to what extent they may have been used in the synagogues and schools, but the indications are that they enjoyed a considerable popularity particularly in certain circles within Judaism. The ideas contained in this literature would be more widespread than the books themselves and would have a strong appeal to the Jewish people as a whole. There are indications that as late as the 3rd century A.D., in some parts of the Diaspora at any rate, apocalyptic was still highly esteemed. In the synagogue at Doura-Europus (A.D. 245) on the Euphrates there appear, prominently displayed, the figures not only of Moses and Joshua but also of Enoch and Ezra, representing the apocalyptic tradition. It is of interest to note that many fragments of an apocalyptic character were found among the writings of the Qumran covenanters, with whom, it seems certain, this kind of literature was very popular. It may well be, indeed, that some of the apocalyptic books were actually written there. The Book of Jubilees, I Enoch and certain sources of the Testaments of the Twelve Patriarchs are represented among these discoveries (*see* DEAD SEA SCROLLS).

When, in course of time, the apocalyptic books fell out of favour in Palestine they had already been translated into Greek by the Jews of the Diaspora and enjoyed an even greater popularity there. The Christians in their turn took over this literature and popularized it still more by adapting it to their own use.

Background of Persecution.—The first and greatest of the apocalyptic writings, the Book of Daniel, was written in a time of national crisis when the Jews suffered grievous persecution under Antiochus IV Epiphanes (175–163 B.C.). Those that followed continued through the troubled times of the Hasmonaeans, the Herodians, the Roman procurators and the Zealot fanatics. Not only did they reflect the unrest of the time but their teaching did much to fan the flames of revolt, particularly in the war of A.D. 66–70 and the revolt of Bar-Cochba in A.D. 132–135. Their message has rightly been called "a gospel for bad times." It did much to

encourage the faithful to continue their struggle against evil powers and to hope for the miraculous intervention of God.

Character: Esoteric.—The apocalyptic writers believed that certain divine secrets had been revealed to them which they were to record in their "hidden" books and which would enable the righteous to discern the signs of the coming End. The secrets thus disclosed are recorded in "heavenly tablets" which contain an account of "all the deeds of mankind . . . to the remotest generations" (I Enoch lxxxi, 2) and foretell the evil which is to come upon the earth (cvi, 19).

Authorship: Pseudonymous.—The pattern of this disclosure is roughly the same in all the books. They record revelations of divine secrets made known by God to certain elect individuals, ranging from Adam to Ezra, who purport to be the authors of the books. Apocalyptic is thus almost invariably pseudonymous. These revelations generally consist of an account of world history culminating in the End. For generations they have been kept secret; this disclosure now makes clear that the End is at hand.

Form: Visionary.—The form taken by this divine disclosure is usually that of dreams, visions, trances, auditions or translations in which the seer is permitted to visit heaven or hell. There the divine mysteries—past, present and future—are revealed to him, often by an angelic attendant. This literary device is common in Greek literature, but probably the apocalyptists were influenced even more by the Old Testament idea of a heavenly council presided over by God and attended by angels and sometimes by men (*cf.* I Kings xxii, 19 ff.; Job i, 6 ff.; etc.).

Language: Symbolic.—Symbolism is the language of apocalyptic. Some is derived from the Old Testament, whose metaphors and figures are adapted to a new purpose; much, however, derives from ancient mythology and from foreign sources. The pattern of presentation is largely stereotyped. Animal figures of many kinds represent men and nations; angels symbolize men; stars indicate fallen angels. Numerology too plays its part, symbolic significance being given to certain numbers which feature also in the Old Testament and in Babylonian and Persian sources.

RELATION OF APOCALYPTIC TO PROPHECY

The transition from prophecy to apocalyptic is not marked by a sudden break, and Daniel does not represent an entirely new type of literature. Apocalyptic had its beginnings in the Old Testament in such passages as Ezek. xxxviii–xxxix, Zech. xii–xiv, Joel and Isa. xxiv–xxvii. In these writings the ground was prepared and the seed sown; but in the time of Antiochus Epiphanes conditions were right for spectacular growth and in Daniel the seed came to full flower.

Apocalyptic as Fulfillment of Prophecy.—During the intertestamental period the belief was held that prophecy had ceased soon after the Babylonian exile (*cf.* I Macc. iv, 46; ix, 27; xiv, 41). The apocalyptists, however, believed that they stood in the true prophetic tradition and sought to interpret human life and destiny in the light of the prophetic revelation. As T. W. Manson pointed out, apocalyptic was really an attempt to rationalize and systematize the predictive side of prophecy. In particular, the apocalyptists proceeded to interpret and reinterpret unfulfilled prophecies in the light of their own day and of the approaching End. An example of this is Jeremiah's prediction that the captivity would last 70 years (xxv, 11; xxix, 10), which is reinterpreted by Daniel as 70 weeks of years (ix, 24) and by I Enoch as the 70 reigns of the 70 "shepherds" or angels who would shepherd Israel (lxxxix, 59 ff.). Somewhat the same method is adopted in the Book of Revelation, where the Antichrist's rule of 42 months (xi, 2; xiii, 5) is a reinterpretation of the three and a half years of persecution referred to in Daniel ("a time, two times, and half a time"; vii, 25, xii, 7).

Divine Compulsion.—Much of this literature no doubt follows a stereotyped, conventional literary pattern and has an air of artificiality about it. It would be less than fair, however, to think of the apocalyptists as mere plagiarists, woodenly reproducing what the prophets and other apocalyptists had written. They were deeply religious men with a message for their time who wrote under a sense of divine compulsion as the prophets had done before them. Behind the literary convention may be traced, in some cases at any rate, genuine experiences of inspiration (through actual dreams, visions and the like) that lie midway between the inspiration of the prophets and that of a more modern literary kind.

Literary, Not Oral.—Both prophet and apocalyptist were given a message to proclaim. But their methods were different. The prophet, for the most part, declared his message by word of mouth, which might subsequently be recorded in writing. The apocalyptist, on the other hand, remained completely hidden behind his message, which he wrote down for the faithful to read. God's command to the prophet was, "You shall speak to them this word" (Jer. xiii, 12); His command to the apocalyptist was, "Write what you see in a book" (Rev. i, 11).

Pseudonymity.—The prophets spoke in their own name a message for their own day; the apocalyptists wrote in the name of some notable man of the past a message for the time of the End. Many explanations have been given of this strange phenomenon. R. H. Charles maintained that, from the time of Ezra onward, when prophecy was believed to have ceased, the all-sufficiency of the Law made impossible the reception of fresh revelations of faith and truth unless the books containing them came under the aegis of certain great names in the past. It is doubtful, however, whether the Law was in fact regarded as all-sufficient at that time, for the prophetic canon was certainly not closed by the time of Ezra, and it is more than doubtful that pseudonymity can be explained in terms of such open deception. This charge was removed by H. H. Rowley, who suggested that the author of the Daniel stories, in the first part of that book, later wrote an account of his visions under the guise of Daniel, not with the intention of deceiving his readers but in order to reveal his identity with the author of the Daniel stories, and concludes that pseudonymity only became artificial when it was woodenly copied by imitators.

This may well be a true explanation of the origin of apocalyptic pseudonymity, but, as has been indicated above, in the case of some of these writers at least the evidence seems to suggest more than simply the following of a literary convention, indeed a genuine experience of inspiration. Not only did they want their readers to believe their revelations; they actually believed them themselves. If this is so, it would indicate that they had a deep sense of kinship with those in whose name they wrote and were convinced that they were saying the kind of thing the ancient seer would have said were he alive at that time. For the purpose of revealing the divine secrets they were essentially the same people. In support of this, F. C. Burkitt suggested that the choice of a name was not arbitrary but showed more or less the problems occupying the writer's mind. This explanation would have even greater credence if, as has been suggested, the writers were using ancient traditions long associated with those in whose names they wrote. In this case the apocalyptist would see himself as the interpreter and not simply as the author of his book.

Deterministic View of History.—The apocalyptists inherited the idea of the unity of history from the prophets (*cf.* Amos and Deutero-Isaiah) and developed it along two lines, no doubt under the influence of Zoroastrianism. First, they divided history systematically into well-defined periods—into 85 Jubilees (Assumption of Moses) or 10 "weeks" (Apocalypse of Weeks in I Enoch) or 7 parts (Testament of Abraham) or 12 parts (Apocalypse of Abraham, etc.). Second, they taught that history, thus divided, had been predetermined by God, Who recorded on the heavenly tablets its fixed orders: "What is determined shall be done" (Dan. xi, 36). The course of history from the beginning and the predetermined time of the End God had revealed to His servants, who recorded them in their books. By calculating the times and seasons and by identifying events in the scheme they could discover at what point in time they stood; almost invariably this was in the last days just before the End.

Concern With Eschatology.—The future and the world to come are the prevailing interest of apocalyptic. In some writings the prophetic idea of the Kingdom of God established on this earth persists. But generally speaking these writers despaired of the present and of this world and looked to the future and to the world to come for the fulfillment of their hopes. Already there had been

growing up in Judaism, largely under the influence of Persian thought, an eschatology described by S. Mowinckel as at once dualistic, cosmic, universalistic, transcendental and individualistic. The old idea of a kingdom on earth gives place to a supernatural kingdom in a new heaven and a new earth (I Enoch 37–71) or a spiritual kingdom in heaven (II Enoch) or a temporary earthly kingdom followed by an eternity in heaven (II Esdras and II Baruch; *cf.* Rev. xx for a similar millennial idea) in which the righteous will share through resurrection.

An important aspect of this eschatology is the Day of Final Judgment, which might be described as a development and specialization of the prophetic Day of the Lord. In the prophets judgment falls upon the living and takes the form of a great crisis in history when destruction overtakes the nations; in the apocalyptists it includes the dead and assumes a forensic character in which individual men receive their just reward. (*See* also ESCHATOLOGY; LAST JUDGMENT.)

MESSAGE OF APOCALYPTIC

Purpose and Goal of History.—Like the prophets before them, the apocalyptists saw in the working out of history a purpose and a goal. The evil in the world might lead men to despair, but the unfolding of the plan of the ages (*see* above) showed clearly the predetermined purpose of God which could not be frustrated. Nor would this purpose end with the climax of history, for "the Most High has made not one world but two" (II Esdras vii, 50). The future age of righteousness would replace the present age of ungodliness and God's purpose would at last be fulfilled. This literature, then, is a mixture of pessimism—times would become worse and worse and God would destroy this present evil world—and of optimism—out of travail and confusion God would bring in His kingdom, the goal of history.

Angels and Demons.—Persian influence is to be traced in the remarkable growth during this period of the belief in angels and demons. Angels act as God's intermediaries, are arranged in ascending orders of rank and acquire names and personalities of their own. Of particular interest is the idea that each nation has a guardian angel upon whose power and authority depend the fortunes of the peoples on earth. (A variation of this is to be found in the Book of Revelation in the angels of the churches, who, as representatives of these churches, are answerable for them to God.) The evils perpetrated against Israel by the nations are ascribed to the angels who, in the End, share the punishment of evil earthly rulers.

An early apocalyptic tradition traces this association of the angels with evil to the story recorded in Genesis vi, 1–4 which tells how the angels, later called "watchers," lust after the daughters of men (*cf.* I Enoch, Jubilees, Testaments of the Twelve Patriarchs, II Enoch). From this illicit union a brood of giants is born from whose bodies evil spirits come forth (I Enoch xv, 8 ff.) who continue their work of inciting to sin until the final judgment. This developed doctrine of angels and demons, and the notion that the present world is in the power of the prince of demons, is familiar to readers of the New Testament. (*See* also ANGEL.)

Advent of the Messiah.—The figure of the Messiah does not occupy a central place in these writings, but certain developments within this idea are of the utmost importance, especially for an understanding of the New Testament. In several apocalyptic books (Daniel; I Enoch 1–36, 91–104; Jubilees; Assumption of Moses; II Enoch) no mention is made of a Messiah. In others the traditional Davidic Messiah is presented (*e.g.*, Psalms of Solomon). In at least one writing (Testaments of the Twelve Patriarchs) hope is expressed in the coming of two Messiahs, one priestly and the other kingly; this belief seems to have been shared by the covenanters of Qumran.

But most important of all is the emergence of a transcendent type of Messiah, closely associated with a mysterious "Son of Man," who plays a significant role in certain of these writings. Of particular interest in this connection are the Similitudes of Enoch (I Enoch 37–71), in which the Son of Man is described as a pre-existent, heavenly being who stands at the head of "the elect ones," and by whom the righteous will one day be exalted to share in God's kingdom. In II Esdras this transcendent Son of Man is presented as the Messiah.

Resurrection and Life Beyond.—With the exception of two passages there is no clearly expressed belief in life after death indicated in the Old Testament. It is of considerable significance that both these passages are to be found in an apocalyptic setting and that both express this belief in terms of resurrection. The first is Isa. xxvi, 10, possibly dating from the 3rd or 4th century B.C., in which most scholars see a reference to the resurrection of the body; the second is Dan. xii, 2–3, dating from 165 B.C. This concept undergoes considerable development in the extracanonical apocalyptists and supplies a bewildering number of variations. The conviction that the righteous must be raised to share in the glories of the coming kingdom (as in Isa. xxvi, 10) was accompanied by the belief that the wicked also must be raised to receive due punishment for their sins (as in Dan. xii, 2–3). In this literature, then, for the very first time in Jewish thought, moral distinctions are made in the realm of the departed. Here, too, for the first time the departed are called "souls" or "spirits," although in the two biblical apocalypses the typical Old Testament picture of Sheol as the abode of "shades" is retained. In subsequent writings the concept of Sheol undergoes a radical change. No longer is it the eternal abode of all the departed; it has become a waiting place from which the souls of men are taken in resurrection to receive reward or punishment. Two separate compartments appear, one for the righteous and one for the wicked. These are subdivided still further to provide paradise, heaven, hell and Gehenna in addition to Sheol itself where the souls of men suffer punishment, even before the resurrection, or else await the coming judgment. The influence of these ideas on the New Testament conception of the last things is obvious, in particular on the Book of Revelation.

RELATION OF APOCALYPTIC TO JUDAISM AND CHRISTIANITY

Judaism.—It has been argued by some scholars that Jewish apocalyptic lay outside the main stream of Judaism and that, indeed, it represents a rather stagnant backwater. This contention is difficult to substantiate. It is true that it does not represent what G. F. Moore calls the "normative" Judaism of the rabbinical writings; but the indications are that during the intertestamental period at any rate it was part of the accepted Jewish tradition and represented one important aspect of its life and belief.

A comparison of the apocalyptic literature with the writings of the Qumran covenanters, for example, gives an indication of the prevalence of apocalyptic ideas during this period. Apart from the fact that several apocalyptic books are represented among the Qumran texts, the two bodies of literature are closely related not only in the beliefs expressed but even in actual words and phrases used. In particular there is a close connection in expression of messianic hopes, in belief in good and evil spirits and in ideas concerning the End—the final apocalyptic battle, the judgment to come, the reward of the righteous and the punishment of the wicked in the life beyond. Whatever their exact relationship may be, it is certain that they shared a common spiritual tradition.

This, too, can be said of the relationship between apocalyptic and orthodox Pharisaic Judaism. To both alike the Torah, for example, was central and commanded reverence as the revelation of God. Moreover, that deep ethical concern so often expressed by the rabbis is found frequently in the writings of the apocalyptists, while in such beliefs as the resurrection of the body and the advent of the Messiah there is no small measure of agreement. The influence of apocalyptic thought and even phraseology can be traced in the writings of the rabbis themselves and in the later liturgy of the synagogue.

Some time after A.D. 70, however, the apocalyptic literature became unpopular with official rabbinical Judaism and met with antipathy on the part of the rabbis. At least two reasons probably lie behind its ultimate rejection by Judaism. One is the dangerous part played by this literature, with its often belligerent messianic hopes, in rousing the people in open rebellion against Rome, which led to the downfall of Jerusalem in A.D. 70. The other was the interest now being taken in it by the Christians, who had begun

to adopt it for their own use.

Christianity.—It is not at all surprising that, almost from the beginning, the Jewish apocalyptic writings were popular with the Christians who had themselves been brought up in the Jewish faith. The teaching contained in them covering such matters as the resurrection of the dead, the Kingdom of God and the imminent return of the Messiah was very much in keeping with the church's hopes and expectations. As Greek rather than Aramaic became increasingly the language of the Christian community, these books, already popular in Greek translations among the Jews, became even more widespread, and when at last they were relinquished by Judaism they remained the secure possession of Christianity. Thus, with the exception of the canonical Book of Daniel, the tradition of apocalyptic is Christian, not Jewish. This entire body of literature, then, owes its survival to the Christian church, which has preserved the several books, in whole or in part, in many languages.

Not content with taking over the Jewish apocalypses, however, Christian writers set about interpolating them with specifically Christian teaching (as, for example, in the Sibylline Oracles) or adding to them entire new sections with a Christian content (as in the Ascension of Isaiah or the Christian additions to II Esdras). In this way they were able to claim the support of ancient traditions for their new faith.

Within the New Testament canon itself the pattern of Jewish apocalyptic is evident. This is particularly the case with the Book of Revelation (*q.v.*), by far the most significant of all the Christian apocalypses. Though a Christian writing, it draws freely on Jewish apocalyptic tradition and follows in a true line of descent from the earlier writings. Many of the marks of Jewish apocalyptic are to be found in it—fantastic imagery, symbolic language, angelic powers, the overthrow of evil, the resurrection of the dead, the final judgment, the messianic kingdom, the world to come. The chief difference lies in the person of the Messiah and the Christian interpretation given to him as the meaning and end of human history.

Quite apart from this canonical book, many other apocalypses were written in the course of the following centuries, usually in imitation of earlier Jewish works. A number of these were attributed to New Testament characters such as Peter, Paul, Thomas, John, Stephen, James, James the Less, Philip and the Virgin Mary. Not a few of the apocalyptic writings from these centuries are known to us only by name or in fragments preserved by the Church Fathers.

Three apocalypses, dating from the 2nd century A.D., may be singled out for special mention. These are the Epistle of the Apostles, the Shepherd of Hermas (*see* APOSTOLIC FATHERS) and the Apocalypse of Peter. The first is in the form of a revelation from the risen Lord and purports to be based on his speeches. The Shepherd of Hermas narrates certain allegories in the form of visions; it has a deep interest in eschatology and points to the last judgment. The Apocalypse of Peter, like the Shepherd, was widely read in Christian circles for a time and is the most important of all those named after apostles. In it the Lord, at the request of his disciples, gives signs of his second advent and of the End. Reference to the last judgment is followed by a gruesome picture of hell and the punishment of sinners according to their deeds. Visions of heaven are also given and the glories of the saints in paradise revealed. The stress in this book on the fate and future condition of individual souls had a considerable influence on later writings and especially on medieval theology.

Generally speaking, when in course of time Christian expectations of an early return of Christ faded, the apocalyptic books, both Jewish and Christian, tended to fall out of favour. The hope, however, remained, and again and again the Christian church has turned to this kind of literature for inspiration and encouragement in times of crisis and persecution.

BIBLIOGRAPHY.—Most of the Jewish apocalyptic books are to be found translated in *The Apocrypha and Pseudepigrapha of the Old Testament*, vol. ii (1913), ed. by R. H. Charles, and in several volumes of *Translations of Early Documents*, ed. by W. O. E. Oesterley and G. H. Box. R. H. Charles has published a number of larger commentaries on individual apocalypses. A convenient list of Christian apocalyptic writings is given by M. R. James in *The Apocryphal New Testament* (1924) and in *The Lost Apocrypha of the Old Testament* (1920). Informative articles by R. H. Charles appear in J. Hastings *et al.* (eds.), *Dictionary of the Bible*, vol. i, pp. 109–110 (1900) and in T. K. Cheyne and E. S. Black (eds.), *Encyclopaedia Biblica*, vol. i, col. 213–250 (1899); by H. T. Andrews in A. S. Peake (ed.), *Commentary on the Bible*, pp. 431–436 (1920); and by J. B. Frey in L. Pirot (ed.), *Supplément au dictionnaire de la Bible*, vol. i, col. 326–354 (1928).

Other books of a more general character are: Joshua Bloch, *On the Apocalyptic in Judaism* (1952); F. C. Burkitt, *Jewish and Christian Apocalypses*, Schweich lectures for 1913 (1914); R. H. Charles, *A Critical History of the Doctrine of a Future Life*, 2nd ed. (1913); R. T. Herford, *Talmud and Apocrypha* (1933); R. H. Pfeiffer, *History of New Testament Times* (1949); F. C. Porter, *The Messages of the Apocalyptical Writers* (1905); H. H. Rowley, *The Relevance of Apocalyptic* (1944); D. S. Russell, *Between the Testaments* (1960) and *The Method and Message of Jewish Apocalyptic* (1964); C. C. Torrey, *The Apocryphal Literature* (1945). (D. S. R.)

APOCRYPHA, NEW TESTAMENT, early Christian or semi-Christian writings that in form resemble the books included in the New Testament but were not admitted to the canonical collection. These are not analogous to the Old Testament Apocrypha, for most of the New Testament apocryphal literature never was regarded as acceptable by orthodox Christians; it was produced by and for schismatic or heretical groups, especially by Gnostics (*see* GNOSTICISM).

In the past the writings of the Apostolic Fathers (*q.v.*) sometimes were included among the New Testament Apocrypha, but such a classification is purely arbitrary.

Early Christian writers classified some of the apocrypha as "spurious" (Christian but noncanonical); they treated other documents as plainly heretical. In general, however, there was little dispute; the apocryphal writings were simply rejected. Among them is sometimes placed the *Testamentum Domini* ("Testament of the Lord"), but this is a 5th-century expansion of the *Apostolic Tradition* of Hippolytus (*q.v.*).

In addition to complete books or fragments of books, there are isolated sayings recorded (supposedly from oral tradition) by later writers. These sayings, whether "authentic" or not, can add nothing to our knowledge of Jesus because the canonical writings provide the only norm by means of which they can be tested.

Most of the apocryphal literature consists of (1) gospels; (2) acts or preachings or teachings of the apostles; and (3) epistles. For the Apocalypses *see* APOCALYPTIC LITERATURE.

GOSPELS

Traditions of the deeds and sayings of Jesus were circulated, both orally and in writing, along with the four gospels that came to be accepted universally. Apparently it was in the first half of the 2nd century that attempts were made to create gospels in which these materials were utilized and interpreted; usually materials from the canonical gospels also were employed. The authors of the apocryphal gospels often tried to give the impression that their works were historically and theologically reliable; in some instances they pretended that they were conveying secret doctrines that Jesus had set forth to only a few of his disciples. Under such circumstances they naturally reproduced some materials from the canonical gospels (so that Jesus would be recognizable as Jesus) and some materials from their own—often Gnostic—theology (so that Jesus would be recognizable as the revealer of their teaching). The church recognized these purposes and rejected the works.

Papyrus Fragments of Unknown Gospels.—These include:

1. Oxyrhynchus Papyrus 840 (4th–5th century), a discussion of ritual purity between Jesus and a Pharisee who is high priest. (The Oxyrhynchus papyri are a collection found at the site of the 4th-century town of Oxyrhynchus in Egypt, beginning in 1897. *See* OXYRHYNCHUS; PAPYROLOGY.)

2. Egerton Papyrus 2 (2nd century), sayings of Jesus based on the four gospels.

3. Oxyrhynchus Papyri 1, 654 and 655 (3rd century), all of which come from the Gospel of Thomas.

4. A Coptic papyrus fragment (Strasbourg 5–6) of the 5th–6th century, containing a prayer of Jesus and a discussion with the apostles.

Gospels Not Ascribed to Authors.—Among these are:

1. The "gospel" created by Marcion (*q.v.*) by removing so-called interpolations from the Gospel of Luke.

2. The Gospel of Perfection, a Gnostic work quoted once by Epiphanius (4th century).

3. The Gospel of Truth, used, according to Irenaeus (*c.* 185), by Valentinian Gnostics. This is probably the work which, found among the Coptic Gnostic writings from Nag-Hammadi, Egy., was published in 1956 by M. Malinine, H. C. Peuch and G. Quispel under the title *Evangelium Veritatis;* several pages missing in their edition were published by P. Labib in *Coptic Gnostic Papyri From the Coptic Museum in Old Cairo* (1956); *cf.* also K. Grobel, *The Gospel of Truth* (1960). The work is a mystical-homiletical treatise based not on secret traditions but on a mixture of Christian doctrine with a kind of Gnosticism that is Jewish in origin.

Gnostic Books in the Name of Jesus.—These writings are not, strictly speaking, gospels, but their content resembles that of gospels. Among them are:

1. The Coptic treatise (two versions extant) called the Sophia (Wisdom?) of Jesus Christ, a postresurrection dialogue with the disciples (a 3rd–4th century Greek fragment in Oxyrhynchus Papyrus 1081).

2. Two Books of Jeû containing secret mysteries revealed by "Jesus the Living."

3. Pistis Sophia, a 3rd–4th-century revelation of the same sort.

4. The Dialogue of the Savior, a similar document found at Nag-Hammadi.

Gospels Ascribed to Biblical Personages.—These writings include works ascribed to "the apostles," such as:

1. The Epistle of the Apostles (not really an epistle), from the middle of the 2nd century, an apocalyptic, antiheretical discourse supposedly given by Jesus after the resurrection.

2. The Gospel of the Twelve, now completely lost but mentioned by Origen.

3. Perhaps the Gospel of the Seventy.

More often, apocryphal gospels were ascribed to individual apostles. These works include books ascribed to:

4. James, especially the 2nd-century "protevangelium of James," which in a 3rd-century papyrus (Papyrus Bodmer V, edited by M. Testuz, 1958) is entitled "Genesis [birth? bringing forth?] of Mary—Revelation of James"; this work was valued by many Church Fathers because it set forth the perpetual virginity of Mary.

There is also an Apocryphon (secret book) of James from Nag-Hammadi.

5. John, especially the 2nd-century Apocryphon of John, known in one form to Irenaeus and in others to those who produced various Coptic versions of Jesus' Gnostic teaching after the resurrection.

6. Judas (Iscariot), in whose name there was a gospel that, according to Irenaeus, was used by the Gnostic Cainites (*see* CAIN).

7. Matthias, whose "traditions" were known to Clement of Alexandria.

8. Peter, supposedly author of a gospel that was rejected about 190 by Serapion, bishop of Antioch; an 8th–9th-century fragment was found at Akhmim, Egy., in 1886.

9. Philip, supposedly author of a gospel from Nag-Hammadi that contains Gnostic teaching (chiefly Valentinian).

10. Thomas (the work found at Nag-Hammadi is called the Gospel of Thomas; there is another Nag-Hammadi book called the Book of Thomas the Athlete; in addition there is an "infancy gospel" ascribed to Thomas).

Several apocryphal gospels were assigned to women. Among them were:

11. The Gospel of Eve, quoted by Epiphanius.

12. The Major and Minor Questions of Mary (Magdalene), also discussed by Epiphanius.

13. The Gospel of Mary (Magdalene), partly preserved both in Greek (Rylands Papyrus 463, early 3rd century) and in Coptic (Berlin Papyrus 8502, 5th century).

Epiphanius also describes a Gnostic parody of the Genesis of Mary (*see* number 4 above).

Gospels Ascribed to Sectarian Leaders or to Groups that Used the Books.—The existence of such gospels as those ascribed to Apelles, Bardesanes, Basilides and Cerinthus is questionable; on the other hand, Marcion and Mani certainly composed works of this kind. Among relatively early gospels used by special groups are three that reflect Jewish Christianity as it gradually came to be more sectarian:

1. The Gospel according to the Hebrews, probably written in Egypt in the 2nd century and known chiefly from quotations given by Clement of Alexandria and Jerome.

2. The gospel used by the Ebionites (*q.v.*).

3. The gospel used by the Nazarenes (*q.v.*).

The interrelations of these three gospels (if there really were three of them) have not been established. In addition, there was a gospel according to the Egyptians, now known only from fragments, that reflects its author's tendency toward Gnosticism. This work may have been used by the author of II Clement (*see* CLEMENTINE LITERATURE).

ACTS

The apocryphal Acts of the Apostles are rather different from the New Testament book of Acts (*see* ACTS OF THE APOSTLES). While the latter is concerned with the work of the Holy Spirit as the guide of the apostles in their work of proclaiming the gospel and establishing the church (though some biographical interest is not absent), the apocryphal Acts deal primarily with the miraculous and piquant adventures of individuals, and the doctrine set forth by most of them is a popular form of 2nd-century Christianity that often verges on Encratism (*i.e.*, asceticism carried to the point of heresy). Both in form and in content these Acts are close to the contemporary Hellenistic romances (*see* ROMANCE), and details in many of them seem to be borrowed from such writings. The authors of such works tried to make the story of Christian origins dramatic; usually they made it merely melodramatic. Tertullian (early 3rd century) relates that the author of the Acts of Paul was known to be a presbyter of Asia Minor; he claimed that he had written from "love of Paul," but he was deposed. Even so, these Acts were still used as an authority by Hippolytus and Origen, and it was not until the early 4th century that clear evidence shows that they were almost universally rejected.

Andrew.—Acts of Andrew were rejected by Eusebius and, according to Epiphanius, used by Gnostics. Such acts are extant in various forms, including several versions of martyrdoms of Andrew, Acts of Andrew and Matthias among the Cannibals, and Acts of Peter and Andrew.

Barnabas.—Journeys and Martyrdom of Barnabas, 5th-century acts, were written to glorify Cyprus, where Barnabas was believed to be buried, in its struggle with Antioch. The author supposedly was John Mark, described as formerly a servant of a certain Cyril, high priest of Zeus. They are partly based on the canonical book of Acts.

Bartholomew.—This Martyrdom describes the adventures and death of the apostle in India.

John.—The Acts of John (Oxyrhynchus Papyrus 850, 4th century), very close to the Hellenistic romance, probably came from Asia Minor in the 2nd century. They contain occasional semi-Gnostic touches. (*See* also JOHN, GOSPEL ACCORDING TO AND EPISTLES OF SAINT: *Literary History: Apocryphal Acts of John.*)

Matthew.—The Martyrdom of Matthew describes miracles and death of Matthew in "the land of the cannibals"; evidently Matthew is confused with Matthias (see *Andrew* above).

Paul.—These include the Acts of Paul, Acts of Paul and Thecla, and Acts and Martyrdom of Peter and Paul. The most popular of all the apocryphal Acts, those of Paul and Thecla (or of Paul alone, according to varying titles), describe the apostle's activities in Asia Minor and tell of an encounter with a lion he had previously baptized (*cf.* the story of Androcles and the lion).

Peter.—These include Acts, Martyrdom (= Acts of Peter with Simon) and Peter and Paul (see *Paul* above) (Oxyrhynchus Papyrus 849, 4th century). Close in popularity to the Acts of Paul, these were probably modeled after them. Striking parallels exist

between some of the sayings of Jesus in the Martyrdom of Peter and those in the Gospel of Thomas. This work, composed *c.* 190, contains Peter's question, "Domine, quo vadis?" and the reply of the risen Lord that he goes to Rome to be crucified (again). Acts of Peter and the Twelve have been found at Nag-Hammadi.

Philip.—The Acts of Philip relate deeds, especially miracles, of Philip in Greece, Parthia and the land of the Ophians (apparently Naassene Gnostics), and his martyrdom.

Thaddaeus.—The Acts of Thaddaeus include the story of how Thaddaeus converted Abgar, king of Edessa, and others.

Thomas.—The Acts of Thomas is a semi-Gnostic account of the oriental adventures and death of the apostle; the book includes the Gnostic "hymn of the pearl." It was used by Gnostics and Manichaeans.

EPISTLES

No fewer than five of the 49 Gnostic works found at Nag-Hammadi are in epistolary form (including an epistle of Peter to Philip), and this form was popular among authors of apocryphal books (*cf.* the Epistle of the Apostles, above). Below are considered only the letters written in the name of the apostle Paul but not admitted to the New Testament canon in the west.

Achaeans.—Such a letter, mentioned in the correspondence of Seneca with Paul (*see* below), probably never existed.

Alexandrians.—According to the Muratorian list, such a letter was forged by Marcionites. No trace of it exists.

III Corinthians.—An antiheretical letter, probably of the late 2nd century, composed largely out of the genuine epistles, along with a letter from the Corinthians to Paul.

Laodiceans.—This is found in Latin biblical manuscripts from the 6th century and later; there is also an Arabic translation from the Latin. It is intended to supply the lack of a letter from Laodicea mentioned in Col. iv, 16. (According to Marcion, the letter known as Ephesians was properly entitled Laodiceans.)

Macedonians.—This title is mentioned by Clement of Alexandria but probably refers to Philippians (Philippi is in Macedonia), from which he quotes.

Seneca.—A collection of letters, probably from the 4th century, supposed to have been exchanged by Paul and his contemporary, the philosopher-politician Seneca; first mentioned by Jerome.

In addition, there are several apocryphal letters among the writings of the Apostolic Fathers (*q.v.*) and in the Clementine literature (*q.v.*); a famous forgery is the Letter of Jesus to Abgar (*q.v.*). *See* also APOCRYPHA, OLD TESTAMENT.

(R. McQ. G.)

APOCRYPHA, OLD TESTAMENT.

The term apocrypha, the plural of the Greek neuter adjective *apocryphon* ("hidden away"), is used to designate certain religious books highly regarded by the Jews of ancient times but never included in the Hebrew canon of Scripture. In the narrowest sense it refers to a section in the King James version of the Bible (and other versions related to it) that contains those books found in the Greek and Latin translations of the Old Testament but not in the original Hebrew. In a broader sense it is used to cover not only these books but also certain other noncanonical writings from Hebrew antiquity, such as those more commonly called pseudepigrapha—books "written under a false name," most of them of an apocalyptic character.

The use of the term apocrypha is merely arbitrary and conventional, since the books ordinarily designated by it were never "hidden away," either in the sense of being literally concealed from the public or of containing esoteric teaching. The origin of the term is still a matter of dispute, but the most probable view derives it from the legend preserved in II Esdras (IV Esdras of the Vulgate), ch. xiv, which relates that when Ezra was commissioned to republish the Law in the days following the Babylonian Exile he was told that Moses on Mt. Sinai had been instructed to "hide" many of the words he received (verse 6) and that he himself was to issue publicly only a portion of the books that were dictated to him, the others to be delivered "in secret to the wise" (verses 26, 46). From this tradition of a store of books deliberately "hidden away" from public use there arose quite naturally an imprecise use of the word apocrypha to denote any books outside the familiar canon. It was in this sense that the word was introduced into Christian usage by Cyril and Jerome as a convenient name for those books they found in the Greek Old Testament (the Septuagint) but not in the Hebrew. Although these books were, for the most part, ultimately included in the Latin Vulgate, Jerome himself proposed to call them apocrypha with the connotation "uncanonical"; in later Roman Catholic usage they are called deuterocanonical but without any implication of inferior worth or authority. Jerome's usage subsequently was revived by the reformers Andreas Karlstadt and Martin Luther. Luther segregated the surplus books of the Latin canon in a separate section, which he called Apocrypha, a custom that was then imitated in the authorized versions of the reformed Church of England. The Apocrypha is an integral part of the King James version of the Bible and was always printed with it until 1827, when the British and Foreign Bible society, followed by the American Bible society and other publishers, decided to omit it in their editions.

STANDARD APOCRYPHA

The standard Apocrypha of the King James, Revised and Revised Standard versions of the English Bible consists of the following books:

1. I Esdras, a Greek translation of the canonical Book of Ezra with some important additions and variations, preceded and followed by brief portions of II Chronicles and Nehemiah (*see* ESDRAS, FIRST BOOK OF).

2. II Esdras, an apocalyptic work of the 1st century A.D. (neither of these books was included in the Septuagint or in Luther's Bible, and both appear in the Vulgate only as part of an appendix attached to the New Testament) (*see* ESDRAS, SECOND BOOK OF).

3. Tobit, a pleasant romantic story that gives interesting insight into Jewish beliefs and customs in the late pre-Christian era (*see* TOBIT, BOOK OF).

4. Judith, a nationalistic and unhistorical account of the deliverance of the people of Bethulia by the heroic conduct of a noble widow Judith (meaning "Jewess") (*see* JUDITH, BOOK OF).

5. The Rest of Esther; *i.e.*, those portions of the Book of Esther, characterized by a religious spirit missing in the Hebrew, that are found only in the Greek (*see* ESTHER, BOOK OF: *Rest of Esther*).

6. The Wisdom of Solomon, the most valuable of the apocryphal books, a philosophical work that evidences the growing *rapprochement* in Alexandria between Judaism and Hellenistic philosophy (*see* WISDOM, BOOK OF).

7. Ecclesiasticus, or The Wisdom of Jesus ben Sirach, another wisdom book which, however, remains firmly anchored in the main stream of the older Hebrew wisdom literature (the prologue makes it plain that it was composed in Hebrew; portions of the Hebrew original have been found in modern times in the Genizah at Cairo and the Dead sea caves) (*see* ECCLESIASTICUS).

8. Baruch, a pseudepigraphic work, somewhat difficult to characterize, which contains a letter purporting to have been written by Baruch in Babylon to the people of Jerusalem (i, 1–iii, 8), a hymn in praise of wisdom (iii, 9–iv, 4), and a song of comfort addressed to the people of Israel (iv, 5–v, 9); to which is appended

as a sixth chapter (in the King James, Revised and Douai versions) another pseudepigraph, the Epistle of Jeremy, a brief polemical essay on the folly of idolatry (printed as a separate book in the Revised Standard version) (*see* BARUCH, BOOK OF; JEREMY, EPISTLE OF).

9. The Song of the Three Children, Susanna and the Elders, and Bel and the Dragon, the additional items that appear in the Septuagint version of Daniel, the first being a liturgical composition placed upon the lips of the three young Hebrews who were thrown into the fiery furnace, while the other two are independent stories loosely connected with the Book of Daniel by the fact of having a common hero (*see* DANIEL, BOOK OF).

10. The Prayer of Manasses, a brief devotional composition that was never part of the Septuagint and is found in the standard Apocrypha only because the Vulgate includes it, like the two Books of Esdras, in an appendix attached to the New Testament (*see* MANASSES, PRAYER OF).

11. I Maccabees, a sober historical work describing the course of the Maccabean revolt from the time of Antiochus IV Epiphanes to the accession of John I Hyrcanus.

12. II Maccabees, a more romantic account of the same revolt from the days of Seleucus IV to Judas' victory over Nicanor (*see* MACCABEES, BOOKS OF).

These books may be classified as follows: (1) Hellenistic works, composed in Greek, presumably in Alexandria (Wisdom of Solomon and II Maccabees); (2) Palestinian works, composed in Hebrew (I Esdras, Ecclesiasticus, Baruch, Prayer of Manasses and I Maccabees); (3) Palestinian works, probably composed in Aramaic (Tobit, Rest of Esther and, possibly, II Esdras and the Additions to Daniel).

It is sometimes assumed that these works, which (with the exception of I–II Esdras and the Prayer of Manasses) are found in the Septuagint, are evidence of the existence of an Alexandrian as opposed to a Palestinian canon of Scripture. Since, however, the manuscripts of the Septuagint exhibit considerable differences among themselves and sometimes contain other books (such as III and IV Maccabees and the Psalms of Solomon), it is rather to be inferred that the distinction between canonical and noncanonical books was more fluid in Alexandria than in Jerusalem. The Palestinian canon, created by a conservative, not to say reactionary, type of Judaism, was rigidly limited to books that were unimpeachably ancient, or that were at least not patently of recent date—a standard that automatically excluded such works of indubitably Hebrew origin as Ecclesiasticus (the date and authorship of which were well known) and I Maccabees, which dealt with events of the recent past. In the freer atmosphere of Alexandria, on the other hand, while the hard core of the Hebrew canon was left inviolate, greater tolerance was shown toward other religiously valuable works, regardless of date and authorship.

OTHER APOCRYPHAL WORKS: PSEUDEPIGRAPHA

If the Hebrew canon may be regarded as the hard nucleus of Scripture and the standard Apocrypha as a surrounding layer closely attached to it, the other works, including the so-called Pseudepigrapha, may be thought of as a still further layer, centred in Scripture but much more loosely attached. None of these books ever received general recognition as part of the Bible, even though three of them are alluded to in the New Testament—Jannes and Jambres in II Tim. iii, 8, the Assumption of Moses in Jude 9, and Enoch in Jude 14 ff. No doubt many of them were highly regarded in certain more or less eccentric Jewish groups, such as the Qumran community, in whose library a number of them have appeared along with some other works previously unknown.

Certain of the additional apocrypha are known today only by name. Such, for example, are the Chronicles of John Hyrcanus mentioned in I Macc. xvi, 23 ff.; the Five Books of Jason of Cyrene, of which II Maccabees is professedly only an abridgement (II Macc. ii, 23); and the Book of Jannes and Jambres alluded to above. Others have been preserved only as selected portions of them were incorporated in other, still extant works. In this category may be mentioned the Martyrdom of Isaiah, an account of the prophet's death, preserved in the Ascension of Isaiah (*see* ISAIAH, ASCENSION OF); the Salathiel Apocalypse, included in II Esdras 3–13; and, possibly, a Book of Noah, now part of Enoch. In the general class of apocrypha are frequently listed certain quasi-historical works, such as III and IV Maccabees and the Letter of Aristeas, which are still extant.

The largest group of pseudepigrapha are apocalyptic writings such as the books of Enoch (and the Slavonic Enoch), II Baruch, the Testaments of the Twelve Patriarchs, the Psalms of Solomon, the Assumption of Moses and the Sibylline Oracles. Several fragmentary manuscripts of Enoch (though not including the important section called the Similitudes) have been found in the Dead sea caves, as have fragments of Testaments of Levi (in Aramaic) and Naphtali (in Hebrew), these latter perhaps to be accounted as sources for the Testaments of the Twelve Patriarchs rather than as parts of the completed book. (*See* APOCALYPTIC LITERATURE; BARUCH APOCALYPSES; ENOCH, BOOKS OF; MOSES, ASSUMPTION OF; SIBYLLINE ORACLES; SOLOMON, PSALMS OF; TWELVE PATRIARCHS, TESTAMENTS OF THE.)

A number of works that are legendary rather than apocalyptic also may be included among the Old Testament apocrypha: First in importance is the Book of Jubilees, a midrash on Gen. i, 1 to Ex. xiv, 31, preserved in its entirety only in Ethiopic. It was probably composed in the late 2nd century B.C. Its theme is that normative Judaism existed from the beginning of human history, and it is characterized by a division of history into jubilees, cycles of seven times seven years (*see* JUBILEES, BOOK OF). This was one of the most popular books in the community of the Dead sea scrolls, as is shown by the fact that fragments of some ten manuscripts have come to light. The popularity of the work is due in part to the peculiar, solar calendar which it (in common with I Enoch) advocates, the observance of which was evidently one of the important points of controversy between the Qumran Covenanters and the Pharisees. Since all the Dead sea fragments are in Hebrew, the view that the book was written in Aramaic becomes increasingly improbable.

Other works sometimes counted among the legendary apocrypha are a series of writings in Latin, Greek or one of the oriental church languages, apparently based on Jewish sources, that deal with the life of Adam and Eve; several late Christian versions of what seems to be an older Jewish work dealing with the story of Joseph and Asenath (in which Asenath is represented as really the daughter of Shechem and Dinah and only the foster daughter of Potipherah); and Pseudo-Philo's *Liber Antiquitatum Biblicarum*, a haggadic revision of biblical history from Adam to the death of Saul. To these should be added the *Lives of the Prophets*, a work perhaps originally written in Hebrew as early as the first century A.D., but surviving only in Greek, Latin, Syriac and Ethiopic. It purports to supplement the information given in the Bible about the more important Hebrew prophets.

APOCRYPHAL WORKS FROM QUMRAN

The discovery, beginning in 1947, in the caves near Khirbet Qumran at the northwest corner of the Dead sea, of great quantities of manuscripts and manuscript fragments that once belonged to the library of a community of Covenanters (probably to be identified with the Essenes, who are known to have lived in this vicinity) brought to light portions of Tobit (in Hebrew and Aramaic) and the Hebrew Ecclesiasticus (in a form that agrees closely with medieval Hebrew texts found by Solomon Schechter in the Cairo Genizah). As noted above, Jubilees and some form of the Testaments of the Twelve Patriarchs also are represented there.

Of greater interest, however, is the discovery of some fragments of the Damascus, or Zadokite, Document. This book, unknown until it was found in the Cairo Genizah by Schechter in 1910, was included by R. H. Charles in his edition of the Apocrypha and Pseudepigrapha and was widely studied by scholars, although its original provenance and historical significance were uncertain. The fact that fragments of it have been found in the Dead sea caves and that other Qumran literature shows marked affinity with it makes it apparent that this document was a product either

of the Qumran community or of some closely affiliated group. The document that is closest to it is the so-called Manual of Discipline, an almost complete scroll containing the rule of life by which the Qumran community was governed and upon which knowledge of its distinctive beliefs and practices is largely based. In this connection must also be mentioned a briefer document that sets forth the Rule of the Congregation "at the End of Days," when the ideal of the community was to be more perfectly realized.

A special class of literature, which scarcely falls into the category of apocrypha but should be mentioned here for the sake of completeness, is represented by the various fragments of commentaries on parts of the Old Testament—Genesis, Isaiah, Habakkuk, Micah, Nahum and Psalm 37. More strictly "apocryphal" in character are several documents for which no precise parallels are known: the War of the Sons of Light With the Sons of Darkness, the Genesis Apocryphon, the Copper scroll and the Thanksgiving Psalms (the names in all cases being modern inventions used merely for convenience of reference). The War scroll gives the plan of campaign for the last great battle of world history when the conflict between the forces of good and evil reaches its decisive climax. The idea of such a final battle appears in the Old Testament and later became one of the stock elements in Hebrew apocalyptic literature. The scroll published under the title of *A Genesis Apocryphon* (edited by N. Avigad and Y. Yadin) remained unrolled for several years because of the poor condition in which it was found and was then commonly supposed to be a lost "Book of Lamech," since the patriarch's name could be seen in the opening lines. When read, however, it turned out to be an Aramaic midrashic paraphrase of some of the early stories of Genesis. The Copper scroll acquired its name from the unusual material on which it was inscribed. Like the Genesis Apocryphon, it remained unopened for several years, but when the problem of unrolling it was finally solved by the drastic procedure of cutting it into strips, it proved to contain a list of sites in Palestine where large treasures are supposedly buried. The Thanksgiving Psalms (Hebrew, *hodayoth*) are a collection of religious lyrics, highly personal in character, which praise God for His merciful dealings with the poet, who is thought by some to be the Teacher of Righteousness, the founder of the Qumran sect. *See* also APOCRYPHA, NEW TESTAMENT; DEAD SEA SCROLLS.

BIBLIOGRAPHY.—The texts of the Qumran manuscripts (apart from the Genesis Apocryphon and the Copper scroll) are to be found in M. Burrows *et al.* (eds.), *The Dead Sea Scrolls of St. Mark's Monastery* (1950); E. L. Sukenik (ed.), *The Dead Sea Scrolls of the Hebrew University* (1955); and D. Barthélemy and J. T. Milik, *Discoveries in the Judaean Desert*, vol. i (1955). Translations of the more important of them are included in M. Burrows, *The Dead Sea Scrolls* (1955) and *More Light on the Dead Sea Scrolls* (1958), and T. H. Gaster (ed. and trans.), *The Dead Sea Scriptures in English Translation* (1956).

Introduction, translation and text for the more important standard and traditional apocrypha will be found in R. H. Charles (ed.), *The Apocrypha and Pseudepigrapha of the Old Testament in English*, 2 vol. (1913) and in the series, edited by S. Zeitlin, called *Jewish Apocryphal Literature* (1950–). *See* also C. C. Torrey, *The Apocryphal Literature* (1945). (R. C. DE.)

APOCYNACEAE, the dogbane family, a numerous group of dicotyledonous plants composed chiefly of tropical twining shrubs but including also various trees and perennial herbs, all with a milky, often poisonous juice. There are about 130 genera and 1,000–1,100 species, comparatively few of which are found in cool temperate regions. Of the species representing the family in North America, only about 6 are found as far north as New York and adjacent Canada. The best known of these are the American dogbane (*Apocynum androsaemifolium*) and the Indian hemp (*A. cannabinum*). In the British Isles the family is represented by the greater and the lesser periwinkle (*Vinca major* and *V. minor*), the latter of which has run wild in the eastern United States. Several tropical genera yield rubber (*Landlophia, Cardopinus, Funtumia, Urceola, Willoughbya,* etc.); others are sources of drugs (*Aspidosperma, Strophanthus, Alstonia, Allamanda,* etc.). Some are exceedingly poisonous, notably the ordeal tree (*Tanghinia*) of Madagascar, the manghas tree (*Cerbera*) of tropical Asia and the Bushman's poison (*Acocanthera*) of South Africa. Other widely known plants of this family are the oleander (*Nerium oleander*), the temple tree or frangipani (*Plumeria acuminata*), the crape jasmine (*Tabernaemontana coronaria*), the star jasmine (*Trachelospermum jasminoides*) and the Chilean jasmine (*Mandevilla suaveolens*). The Natal plum (*Carissa grandiflora*) and several other species produce edible fruits and many are showy ornamental plants. (*See* DOGBANE; INDIAN HEMP; OLEANDER; PERIWINKLE.)

The leaves are simple, entire and usually opposite; the flowers are regular, sympetalous, with the parts in fours or fives, and are borne either singly or clustered in cymes or panicles.

APODICTIC, a logical and philosophical term, approximately the same in meaning as "necessary" or "a priori." Aristotle used the word occasionally in the sense of "demonstratively certain" (*i.e.,* inferred from premisses that are certain). Kant classified judgments according to the kind of assertion made: in *assertoric* judgments something is asserted to be true; in *problematic* judgments something is held to be possible; while in *apodictic* judgments something is held to be necessary. On this traditional view, an apodictic judgment would take the form *A is necessarily B.* The word is now used (though somewhat rarely) in the more general and vaguer sense indicated above. (M. BK.)

APOGEE, in astronomy, that point in the orbit of a satellite, natural or artificial, which is farthest from the earth. In the case of the moon, the distance at apogee is approximately 253,000 mi.

APOLDA, a town of Germany which after the partition of the nation following World War II was located in the Erfurt district of the German Democratic Republic, is about 6 mi. N.E. of Weimar. Pop. (1959 est.) 29,621. For centuries it has been noted for bell casting and the nationally owned Apolda bell-casting works export a large part of their output. In the bell museum is an extensive collection of bells and chimes. Apolda is on the railway line from Leipzig to Weimar. Its industries include leather and knitted goods, and dye and chemical works.

Apolda, named in 1119, became a town in the 13th century. Until 1666 it belonged to the bishopric of Mainz.

APOLLINAIRE, GUILLAUME (real name WILHELM APOLLINARIS DE KOSTROWITZKI) (1880–1918), French poet who in his short life took part in all the avant-garde movements which flourished in French literary and artistic circles at the beginning of the 20th century, and who helped to direct poetry into unexplored channels.

He was born in Rome, Aug. 26, 1880, the son of a Polish *émigrée* and an Italian officer; but his origins were long kept secret, and his father did nothing for him. Left more or less to himself, he went at the age of 20 to Paris, where he led a bohemian life. Several months spent in Germany in 1901 had a profound effect on him and helped to awaken him to his poetic vocation. He fell under the spell of the Rhineland, and later recaptured the beauty of its forests and its legends in his poetry. More important, he fell in love with a young Englishwoman, Annie Playden, whom he pursued, unsuccessfully, as far as London; his romantic disappointment inspired him to write his famous "Chanson du Mal-Aimé."

After his return to Paris, Apollinaire became well known as a writer and a habitué of the cafés patronized by literary men. He met Paul Fort and Jean Moréas, became friendly with André Salmon, André Billy, Paul Jean Toulet and Léon Paul Fargue and in 1903 attempted to run an avant-garde review, *Le Festin d'Ésope.* He also made friends with some young painters who were to become famous—Maurice de Vlaminck, André Derain, Raoul Dufy and Pablo Picasso; he introduced his contemporaries to Douanier Rousseau's naïve paintings and to Negro sculpture; with Picasso, he applied himself to the task of defining the principles of a cubist aesthetic in literature as well as painting.

His first volume, *L'Enchanteur pourrissant* (1909), is a strange dialogue in poetic prose between the magician Merlin and the nymph Viviane. In the following year a collection of vivid stories, some whimsical and some wildly fantastic, appeared under the title *L'Hérésiarque et Cie* (1910). Then came *Le Bestiaire* (1911), in mannered quatrains. But his poetic masterpiece was *Alcools* (1913); in these poems he relives all his experiences and expresses them sometimes in alexandrines and regular stanzas, sometimes in

short unrhymed lines and always without punctuation.

In 1914, Apollinaire enlisted. He became a second lieutenant in the infantry, and received a head wound in 1916. Discharged, he returned to Paris and published a symbolic story, *Le Poète assassiné* (1916), and more significantly, a new collection of poems, *Calligrammes* (1918), which is dominated by images of war and his obsession with a new love affair. But on Nov. 9, 1918, two days before the Armistice, he died of Spanish influenza.

In his poetry Apollinaire made daring, even outrageous, technical experiments; his *calligrammes,* thanks to an ingenious typographical arrangement, are designs as well as poems. More generally, Apollinaire set out to create an effect of surprise or even astonishment by means of unusual verbal associations and, because of this, could be called the herald of surrealism. Yet he sometimes forgot all his modernistic principles and poured out his sufferings and his nostalgia in sincere and melodious lyrics of haunting beauty.

APOLLINARIS (APOLLINARIUS), THE YOUNGER (*c.* 310–*c.* 390), bishop of Laodicea in Syria, collaborated with his father, Apollinaris the Elder, in reproducing the Old Testament in the form of Homeric and Pindaric poetry, and the New Testament after the fashion of Platonic dialogues, when the emperor Julian had forbidden Christians to teach the classics. In his eagerness to combat Arianism, Apollinaris went so far as to deny the existence of a rational human soul in Christ's human nature, this being replaced in Him by a prevailing principle of holiness, the Logos.

It was held that the system of Apollinaris was really Docetism and the position was condemned by several synods and in particular by that of Constantinople (A.D. 381). Apollinaris had a considerable following which after his death divided into two sects, the more conservative taking its name (Vitalians) from Vitalis, bishop of Antioch, the other (Polemeans) adding the further assertion that the two natures were so blended that even the body of Christ was a fit object of adoration. The Apollinarian type of thought persisted in what was later the Monophysite school (*see* MONOPHYSITES).

Although Apollinaris was a prolific writer, scarcely anything has survived under his own name. But a number of his writings are concealed under the names of orthodox Fathers, long ascribed to Gregory Thaumaturgus. These were collected and edited by Hans Lietzmann, under the title *Apollinaris von Laodicea und seine Schule* (1905).

Apollinaris must be distinguished from the bishop of Hierapolis who bore the same name and who wrote one of the early Christian "apologies" (*c.* 170).

APOLLO, a god of manifold function who occupied the loftiest place, next to Zeus, in the Greek pantheon. Though his original nature is obscure, to Greeks of the historical period he was above all the averter of evil, presiding over religious law and expiation, who communicated to man through prophets and oracles his knowledge of the future and the will of his father Zeus. No god save his father awoke such dread and awe as he, and no god was handled with more respect by poets and mythmakers. Homer considers him the deadliest of the gods and compares his coming with the swift onrush of night (*Iliad* i, 47). Beside him the hero Diomedes, who can sneer at Aphrodite and wound Ares, is puny indeed. Homeric Hymn 3 records the fear felt even by the gods when first Apollo came among them, when only his mother Leto and Zeus himself could endure his presence. Hesiod and Pindar humanize him by including in his sphere music and the dance and by telling of his loves with mortal girls, but nowhere in their pages nor in those of the Athenian tragedians does his stature diminish. In humbler circles he was also a god of crops and herds, though his chief concern was seldom with the life of nature as such, but only as in its less regular features—the encroachment of wild animals and disease—it affected the hopes and fears of men.

This most Hellenic of all gods was of foreign origin. Even Delphi, where during the middle of the 1st millennium B.C. his cult was virtually the centre of Greek religion and its nearest approach to a Vatican, remembered him as a newcomer. Archaeological evidence suggests that Apollo came to Delphi long after the Greeks had settled there. The gods who are said to have preceded him have left particularly shadowy traces, but from their names—Ge (Earth) and Themis (Moral Order), which are Greek words, and Poseidon, a god of ancient standing among the Greeks—it seems likely that Apollo ousted Hellenic deities. Less reliable is the evidence that the older gods possessed an oracle; prophesy by inspiration, at any rate, probably came to Delphi with Apollo. In this ritual the prophetess (called Pythia) sat upon a tripod chair and delivered Apollo's message while in or immediately upon release from a state of ecstasy, a condition devoid of violence and hysteria and resembling apparently a mediumistic or visionary trance. Sometimes she spoke a verse of several lines, perhaps previously prepared by other priests, sometimes when a simple choice among answers was sufficient she drew lots. The path by which Apollo and the Pythia came to Delphi is uncertain. He had many other oracles, not only on the Greek mainland but also in Asia Minor and on the islands. One in Lycia (a region in southern Asia Minor) and another on Delos in the Aegean were well known; each claimed to be his birthplace. Homeric Hymn 3 gives Delos the honour, implying that he came thence to Delphi; the latter opinion is probably right, but Apollo can scarcely have been a Delian aboriginally, for many things link his cult there to Asia Minor. (*See* also ORACLE.)

The theory that the Greeks first met Apollo in Lycia was advanced in 1903 by Ulrich von Wilamowitz-Moellendorff and is now, with certain modifications, generally though not universally accepted. Very striking is his epithet Letoides ("son of Leto"); rarely were the Greeks called after their mothers, but the practice is common in Asia Minor and Lycia especially. No other Greek god bears a matronymic epithet (Hermes, for instance, is called "son of Maia," but always with the full descriptive form). Apollo fights against the Greeks in the *Iliad;* in the pre-Homeric tradition he and Paris killed Achilles, the greatest Greek hero. Of the other Trojan champions, Ares and Aphrodite are of foreign origin, while Artemis, who alone has roots on Greek soil, plays a quite unimportant role in the poem and doubtless owes her Trojan allegiance to the fact that she was Apollo's twin sister. The gods who fight for the Greeks, on the other hand, are all from the Greek mainland, and the division seems hardly fortuitous. If Homer depicts Apollo as a full-fledged Olympian, his alien origin was probably known to Homer's remote predecessors. Apollo's mother Leto was from Asia Minor and of little importance elsewhere; her name seems related to the Lycian word *lada* ("woman"). If Apollo was Lycian, his common epithet Lykeios is easily explained, though it can be otherwise derived. Delian hymns honouring divinities subordinate to Apollo and Artemis were attributed to the Lycian poet Olen. It is characteristic of Apollo that at certain annual periods he was not present at his shrine, and many cults believed that he had retired homeward. It is tempting to infer, from the Delians' belief that he spent his winters in Lycia, that Lycia was his original homeland, but the more general inference is safer, that the Greeks first met Apollo somewhere in Asia Minor. Such caution accords with the practice of early writers, often

THE MANSELL COLLECTION, LONDON

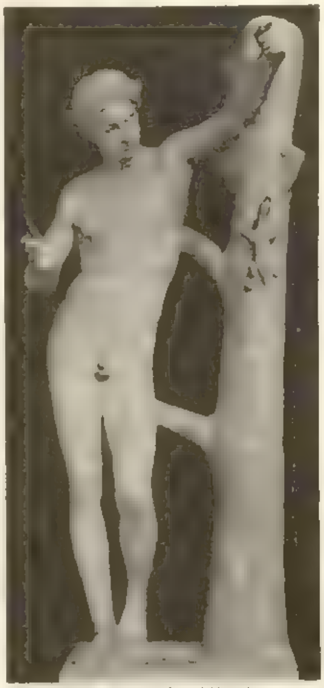
APOLLO BELVEDERE. GREEK SCULPTURE, DISCOVERED IN THE LATTER PART OF THE 15TH CENTURY; A COPY OF A BRONZE ORIGINAL. IN THE VATICAN MUSEUM

imprecise as to Lycia's exact location. Apollo may have had Hittite roots, and certain ritual features—especially the tendency for his festival to fall on the 7th day of the month—seem to derive from Babylonia. Why he and Artemis, different in function as well as geographic origin, became twins is not certainly known. Each carries a bow, and this slim similarity may have induced the Greeks to give Artemis' name to some Asiatic precursor who was Apollo's original sister; they gave her name freely to deities of widely differing natures. Several authorities say that Apollo came from or retired yearly to the land of the Hyperboreans (*q.v.*), a largely if not wholly mythical people whose name most Greeks—though not most moderns—interpreted as meaning "Beyond the North Wind." From their land, said the Delians, came the sacred relics which long ago the Hyperboreans had sent by their own ambassadors but now brought no further than their nearest neighbours, whence they passed from people to people until reaching Delos. The Hyperboreans thus left dark both the early stages of the journey and their own location. Some said that to get there one passed through the land of the one-eyed Arimaspi and the gold-guarding griffins, while Pindar held that the road lay neither on land nor sea. If Pindar is referring to the Milky Way, as has been supposed, it is hard to see how the Hyperboreans can have lived in a fixed spot beyond the north wind. Yet scholars have maintained that Apollo first came to Greece from the north, and there may in fact have been northern influences: his singing swan is a northern bird; amber, often associated with Apollo, is a northern product; some have located the Hyperboreans, and the Apollo-worshipers dwelling on the blessed isle of Helioxia as well, on the Frisian North sea coast and on Helgoland, whence amber was brought to Greece. Helgoland also is reportedly famous for its singing swans. But to give definite geographical location to lands known from myth and legend is dangerous. Apollo, furthermore, was god of music, famous for his lyre, so that a few random appearances of the singing swan in the Mediterranean may have sufficed to make it his bird. Supporters of Apollo's northern origin point to the Stepterion, a Delphic ritual commemorating, among other things, his victory over the serpent Python, whom he slew when taking over the cult; included was a procession to Delphi along a road leading from the vale of Tempe in the north. But even supposing that the procession traced the cult's original progress, it tells us nothing of the direction whence it came to Tempe itself.

Apollo's original nature is shrouded in the darkness covering the early history of his Asian homeland, but among the Greeks he was primarily the averter of evil of various sorts: moral pollution, physical illness and danger threatening herds and crops. Yet the averter may be the sender, and the first appearance of Apollo in the *Iliad* shows him shooting the arrows of the plague upon the Achaeans from his silver bow; placated, he restores health. When in the *Oedipus Rex* Apollo sends sickness to Thebes because it harbours the polluted murderer of Laius, Sophocles in giving the moral illness a physical symbol does no violence to the ordinary conception of the god. For it was Apollo who purified murderers who were morally guiltless or had made restitution; such a man was still polluted in divine eyes. Orestes in Aeschylus' *Oresteia* must go to Delphi for expiation though he killed his mother at Apollo's specific behest. Apollo himself made such restitution for the slaying of the Python.

Apollo was lawgiver to the Greek states, especially in matters requiring religious sanction; he it is, says Plato in the *Republic*, who explains to all men the institution of temples, sacrifices and other services to the deity, besides rites connected with death and the afterlife. Hence he became the symbol for law, order and moral and mental excellence; hence he became too, almost unavoidably, the paradigm of masculine beauty. Yet for all his concern with human morality, he remained essentially remote from man. Aeschylus can bring him on the stage, where he claims to speak for his father, but this is unusual; the fact that he usually confines his revelations to prophets indicates that the ordinary mortal may scarcely dare to approach him.

As a vegetation deity Apollo usually ousted or absorbed an older god, though the reason for such syncretism is not always clear. Often he turned aside the ills which threaten plant life: thus he is called Smintheus (mouse-god), Panopion (ridder of grasshoppers) and Erythibios (rust-god). In the Peloponnesus he absorbed the worship of Hyacinth (*see* HYACINTHUS), a pre-Greek vegetation god who in poetry appears as a beautiful youth beloved of and accidentally slain by Apollo. Apollo was called Hyakinthios, a word also common as a Dorian month name, and in Sparta had a festival, the Hyakinthia, which began with a gloomy sacrifice and ended with a joyous paean to Apollo. Before Apollo's day this ceremony must once have celebrated the death and revival of vegetation (hence Hyacinth's death in the myth); its significance after Apollo's intrusion is elusive. Similarly the festival of the Carneia (*q.v.*), attached to Apollo, probably originally honoured a vegetation god called Karneios or Karnos. In it a man carrying grape clusters was pursued by a group of unmarried youths, and as he ran he cried out for the city's good fortune; if he was caught, all was well. The rite resembles the modern European custom of chasing animal embodiments of the harvest spirit, but ignorance of details forbids pressing the analogy. Apollo's role in the Thargelia is somewhat better understood. Named after the first fruits, or the first bread from new wheat, it included the driving out and occasionally the killing of the *pharmakos*, a man who represented the deity but also acted as scapegoat for community guilt. Since his expulsion aimed at purification, Apollo's connection with the ritual is natural enough. Perhaps thus fortuitously did he acquire the Carneia and Hyakinthia, or a connection between expiation and fertility may through want of evidence be escaping us.



THE MANSELL COLLECTION, LONDON

APOLLO SAUROCTONUS (LIZARD KILLER), A MARBLE COPY IN THE LOUVRE OF A WORK BY PRAXITELES

Scholars have argued that Apollo's tutelary role over the flock was his original function, and have interpreted the epithet Lykeios to mean not "Lycian" but "wolf-god," as indeed it may. Unfortunately this sense of the word was popular among poets but not, apparently, among shepherds. Many other epithets, some derived from cult, support the view that Apollo's pastoral role was widespread, but the simplest course is to regard it as a particular manifestation of the averter of evil.

Through the influence of Nietzsche and Erwin Rohde the world has come to regard as fundamental to Greek religion the distinction between Apollo, the orderly, rational and shining, and Dionysus, the ecstatic, emotional and dark. The distinction is neither absurd nor particularly penetrating. To poets Apollo's epithet Phoebus signified brilliance, and, beginning probably with Aeschylus, Apollo himself stood for the sun. In the *Eumenides* he champions a rationalistic approach to ethics based upon the greater importance of the father than the mother to the well-being of family and society. Sophocles in the *Oedipus Rex* suggests that foreknowledge, Apollo's prerogative, can be acquired by the man who, thoroughly understanding human character, grasps also the moral pattern (called *dike*) whereby pollution, however unintentional, leads to disaster for the polluter, and this too is rationalistic. But to most people foreknowledge seemed to require the seer's vision or the Pythian ecstasy, which if not orgiastic was hardly rational. Rohde, aware of this difficulty, maintained that Apollo borrowed prophetic ecstasy from Dionysus' cult when Dionysus came to Delphi, but this is quite impossible. And Apollo's fundamental connection with purification and release from guilt probably had emotional and not intellectual wellsprings.

Apollo moved westward early; his temple at Cumae, built over the cave of the Sibyl, dates from the 6th century B.C., that in the Flaminian meadows at Rome from 431. The latter was dedicated for the sake of the people's health, and until the second Punic War Apollo was chiefly the warder off of pestilence with the epithet Medicus. In 212, with Hannibal on the city's doorstep, an oracle was discovered ordering the institution of the Ludi Apollinares, religious games accompanied by sacrifices, and promising Apollo's aid against the Carthaginians. Ancient scholars noted that the games, instituted for the sake of victory rather than health, marked an extension of Apollo's sphere; as did the increase in the number of his ministers, from 2, to 10, to 15. These were known finally as the *quindecemviri sacris faciundis* or Committee of Fifteen for performing the rites. Originally their chief duties involved the introduction of foreign cults and the consultation of the Sibylline books, religious documents from which remedies for various catastrophes, and eventually prophesies, were drawn. As this committee became more closely associated with Apollo in particular and bore his Delphic emblems of the laurel and tripod, the god through them approached his Delphic function of peer and religious lawgiver. But not until the Augustan age did Apollo come into his own.

As a young man Augustus had chosen Apollo as his own god, and attributed his victory over Antony and Cleopatra to Apollo's superiority over monstrous Egyptian and oriental deities, whose cults appeared to him lascivious and orgiastic. In commemoration of Actium he built the Palatine Temple of Apollo, including also Diana and Latona, whom the Romans identified with Artemis and Leto. In 17 B.C. he celebrated the Ludi Saeculares, games formerly expiatory but now devoted to the inauguration of a new era, and introduced Apollo and Diana upon equal footing with Jupiter and Juno. Horace's *Carmen Saeculare* expressed for that occasion what must have been Augustus' own vision of Apollo's nature: governor of Roman destiny; master of the sun; archer; augur; averter of pestilence; and giver of sound morals to the young. Signalizing Apollo's importance as seer and corrector of general evils, Augustus in 12 B.C. had the Sibylline books brought from their former place in the temple of Jupiter to Apollo's Palatine temple. The depth and variety of Apollo's functions in this age owed much to Greek influence, and his elevation to such great prominence goes hand in hand with Augustus' determination to Hellenize the age and, by giving it Greek ideals, to make it classic.

APOLLODORUS (called SKIAGRAPHOS, "the shadow painter"), Athenian painter, active about 430–400 B.C. Ancient sources say that he was a pioneer in the history of painting. He was the first to win fame in easel instead of wall painting. His mixtures of colours and gradation of shades improved on his predecessor Agatharchus and gave his figures the appearance of reality. His manner was called *skiagraphia*, "shadow painting," or *skenographia*, "scene painting," as was that of Agatharchus. Zeuxis is said to have followed Apollodorus toward perspective and illusionistic painting. (ME. BR.)

APOLLODORUS OF ATHENS (born *c.* 180 B.C.), Greek scholar of wide interests, is best known for his *Chronicle* of Greek history. A pupil of the scholar Aristarchus, he left Alexandria about 146 B.C. for Pergamum and eventually settled at Athens. The *Chronicle*, written in the iambic trimeters commonly used in Greek comedy, covers the period from the fall of Troy (1184 B.C.) to 144 B.C. and was later continued to 119 B.C. Apollodorus' other works include a treatise *On the Gods;* one on the Homeric *Catalogue of the Ships*, used by Strabo in his *Geography;* and critical and grammatical writings; *e.g.*, on Sophron, a writer of mimes, Epicharmus, a Sicilian writer of comedy, on etymologies, etc. The compendium to Greek mythology, called *The Library*, extant under his name, is not by him.

APOLLODORUS OF DAMASCUS (fl. 2nd century A.D.), Greek architect, was a favourite of Trajan, for whom he constructed a stone bridge over the Danube (A.D. 104–105). He also planned a gymnasium, a college, public baths, the Odeum and the Forum Trajanum within the city of Rome, and the triumphal arches at Beneventum and Ancona. The Trajan column in the centre of the Forum is the first triumphal monument of the kind. On the accession of Hadrian, Apollodorus was banished and, shortly afterward, being charged with imaginary crimes, put to death (Dio Cassius, lxix, 4). He wrote a treatise on siege engines, which was dedicated to Hadrian.

APOLLONIA, the name of more than 30 cities of antiquity two of which were especially important.

APOLLONIA BY EPIDAMNUS, on the right bank of the Aous river in Illyria on a site 5 mi. W. of the modern town Fier in the prefecture of Berat in Albania, was founded by the Corinthians and Corcyraeans in the 6th century or earlier. It soon became prosperous as the most convenient link between Brundisium and northern Greece and later as one of the starting points of the Via Egnatia. Toward the close of the Roman republic it was a seat of literature and philosophy. Augustus was being educated there when the death of Caesar called him to Rome. It seems to have declined from the 5th century A.D. and few ruins remain.

APOLLONIA PONTICA OR ANTHEA on the Thracian coast of the Black sea (now Sozopol in the Burgas province of Bulgaria), was colonized by Milesians and Phocaeans at the end of the 7th century B.C.; it became famous for its colossal statue of Apollo by Calamis.

APOLLONIUS (called DYSCOLUS, "the Crabbed") (2nd century A.D.), Greek grammarian, was the founder of scientific grammar. His life was passed at Alexandria during the reigns of the emperors Hadrian and Antoninus Pius. Priscian, the Latin grammarian, styled him *grammaticorum princeps* ("prince of grammarians") and used his work as the basis for his own. Four of his works are extant: *On Syntax*, and three smaller treatises, on *Pronouns*, *Conjunctions* and *Adverbs*.

See R. Schneider and G. Uhlig, *Grammatici Graeci* (1878–1910); A. E. Egger, *Apollonius Dyscole* (1854).

APOLLONIUS OF PERGA (PERGAEUS), Greek geometer of the Alexandrian school, was probably born about 25 years later than Archimedes; *i.e.*, about 261 B.C. He flourished in the reigns of Ptolemy Euergetes and Ptolemy Philopator (247–205 B.C.). His treatise on *Conics* gained him the title of the Great Geometer, and is that by which his fame has been transmitted to modern times. Most of his other treatises were lost, although their titles and a general indication of their contents were passed on by later writers, especially Pappus. After the *Conics* in eight books had been written in a first edition, Apollonius brought out a second edition, considerably revised as regards books i–ii.

The degree of originality of the *Conics* can best be judged from Apollonius' own prefaces. That he made the fullest use of his predecessors' works, such as Euclid's four books on conics, is clear from his allusions to Euclid, Conon and Nicoteles. Books i–iv form an "elementary introduction," *i.e.*, contain the essential principles; the rest are specialized investigations in particular directions. For books i–iv he claimed only that the generation of the curves and their fundamental properties in book i are worked out more fully and generally than they were in earlier treatises, and that a number of theorems in book iii and the greater part of book iv are new. The generality of treatment is indeed remarkable; he gives as the fundamental property of all the conics the equivalent of the Cartesian equation referred to oblique axes (consisting of a diameter and the tangent at its extremity) while the principal axes appear only as a particular case after he has shown that the property of the conic can be expressed in the same form with reference to any new diameter and the tangent at its extremity. On the basis of the form of the fundamental property (expressed in the terminology of the "application of areas")

Apollonius introduced the names parabola, ellipse, hyperbola. Books v–vii are clearly original. Apollonius' genius takes its highest flight in book v, where he treats of normals as minimum and maximum straight lines drawn from given points to the curve (independently of tangent properties), discusses how many normals can be drawn from particular points, finds their feet by construction, and gives propositions determining the centre of curvature at any point and leading at once to the Cartesian equation of the evolute of any conic.

The other six treatises of Apollonius (each in two books) were concerned with cutting off a ratio; cutting off an area; determinate section; tangencies; inclinations; plane loci. An Arabic version of the first was found toward the end of the 17th century in the Bodleian library by Edward Bernard, who began a translation of it; Halley finished it and published it with a restoration of the second (1706). A restoration of the third was given by Robert Simson, *Opera quaedam reliqua* (1776).

Tangencies embraced the following general problem: Given three things (points, straight lines or circles) in position, to describe a circle passing through the given points, and touching the given straight lines or circles. The most difficult case, and the most interesting historically, is when the three given things are circles. This problem, which is sometimes known as the Apollonian problem, was proposed by François Vieta in the 16th century to Adrianus Romanus, who gave a solution by means of a hyperbola. Vieta himself solved it by elementary methods and restored the whole treatise of Apollonius in *Apollonius Gallus* (1600); an interesting account of the problem given by J. W. Camerer in *Apollonii Pergaei de tactionibus quae supersunt, ac maxime Lemmata Pappi in hos Libros, cum Observationibus, etc.* (1795). A restoration of the fifth was given by Samuel Horsley (1770), and one of the sixth by Robert Simson (1749).

Other works of Apollonius referred to by ancient writers included (1) *On the Burning-Mirror*, where the focal properties of the parabola probably found a place; (2) *On the Cylindrical Helix* (mentioned by Proclus); (3) a comparison of the dodecahedron and the icosahedron inscribed in the same sphere; (4) a work in which were included Apollonius' criticisms and suggestions for the improvement of Euclid's *Elements*; (5) a work in which, according to Eutocius, he showed how to find closer limits for the value of π than the $3\frac{1}{7}$ and $3\frac{10}{71}$ of Archimedes; (6) an arithmetical work on a system of expressing large numbers and showing how to multiply such large numbers; (7) extensions of the theory of irrationals expounded in Euclid, book x (*see* PAPPUS OF ALEXANDRIA).

Lastly, from references in Ptolemy's *Almagest* it is known that Appollonius investigated eccentric and epicyclic motion and their equivalence. Of particular interest was his determination of the points where a planet appears stationary.

BIBLIOGRAPHY.—The editions of all the Conics include, besides Edmund Halley's monumental edition of all seven Books (1710), Commandinus' Latin translation (1566), and Barrow's edition (1675) of the first four Books, and J. L. Heiberg's definitive text of the same Books, with Eutocius' commentary, etc. (1891–93); and an edition in modern notation, with introduction, etc., by T. L. Heath (1896). *See* also O. Neugebauer, "Apollonius-Studien," *Quellen u. Studien zur Geschichte der Math.*, ser. B, vol. 2, pp. 215–253 (1932).

(T. L. H.; O. E. N.)

APOLLONIUS OF RHODES (b. *c.* 295 B.C.), Greek poet and grammarian, was the author of the *Argonautica*. A native of Alexandria or possibly Naucratis, he was known as *Rhodius* because of his residence in Rhodes. The two lives contained in the Laurentian manuscript of the *Argonautica* say that Apollonius was a pupil of Callimachus (so too the Suda lexicon); that he gave a recitation of the *Argonautica* at Alexandria; and that when this proved a failure he retired to Rhodes. The first life adds the detail that the poet was still an adolescent when this happened, though it had previously said that he turned late to writing poetry. Both lives say that the *Argonautica* was well received in Rhodes and the second records a report that Apollonius returned to Alexandria and was appointed chief librarian. The Suda lexicon makes him succeed Eratosthenes in this post. But in a list of Alexandrian librarians on a late 2nd-century A.D. papyrus (Oxyrhynchus Papyrus 1241) Apollonius succeeds Zenodotus and precedes Eratosthenes.

If this evidence is accepted it may be conjectured that Apollonius became librarian *c.* 260 and continued as such until *c.* 247, when he fell out of favour under the new king, Ptolemy Euergetes, and retired to Rhodes. The date and place of his death are unknown. He had a famous quarrel with Callimachus, apparently caused by differences about poetic ideals, especially the length and form of a poem, by plagiarism on Apollonius' side and also by Apollonius' being officially Callimachus' superior since the latter was never librarian. Besides the *Argonautica*, an epic in four books on the voyage of the Argonauts, Apollonius wrote epigrams and poems on the foundations (*Ktiseis*) of cities. These are lost except for a few fragments and one epigram, preserved in the Palatine anthology (11.275), attacking Callimachus. As a grammarian, Apollonius is credited with a work "against Zenodotus" and commentaries on several Greek poets.

The *Argonautica* merits more praise than the critics Quintilian and Longinus allow. Apollonius adapted the language of Homer to the needs of a romantic epic with considerable success and in book iii, which recounts Medea's love for Jason, he shows a capacity for sympathetic analysis not found in earlier Greek literature. Virgil in *Aeneid*, iv, owes much to him. As the learned scholia to the poem show, Apollonius had read widely in the literature of the Argonautic legend, and books i, ii and iv are overloaded with erudition, but even here Apollonius often holds the reader by his fresh handling of old episodes, his suggestive similes and his admirable descriptions of nature.

(E. A. B.)

APOLLONIUS OF TRALLES (in Caria, Asia Minor), a Greek sculptor, who flourished in the 2nd century B.C. With his brother Tauriscus he executed the marble group known as the "Farnese Bull," representing Zethus and Amphion tying the revengeful Dirce to the horns of a wild bull.

APOLLONIUS OF TYANA (1st century A.D.), a Neo-Pythagorean sage whose celebrity is due entirely to the biography of him written by the rhetorician Philostratus (*q.v.*), was born at Tyana in Cappadocia somewhere about the beginning of the Christian era and survived into the reign of the Roman emperor Nerva. The biography by Philostratus, which is the only full account of him, was written *c.* A.D. 200 at the request of the empress Julia Domna, second wife of Septimius Severus, and is a highly romantic and extremely untrustworthy work in which Apollonius appears as a wandering ascetic and wonder-worker; it is impossible to ascertain what facts lie behind the accounts of his wide-ranging journeys (including a visit to India) and miraculous exploits. The memoirs of his disciple Damis, on which Philostratus claimed to base his account, are almost certainly a work of fiction. The work of Philostratus had a great success and led to a certain amount of religious veneration for Apollonius among the devout pagans of the later Roman empire. Caracalla built a shrine to him, and Alexander Severus put a statue of him in his private chapel along with those of Abraham, Orpheus and Christ. The anti-Christian writer Hierocles of Nicomedia paralleled his miracles with those of Christ, and it is possible that Philostratus himself and Julia Domna intended the *Life of Apollonius* as a sort of pagan gospel to counteract the effect of the Christian. If so, the attempt had little success.

Halliday, *Folklore Studies* (1924).

(A. H. AG.)

APOLLONIUS OF TYRE, a Latin prose romance which may be assumed to derive from a Greek original now lost. Be-

sides certain features of vocabulary, the social and topographical context of the story is Greek, while the theme and treatment place it inside the tradition of the Greek romances. Characteristic is the motif of separated lovers and the varied trials which beset them until, faithful throughout, they are reunited in a scene of mutual recognition. The story opens with a preliminary scene in which Apollonius by solving a riddle discloses that the king of Antioch is cohabiting incestuously with his daughter. Apollonius escapes the king's fury by making his way first to Tarsus and then to Cyrene, where he marries the daughter of King Archistrates. On the return journey to Tyre Apollonius' wife supposedly dies in giving birth to a daughter. She is placed in a chest, thrown overboard and washed up at Ephesus. A local doctor revives her and she becomes a priestess in the temple of Diana. Apollonius leaves his daughter in the care of foster parents and retires to Egypt. Years later the foster mother plots to kill the girl and she is saved only by the intervention of pirates, but a worse fate awaits her when she is sold to a brothel in Mytilene. In the meanwhile Apollonius, supposing his daughter as well as his wife is dead, makes a chance visit to Mytilene. To his joy he finds her alive and rescues her, still a virgin despite seemingly inevitable circumstances. His happiness is complete when in response to the promptings of a dream he proceeds to Ephesus and has his wife restored to him.

The introductory episode dealing with the king of Antioch seems to stand outside the main structure of the story and is possibly an interpolation from another source. Such was its impact, however, that the whole romance was later categorized by its character. To Chaucer the story was a tale "horrible . . . for to rede," and Gower chose it as an illustration of the seventh deadly sin in the *Confessio Amantis*.

Other features are indisputable interpolations by the Latin author, notably the inclusion of some of Symphosius' riddles, echoes from Virgil and various Christian touches.

The date of composition may be approximately fixed. The Greek original presumably derives, like the novels of Xenophon of Ephesus and other Greek romancers, from Asia Minor of the 3rd century A.D. The Latin composition must lie somewhere between the date of Symphosius (4th to 5th centuries) and a 6th-century reference to the tale by Venantius Fortunatus (*Miscellanea*, book vi, ch. x, lines 5–6, in J. P. Migne, *Patrologia Latina*, vol. 88, 1850).

Few adventure stories have had such long and widespread popularity in European literature. The survival of numerous Latin manuscripts testifies to its appeal in the middle ages. A metrical version was included in Godfrey of Viterbo's *Pantheon* in the 12th century; the prose version was further popularized by its incorporation into the 14th-century collection of tales, the *Gesta Romanorum;* and vernacular translations were made in the medieval period and continued into modern times. There exist versions in English, German, Dutch, Swedish, Danish, French, Spanish, Italian, Portuguese, Russian, Polish, Hungarian and modern Greek. The history of its treatment in England proves it to be the story with the longest tradition in the English language. An Anglo-Saxon translation (the first vernacular translation) was made in the 10th century. The more noteworthy of the later versions are John Gower's verse narrative, Lawrence Twine's novel *The Patterne of Painefull Adventures* (1576; reprinted 1607) and Shakespeare's *Pericles*, which was entered in the Stationer's Register in 1608. Despite the change in the hero's name, Shakespeare's play preserves the main outline of the story as originally conceived.

BIBLIOGRAPHY.—The Latin version was edited on the basis of the earliest manuscript (a Florentine manuscript of the 9th or 10th century) by A. Riese, *Historia Apollonii Regis Tyri*, 2nd ed. (1893). The versions of Godfrey of Viterbo and of the *Gesta Romanorum* were ed. by S. Singer in *Apollonius von Tyrus* (1895). For the Anglo-Saxon version see *The Old English Apollonius of Tyre*, ed. by P. Goolden (1958) and J. Raith, *Die alt-und mittelenglischen Apollonius-Bruchstücke: Studien und Texte zur englischen Philologie* (1956), which also includes the text of a 14th-century metrical version by "the vicar of Wimborne." For detailed study of the story's history *see* E. Klebs, *Die Erzählung von Apollonius aus Tyrus* (1899) and S. Singer's edition.

(PE. G.)

APOLLOS, an Alexandrian Jew converted to Christianity at Ephesus in the mid-1st century. According to Acts xviii, 24–28 he was concerned with Old Testament interpretation and perhaps had been a disciple of John the Baptist. After his conversion he delivered mission sermons in the Jewish synagogue, though he "knew only the baptism of John." The account that follows in Acts seems to suggest that Apollos was unaware of the significance of baptism "in the name of the Lord Jesus" and its relation to the gift of the Holy Spirit; though "instructed in the way of the Lord" he only later understood that the Messiah was Jesus. At a later point he went to the Christian church of Corinth, which the apostle Paul had "planted"; Apollos "watered" it, but in such a way as to permit the rise of partisan strife (I Cor. iii, 6; i, 10–12). Later he returned to Ephesus (I Cor. xvi, 12; *cf.* Tit. iii, 13). Apollos is significant as an example of the unclear line between Judaism and Christianity in the minds of some, at least, of the early converts. It is possible though not provable that he wrote the Epistle to the Hebrews. (R. McQ. G.)

APOLOGISTS, EARLY CHRISTIAN, the title conventionally assigned to a group of writers, chiefly in the 2nd century, who attempted to provide, at first in Greek but later in Latin, semiphilosophical defenses of Christianity and criticisms of Greco-Roman culture. Many of their writings were addressed to such Roman emperors as Antoninus Pius (138–161) and Marcus Aurelius (161–180), and it is probable that they were actually sent to government secretaries who were empowered either to accept or to reject them. Under these circumstances, some of the apologies assumed the form of briefs written to defend Christians against the accusations current in the 2nd century, especially the charges that their religion was novel or godless or expressed in immoral cultic practices. The apologists usually tried to prove the antiquity of their religion by treating it as the fulfillment of Old Testament prophecy; they argued that their opponents were really godless, since they worshiped the gods of mythology; and they insisted upon the philosophical nature of their own faith as well as its high ethical teaching. They did not intend to present a complete picture of Christianity, especially since they were arguing largely on grounds chosen by their opponents. From such writings as the *Homily on the Passover* by the apologist Melito of Sardis it can be seen that his Christian faith is not fully expressed in the extant fragments of his apology.

Origin and Nature of the Apologetic Movement.—The apologetic movement began not in Christianity but in Hellenistic Judaism, where Philo of Alexandria not only interpreted Judaism in philosophical terms but also wrote treatises (now lost) explicitly apologetic. Late in the 1st century of the Christian era Flavius Josephus was concerned more with history than with philosophy and tried to correlate biblical history with that recorded by non-Jewish writers. Both kinds of correlation are reflected in Christian apologies, though the first Christian to use Philo's writings was Clement of Alexandria, the first to use Josephus was Theophilus (*q.v.*) of Antioch. In other words, the primary influence of Hellenistic Judaism on the apologists was that of a movement of thought, not of individual writers; the apologists generally took over methods, not conclusions. To such an influence was due the apologists' emphasis on the doctrine of creation, on the importance of the Old Testament and on the work of the Logos in creation and revelation. It should be added that their work was facilitated by the situation of contemporary philosophy, in which previous dogmatic acceptance of traditional schoolteaching was being supplanted by an eclecticism that often venerated ancient oriental wisdom and sought to be justified by it. Platonism and Stoicism tended to be combined, and Skepticism, by undermining older epistemologies, opened the way for acceptance of teaching based on revelation. Finally, within New Testament Christianity itself could be found at least intimations of apologetic. Examples exist in the first two chapters of Paul's letter to the Romans and in the Areopagus address in Acts xvii. The fact that parallels to these passages can be found both in Greek and in Jewish literature shows clearly that bridges were being built between the church and the world.

The most important apologists were those in the 2nd century.

In addition to adopting Hellenistic Jewish methods, they made use of traditional materials provided in Greco-Roman education. The most obvious examples of such materials are to be found in the anthologies of poetry and philosophical opinions used in schools. In these anthologies, theological and ethical doctrines were illustrated by short excerpts from tragic and comic poets, often revealing the discord present in their views; similarly the ideas of various philosophers were briefly stated in relation to various topics. The conclusion, probably intended by the anthologists, was easy to draw: poets and philosophers alike disagreed among themselves. The apologists then proceeded to claim that truth was known only by revelation—the revelation expressed in the Old Testament and fulfilled in Jesus Christ. (The fact that such apologists as Tatian, Theophilus and Minucius Felix do not name Jesus or Christ is due to their desire to argue on their opponents' grounds.)

In addition, the apologists relied upon the doctrine of the Logos, or rational principle governing the world, to explain the existence of a general revelation that had produced some general idea of truth. According to Justin, this Logos was present, though inadequately, in Heraclitus, Socrates and even in Musonius, the Stoic contemporary of St. Paul; it had become incarnate in Jesus Christ. On the negative side, the existence of paganism was due to demons, who in the apologists' view (derived from late Judaism) were fallen angels. Both the doctrine of a universal Logos and that of subordinate supernatural beings were familiar conceptions in 2nd-century thought; the picture of the work of the Logos that Theophilus draws is strikingly parallel to what the rhetorician Aelius Aristides says of the generation and activity of Athena. And several apologists were impressed by the parallel between the life and death of Socrates and the life and death of Jesus, though they did not forget to insist upon the greater significance of the latter.

All of them had read at least some of the works of Plato, especially the *Timaeus,* in which there is a mythological description of the origin of the universe. In their view Plato had been given a partial revelation of the doctrine of creation, but the doctrine of creation was superior to Plato's because it affirmed the transcendence of God in relation to the world. This doctrine occupies an important place in their thought because it is related to the omnipotence of God and supports the doctrine of resurrection, on which they also insisted, usually defending it by analogies from nature.

It has been argued that Justin, at least, developed a "theology of history" to which Celsus replied, but it is at least doubtful that Justin had such a theology in mind, except insofar as the idea of prophecy and fulfillment points toward it. Most of the apologists found the Incarnation difficult to correlate with their apologetic. This does not mean that they failed to believe in the Incarnation (Tatian speaks once of "the God who suffered"); it only means that on the grounds they had accepted from their opponents they found it easier to speak of the generation of the Logos before or at creation.

Early Apologists.—*Quadratus.*—The earliest-known Christian apology exists only in a short fragment preserved by the church historian Eusebius (*Church History,* iv, 3, 1–2). This comes from an apology addressed to the emperor Hadrian about 125 by Quadratus of Athens, perhaps bishop there. Quadratus insists upon the reality of the healing miracles of Jesus in contrast to those ascribed to someone else, perhaps Hadrian himself. The fragment is not extensive enough to determine exactly how its author developed his apology.

Aristides.—A little later comes the apology of Aristides. In its Syriac version (from a manuscript of the 17th century) it begins with a definition of God apparently Stoic in origin and then shows, in a rather naïve way, how various religions have fallen short of it; it ends with a brief statement about the Christian revelation. It appears that much of Aristides' work is based on an earlier Jewish apology; unfortunately, it also appears that at some point in its transmission it has suffered a good deal of interpolation and revision. The Syriac version is rather different from the Greek paraphrase, which is embedded in the medieval romance *Barlaam and Josaphat* (*q.v.*). As a witness to early Christian apologetic, the apology of Aristides cannot be employed with complete confidence.

Justin Martyr.—The most significant of the early apologists was St. Justin Martyr (*q.v.*), who turned from Platonism to Christianity after his complacency was upset by the constancy of Christian martyrs, and his elementary Platonism was shattered by Christian arguments that were ultimately Aristotelian. He could no longer believe in the innate immortality of the soul or in its transmigration. As a Christian teacher he addressed to the emperor Antoninus Pius, about 150, a treatise that included a defense of Christian morality, a proof (largely based on the Old Testament) of the truth of the Christian revelation and a description of Christian worship (to show that it was not immoral). Perhaps a decade later Justin prepared a briefer work that makes more extensive use of philosophical arguments.

It appears that both works were intended for delivery to the imperial secretariat; they are genuine apologies. Politically they had little result, though it must be recalled that there were very few Christian martyrdoms in the reign of Antoninus Pius. Under Antoninus' successor, Marcus Aurelius, Justin was executed at Rome about 165, as we learn from the authentic Acts of his martyrdom. In later times he was remembered as the only Christian "philosopher" of the 2nd century, and writings composed between the 3rd century and the 6th were ascribed to him. These later writings replaced his genuine apologies, which along with his *Dialogue* with the Hellenistic Jew Trypho survive only in a manuscript copied in 1364. It is possible, but not very likely, that the fragments on the resurrection ascribed to him by John of Damascus are actually his; the mode of argument is unlike anything in the apologies or the *Dialogue.*

As for the other writings ascribed to Justin, both the *Oration* to the Greeks and the treatise *On Monarchy* (or "divine unity") contain nothing specifically Christian and seem to come from Hellenistic Judaism; the *Cohortatio* seems to reflect the religious situation of the 3rd century; the epistle *To Diognetus* is certainly not his (*see* APOSTOLIC FATHERS); and other documents set forth the Antiochene theology of the 5th century and later. The *Expositio rectae fidei* was written not by Justin but by Theodoret (*q.v.*).

Tatian.—Justin frequently wrote on the grounds of an eclectic philosophy that combined Platonic with Stoic insights; like other eclectics, he could state that "whatever has been said well by anyone is ours." His pupil Tatian (*q.v.*), trained in rhetoric rather than philosophy, reacted violently from his master's attitude, perhaps because it had resulted only in martyrdom, and probably in 177 produced his militant *Address to the Greeks,* in which he bitterly attacked almost every aspect of Greco-Roman culture, including philosophy, medicine, art and history. By the time he wrote, Tatian had probably already left the church in order to establish his own rigourist school. In the *Address* he referred to his treatise *On Animals,* in which he had explained that apart from the divine spark man was nothing but an animal. This doctrine is characteristic of Gnosticism (*q.v.*).

Apollinaris, Melito and Athenagoras.—Though Tatian's attitude toward culture was later adopted by the Latin apologist and theologian Tertullian (*q.v.*), who also left the church, in his time the other orthodox apologists shared a much more conciliatory viewpoint. The fragments of Apollinaris of Hierapolis and Melito (*q.v.*) of Sardis, about 175–176, are clearly pro-Roman. The former drew the emperor's attention to a miraculous storm that saved a Roman army in 174 and claimed that it was due to the prayers of Christian soldiers. The latter argued that since Christianity had arisen at the same time as the Roman empire and had been persecuted only by tyrannical emperors, it should be recognized as the religion of the state.

The occasion for the writings of both apologists was provided by a revolt against Marcus Aurelius, which, though crushed soon after it took place in 175, led to government efforts to ensure domestic tranquility and to attacks, at least local, upon Christians as potentially subversive. A little later, as persecution developed, Athenagoras (*q.v.*) of Athens produced his *Embassy* (177) in order to deny that Christians were either godless or

immoral. In relation to the Christian worship of God, Athenagoras provided a semiphilosophical account of the doctrine of the Trinity. His loyalist attitude is reflected in the statement that the rule of Marcus Aurelius and his son Commodus is analogous to that of God the Father and his Son. (The treatise *On the Resurrection* later transmitted with the *Embassy* is possibly not by Athenagoras since it seems to be directed against the doctrine of Origen.)

Theophilus.—The last of the early Greek apologists, Theophilus of Antioch (*see* THEOPHILUS, SAINT), stands between anti-Greek and pro-Greek views. Much less conciliatory than Justin or his own immediate predecessors, Theophilus still insists that Christians are loyal to the emperor and, while he vigorously attacks Greek philosophers, poets and historians, he goes no farther than did the Skeptics, whose arguments he used.

Anti-Christian: Celsus.—From the situation of crisis between 175 and 180 there remains one important document, almost entire, which represents the anti-Christian camp. This is the *True Discourse* produced by the Middle Platonist Celsus (*q.v.*) about 178. Known only from quotations provided by Origen in his refutation of 248, the work of Celsus shows how Christianity looked to an intelligent but highly unsympathetic critic. He first assumes the role of a Jew (or, in other words, uses Jewish sources) in order to question the historical reliability and the theological significance of the story of Jesus; then he attacks the principal Christian doctrines on grounds largely philosophical in nature. His work ends with a denunciation of the Christians for their failure to support the Roman emperor and army against barbarism. In it is found an attempt to treat Christianity as a modern version of ancient errors; like the apologist Justin (whose writings he may have known), Celsus claims that whatever is true is his.

Later Apologists.—The apologetic movement did not, of course, come to an end in the 2nd century. The impression that it did is due to the fact that while later theologians wrote apologetic works these were usually less significant than their more strictly theological writings. As examples may be mentioned the *Protrepticus* by Clement of Alexandria (*see* CLEMENT), the important reply to Celsus composed by Origen (*q.v.*), the *Praeparatio evangelica* of Eusebius of Caesarea, and the various answers offered to the anti-Christian Neoplatonists Porphyry and Julian during the 4th century.

In the latter half of the 2nd century Christian apologies were written in Latin, beginning either with the *Octavius*, composed by a certain Marcus Minucius Felix, with much use of Cicero's writings, at an uncertain date, or with Tertullian's *Ad nationes* and *Apologeticus* in 197. Tertullian's work is especially important because, while he often used the writings of his Greek predecessors, he assimilated their materials for his own purpose and created works that possess a literary distinction not found earlier. In addition, two important Latin apologies of the early 4th century exist, the *Adversus nationes* by Arnobius (*q.v.*) and the *Divinae institutiones* by Lactantius Firmianus (*q.v.*). The former is a mordant critique of pagan religion by a half-educated Christian; the latter, an elaborate philosophical analysis of pagan culture by a Christian rhetorician. The Latin apologetic movement culminated in the *City of God* by St. Augustine early in the 5th century.

In later times, under different circumstances, apologetic writings were still produced; mention need be made only of the *Proslogium* of St. Anselm (*q.v.*) and the *Summa contra gentiles* of St. Thomas Aquinas (*q.v.*). In modern times the need to present the Christian religion to a non-Christian world has led to a revival of concern for apologetics and thus to increased interest in the early apologists.

Transmission of Their Works.—After the period in which the apologists wrote, most of their writings were allowed to perish, partly because of the different political situation after the church was recognized by the Roman state and partly because of the different theological situation after the Council of Nicaea. The church realized that the Logos theology of the apologists seemed to favour the thought of the Arians (*see* ARIANISM). The few early manuscripts of their works that have survived owe their existence to Byzantine scholars; for example, in 914 Arethas, bishop of Caesarea in Cappadocia and vigorous student of classical literature, had a collection of early apologies copied for his library. Many of the later manuscripts were copied at the time when the Council of Trent was discussing the nature of tradition. The genuine writings of the apologists were virtually unknown, however, either in the east or in the west until the 16th century. The first apologetic work to be translated into Latin, the treatise *On the Resurrection* ascribed to Athenagoras, was published at Paris in 1498, but his genuine *Embassy to the Greeks* appeared there only in 1557. The genuine apologies of Tatian and Theophilus were published at Zurich in 1546. The first edition of the works of Justin Martyr in Greek (Paris, 1551) consisted largely of works wrongly attributed to him. After the 16th century the only significant discovery in this field was the publication of the apology of Aristides, from a Syriac version, in 1889. A few papyrus fragments have contributed almost nothing new.

Modern Criticism.—In the 19th and early 20th centuries the apologists, and especially Justin, often have been attacked by critics opposed to philosophical theology. Hans Lietzmann, for example, found Justin essentially confused, since on the one hand he maintained "a philosophical religion which clothes Greek ideas and conceptions in a loose Biblical garment, and which in the end issues in man's self-redemption ethically conceived," and on the other, "the unreasoned faith of the church in which words of Jesus, sacramental mysticism, and church life combine to form an active unity" (*The Founding of the Church Universal*, London; [1950] p. 185, Lutterworth Press). The key words here are "philosophical religion" and "unreasoned faith"; none of the apologists would have found this contrast meaningful. The apologists were attempting to create a synthesis; they were not altogether successful, but the ability of a modern historian to take the synthesis apart does not prove either (1) that synthesis is impossible or (2) that theirs was entirely inadequate.

APOMORPHINE is prepared from morphine by the abstraction of one molecule of water. It lacks the narcotic properties of morphine, its chief action being on the vomiting centre in the brain. As an emetic, it is administered hypodermically. It should not be used indiscriminately since even therapeutic doses may exert a profound depressant effect. *See* also MORPHINE.

APOPHOROMETER. This apparatus is used for the identification of minerals by means of sublimation. It consists of an electrically heated platinum ribbon, on which the substance under examination is spread, enclosed between two watch glasses. The whole may, if necessary, be placed in a vacuum or surrounded by an inert gas, thus avoiding the oxidizing or reducing effects of the flame used in tests with the ordinary blowpipe.

APOPHYLLITE, a hydrous calcium and potassium silcate mineral, always occurs as distinct crystals which belong to the tetragonal system. The form is either a square prism terminated by the basal planes, or an acute pyramid. A prominent feature

of the mineral is its perfect basal cleavage, on which the lustre is markedly pearly, presenting, in white crystals, somewhat the appearance of the eye of a boiled fish; hence the old name fisheye stone, or ichthyophthalmite, for the mineral. On other surfaces the lustre is distinctively vitreous.

Apophyllite is a mineral of secondary origin, commonly occurring in cavities in basalt and other lava rocks. It is often found in association with zeolites, which it resembles, but is not classed with them because it contains no aluminum. Magnificent groups of greenish and colourless tabular crystals of apophyllite, the crystals several inches across, were found with flesh-red stilbite in the Deccan traps of the Western Ghats, near Bombay, during the construction of the Great Indian Peninsular railway.

Groups of crystals of a beautiful pink colour have been found in the silver veins of Andreasberg in the Harz and of Guanajuato, Mex. Crystals also have been found in Iceland and Nova Scotia and in New Jersey, Pennsylvania, Michigan and California.

The formula for apophyllite is $KCa_4FSi_4O_{10}.8H_2O$. Its hardness is 4.5 to 5 on Mohs' scale and its specific gravity is 2.3 to 2.4. (L. J. S.; C. S. H.)

A POSTERIORI: *see* A Priori and A Posteriori.

APOSTLE. The term apostle, which means "person sent," is generally understood as applying specifically to the 12 most intimate disciples of Jesus, in fact as synonymous with "the Twelve." In Luke vi, 13 it is stated that Jesus chose 12 from his disciples "whom he named apostles." And in Mark vi, 30 the Twelve are quite casually named apostles when mention is made of their return from the mission of preaching repentance and of healing the sick on which Jesus had sent them. The full list of the Twelve is given with some variation in Mark iii, Matt. x and Luke vi: Peter, James and John the sons of Zebedee, Andrew, Philip, Bartholomew, Matthew, Thomas, James the son of Alphaeus, Thaddaeus or Judas the son of James, Simon the Cananaean (or Cananaian) or the Zealot and Judas Iscariot. For information about the individual apostles, *see* the separate articles on each of them. This article is concerned solely with the status and function of the apostles as a body.

Argument rages among scholars as to whether or not these New Testament references to "apostle" represent the first appearance of the idea in Jewish literature. Whatever may be the date of the emergence of the word *shaliach* (Hebrew equivalent of the Greek *apostolos*), the function of official messenger must often have been employed in Jewish government circles. On important business important emissaries must have been dispatched, some of whom may well have acquired the status of plenipotentiary. That Jesus followed some such precedent is at least likely.

The Twelve Apostles.—Thus, though it would be too much to say that among the Jews of the time of Jesus there was a regular office of apostle, the function at least was recognized: it had its own associated rights and privileges, and it was a simple and natural thing for Jesus to make use of it. The unusual steps that Jesus took were to make the number of his apostles 12, perhaps symbolic of the kingdom of heaven as including all 12 tribes of a restored Israel (*cf.* Matt. xix, 28; Luke xxii, 30; Rev. xxi, 10–14), and to make their function permanent, at least in the sense of giving them pre-eminence among the disciples. Even so it is to be noticed that the name apostle is used of the Twelve only once each by Mark and Matthew in connection with their actual mission, and by Luke three times referring to the mission and on three other occasions. John does not use the term *apostolos* except in xiii, 16, meaning "messenger," but he does use the cognate verb in reference to the mission of Jesus by the Father (xx, 21).

The privileges of the Twelve were to be in continual attendance on their master and to be the recipients of his special teaching and training. Once at least they were sent on a special mission, two by two in what appears to have been "apostolic" fashion, to announce the imminence of the Messianic kingdom (Mark vi; *cf.* Matt. x; Luke ix). Three of them, Peter, James and John, formed an inner circle who alone were permitted to witness such events as the raising of Jairus' daughter (Mark v, 37; Luke viii, 51), the Transfiguration (Mark ix; Matt. xvii; Luke ix) and the agony in the garden of Gethsemane (Mark xiv, 33; Matt. xxvi, 37). One of these, Peter, was recognized as their spokesman and leader and received the special promise of the keys of the kingdom of heaven (Matt. xvi, 19).

Special importance seems to have been attached to the number 12. When a gap had been left by the defection and death of the traitor Judas Iscariot, immediate steps were taken to fill it by the election of Matthias (Acts i). It is to members of this band of 12 that the word apostle is applied 24 times out of the 26 occurrences of it in Acts. Surprisingly, on the other two occasions (xiv, 4, 14) it is applied quite casually and without explanation to Paul and Barnabas.

Other Apostles.—Paul himself provides plenty of evidence that the scope of the title was wide enough to admit far more than the Twelve (*cf.* especially "Then to the twelve . . . then to all the apostles"; I Cor. xv, 5–7). He himself regularly claimed the title of apostle (*e.g.*, "Paul, an apostle of Jesus Christ by the will of God," II Cor. i, 1; Eph. i, 1; Col. i, 1; II Tim. i, 1), apparently on the ground that he had seen the Lord and received a commission directly from him. This appears to agree with the condition in Acts that a newly appointed apostle should be capable of giving eyewitness testimony to the Lord's resurrection (Acts i, 21, 22; *cf.* I Cor. ix, 1). In Rom. xvi, 7 it is at least suggested that Junias and Andronicus were reckoned among the apostles, and in Gal. i, 19 so is James "the Lord's brother."

The bearers of the title were now sufficiently numerous to have invited imitation by some who certainly had no right to it. In II Cor. xi, 13 Paul speaks of "false apostles [*pseudapostoloi*], deceitful workmen, disguising themselves as apostles of Christ." He perhaps speaks the more bitterly as he had experienced some difficulty in establishing his own claim. The passage suggests both that it was still held in high honour and that the distinctive mark of being "sent" by authority was not so clearly distinguishable as it had been in the case of the original Twelve. There appear to have been "signs" by which an apostle might be known, as for instance witness of the resurrection (Acts i, 21, 22), commissions from Christ himself (Luke vi, 13; Gal. i, 1), miracles (Acts ii, 43; *cf.* Heb. ii, 4) and possibly also inspiration (John xvi, 13). But such signs can hardly have been obvious after the first generation.

Tantalizingly little is known about the second grade of "apostles." The most satisfactory explanation is offered by A. Richardson, who draws a sharp distinction between those who had received their commission directly from the Lord, such as the Twelve, and those who were emissaries of the local churches.

Apostolic Office and Function.—It has become customary to speak of "apostolic men," the term being used as a kind of bridge between the Twelve and the later episcopal government of the church. That administration was a function of the apostles seems clear from the position accorded to them in the New Testament after the resurrection of Jesus Christ. It is notoriously difficult in reading the New Testament to distinguish between office and function. It is probable that the lists of ministerial gifts in such passages as I Cor. xii, 28 and Eph. iv, 11 have in view function rather than office; but the fact that the apostles are mentioned first suggests that they are regarded as the highest rank in the church's ministry, or, as some would put it, the rank from which all the ministry flows. Certainly the general picture presented in the New Testament makes the apostles appear as the leaders both in evangelization and in administration. Indeed it would seem almost inevitable that they should exercise authority at least in the churches of their own foundation. It is clear from the epistles of John as well as from those of Paul that that authority sometimes was challenged (*cf.* III John, 9), but the very vehemence of the riposte shows how unnatural the challenge was held to be.

Apostles After the New Testament Period.—That apostles continued to exist even after the period covered by the New Testament is clear from early Christian writers. In the *Didachē*, an enigmatic document of the 2nd century, apostles seem to be coupled with wandering prophets, about whose bona fides one cannot always be certain (*cf.* the doubtful reference in the epistle

to Diognetus, ii, 1; xii, 9). On the other hand Clement of Rome (*c.* A.D. 96), arguing the case for an official succession of ministers in his letter to the Corinthians, distinguishes clearly between the apostles and those "distinguished men" whom they appointed to succeed them and to hand on the succession again to others. Ignatius of Antioch (*c.* A.D. 115) strikes an unusual note by comparing the authority of the bishops to that of the Father and the Son, while the authority of the priesthood is compared with that of the apostles. However, by the middle of the 5th century Theodoret in his commentary on the Pauline Epistles states quite bluntly that "those who are now called bishops were formerly called apostles."

It looks therefore as if the term apostle originally given in Christian circles to the Twelve, and then achieving a wider connotation (much as the pioneer missionary of a country is still called the "apostle" of that country), later became used of the chief administrative ecclesiastical officer of a district before finally reverting to its original significance. (*See* EPISCOPACY and MINISTRY, CHRISTIAN.)

Rudolf Bultmann, however, radically changes the order of development. He holds that the looser application of the term "apostle" to all missionaries came first and was narrowed down to the Twelve in the interests of a desire to establish the theory of apostolic succession. This appears to be an anachronism. The Twelve were in great esteem from the beginning, and the gospels faithfully reflect the situation. There is no need to call in a special motive for the emphasis placed upon them in the gospel record beyond the desire to make it clear that in fact Jesus did treat them so. The recognition that the Twelve were apostles par excellence meant that they were the chosen delegates of Christ but did not preclude the possibility of the use of the term for other people on other occasions. It might be employed (*e.g.*, by Paul) to designate delegates to certain churches or the delegates of local churches to one another. By the end of the 2nd century, as in the writings of Irenaeus, the desire to prove an "apostolic" succession both of office and of doctrine against the Gnostic heresy threw the term into strong relief. But there would have been no value in appealing to apostolic precedent if it had not been firmly rooted in the tradition that the apostles had from the beginning played a leading role in the life of the church.

Legends About the Twelve Apostles.—As Paul had made missionary journeys and brought people far afield into the Christian fold, it was later assumed that the other apostles must have done the same, although there is no mention of it in the Bible. Legends relate that each went to a different territory in which he successfully evangelized the local inhabitants, usually by miraculous means. It was further believed that each apostle was responsible for one of the 12 clauses or articles in the "apostles' creed," which in fact has no direct connection with the apostles (*see* CREED). Nor were the apostles the authors of the "apostolic constitutions" (*see* CONSTITUTIONS, APOSTOLIC). When the 12 apostles are represented in art, the traitor Judas is generally omitted and Paul takes his place.

APOSTOLIC FATHERS, the title given to a group of Greek Christian writers who belonged to the second or third generation after the Apostles, with whom tradition associated them (Clement and Hermas with Peter and Paul; Barnabas with Paul; Ignatius, Polycarp and Papias with John). At first these writers were called "apostolic men" (Apostolici); the name Apostolic Fathers was first applied to early 2nd-century writers in the 6th century, after the conception of the authority of the Fathers had been developed. It did not pass into common use until the 17th century. Since that time it has been applied not only to the writers mentioned but also to the authors of a diverse group of writings that, as ordinarily printed, includes the *Teaching of the Apostles* or *Didache*, first published in 1883; the 2nd- or 3rd-century apology entitled *To Diognetus;* and the late 2nd-century *Martyrdom of Polycarp*. The group is thus very heterogenous. It included letters (one by Clement of Rome, seven by Ignatius of Antioch, one or two by Polycarp of Smyrna, one from Asiatic churches describing Polycarp's death), an apocalyptic writing with appendices (Hermas), a document dealing with church order (the *Didache*), exegetical treatises (Barnabas, fragments of Papias), a sermon (II Clement) and an apology (*To Diognetus; see* APOLOGISTS, EARLY CHRISTIAN). Not everything in the group comes from the early 2nd century, and not everything in it is equally valuable theologically; but taken as a whole the writings of the Apostolic Fathers are more valuable historically than any other Christian literature outside the New Testament. They provide a bridge between it and the more fully developed Christianity of the late 2nd century.

To a remarkable extent the writings of the Apostolic Fathers have come to light only in relatively recent times. First Clement, discovered in the Codex Alexandrinus of the Greek Bible, was published at Oxford in 1633, but a complete text of it and of II Clement was not found until 1875. The genuine letters of Ignatius, painstakingly restored by use of a medieval Latin translation by Archbishop Ussher in 1644, were first published from a Greek manuscript in 1646 at Amsterdam. The first edition of the *Epistle of Barnabas*, printed by Ussher in 1644, was destroyed by fire, and the first real publication was therefore given by Dom Luc d'Achery at Paris in 1645. Hermas was published in Latin by Lefèvre d'Étaples at Paris in 1513, but in Greek it first appeared in 1857. The letter to Diognetus appeared in 1592, when (as in the manuscript that contained it) it was assigned to the apologist Justin. The *Martyrdom of Polycarp* was first printed in 1689. Before this work of discovery and publication took place, there was a long period in which writings wrongly ascribed to the Apostolic Fathers supplanted their genuine writings. During and after their recovery, scholars tended to value their primitive teaching too highly, but subsequently a more balanced appraisal was made. Their value lies in their reflection of the beginnings of Christian life and thought.

Clement.—The oldest of the Apostolic Fathers is almost certainly Clement, who toward the end of the 1st century wrote in the name of the Roman Church to the Church of Corinth in order to urge its dissident members to return to peace and apostolic order. (*See* CLEMENT: *St. Clement I.*) His letters were regarded as scripture by many Christians of the 3rd and 4th centuries, and by some even later. The principal subjects discussed in I Clement are as follows: (1) the troubles at Corinth explained as due to jealousy and envy, with examples from the Old Testament and from the martyrdoms of Peter and Paul (1–6); (2) the need for repentance, leading to the harmony evident in the creation (7–20); (3) the importance of resurrection (21–32); (4) the necessity of good works in relation to the high priest Jesus Christ, in whose army we serve (33–38); (5) the apostolic succession (30–45); (6) Paul and the need for reconciliation and love (46–50); (7) examples showing the need for humility and obedience (51–58); (8) the need to pray for the elect (59–61); (9) summary on the inspiration of Clement and his messengers to Corinth (62–65). Each of these sections is ended with a doxology. With it, in our manuscripts, was transmitted a homily known as II Clement, probably written at Rome in the period between 125 and 140. Its genuineness, questioned by Eusebius and Jerome, was upheld in the 5th and 6th centuries by Monophysites, who believed that it anticipated their theology when it began with the words, "Brothers, we must think of Jesus Christ as of God."

Ignatius.—Another early Apostolic Father was Ignatius, bishop of Antioch early in the 2nd century, who on his way to martyrdom at Rome wrote seven letters: five to churches in Asia Minor (at Ephesus, Magnesia, Tralles, Philadelphia and Smyrna), one to Polycarp of Smyrna and one to the Roman Church. In these he opposed Judastic and/or Docetic heresy and made a plea for Christian unity, which he based primarily on the unity of the monarchical episcopate. In the 4th century (or perhaps later) his letters suf-

fered interpolation, and six more were added by someone who found Ignatian theology hard to reconcile with the conclusions of the council of Nicaea (or of Chalcedon). The Monophysites, again, found his authentic letters attractive, especially because he was fond of the expression "my God, Jesus Christ," and in this situation neo-Chalcedonians tended to use the inauthentic version instead. It was this version that Lefèvre d'Étaples first published, in Latin, in 1498. Ignatius' vivid Syrian rhetoric and his yearning for martyrdom have sometimes impelled scholars to regard him as somewhat neurotic and to discount the validity of his testimony to the primitive episcopate. His insistence upon its importance has been treated as due to idiosyncrasy. On the other hand, it would appear that, while Ignatius' ideas were not shared by all his Christian contemporaries, his witness for the state of the church should not be discounted too markedly. (*See* also IGNATIUS, SAINT.)

Polycarp.—From Ignatius' younger contemporary Polycarp one letter exists which seems to speak at one point of Ignatius' death as past and, at another, of it as future; the letter also denounces a heresy that may be that of Marcion, later than Ignatius' time. These apparent contradictions have led many scholars to suppose that they are two letters rather than one. It is also possible, though uncertain, that like Ignatius' letters that of Polycarp has undergone later revision. The Monophysites, who were quite careful in citing authorities, provided quotations from Polycarp that do not exactly correspond with the existing text (much of which is available in a late Latin translation). (*See* also POLYCARP, SAINT.)

Hermas.—Either toward the beginning of the 2nd century or somewhat later a certain Hermas, according to later tradition brother of Pius, bishop of Rome, produced a book known as the *Shepherd* (from the guise of the angel who appeared to him). It contains a series of five visions to which Hermas later added 12 moral "commandments" and ten "parables." His basic purpose was to teach that postbaptismal sin was not unforgivable; a certain "day of repentance" would soon come, though sins committed after that time could not be forgiven. Hermas represents a kind of Jewish Christianity (also reflected in II Clement) that seems to have flourished at Rome during the period. His work, regarded as scripture by many writers in the century after his time, gradually lost its influence, though it is contained in the Codex Sinaiticus of the Greek Bible and is found in many Egyptian papyrus fragments of various dates. It was translated into Latin and several oriental languages.

Barnabas.—The so-called *Epistle of Barnabas* is really an exegetical treatise on the use of the Old Testament, which in the author's view cannot be understood by Jews; its significance can be understood only by those who read it and search for "types" or prefigurations of Jesus. Its author is not content with types but often goes into the purest of allegorizations. At the end of his work he sets forth the "two ways" of light and darkness (ch. 18–19). His work, regarded as scriptural at Alexandria, was not so highly regarded elsewhere; and, though it is included in the Codex Sinaiticus, few Christians continued to read it.

Papias.—The fragments of the *Exegeses of the Dominical Oracles*, a work written by Polycarp's contemporary Papias, bishop of Hierapolis in Phrygia, were preserved chiefly by Irenaeus and Eusebius; the latter commented on the Jewish apocalypticism that undoubtedly resulted in the neglect of Papias' work, though he also preserved some rather obscure remarks of Papias about the church's gospels. (*See* also PAPIAS.)

Others.—In the latter decades of the 2nd century the *Martyrdom of Polycarp* was composed; this, along with the roughly contemporary *Martyrdom of Justin*, is the oldest authentic account of an early Christian martyr's death. Unfortunately the form in which it is presented in extant Greek manuscripts (the oldest of which comes from the 10th century) is rather different from that provided by the lengthy extracts found in Eusebius; and it is possible, if not probable, that it has undergone interpolation. In Eusebius' quotations are not found the elaborate comparison of the death of Polycarp with that of Christ which is given in the fuller version.

The epistle *To Diognetus* consists partly (ch. 1–10) of an apology for Christianity not unlike that of Theophilus of Antioch (*q.v.*) and partly of a liturgical sermon (11–12) in the style of Melito of Sardis or Hippolytus of Rome. The association of this document with the Apostolic Fathers must be regarded as simply a mistake.

Finally, the *Didache*, composed either at the end of the 1st century or toward the end of the 2nd, is not the product of an Apostolic Father but reflects the liturgy and order of a church possibly in Egypt but more probably in Syria. Its importance lies in its primitive Jewish-Christian catechetical materials (ch. 1–6; some paralleled in Pseudo-Barnabas), in its rather enigmatic description of baptism and Eucharist (7–10) and in its regulations to govern the conduct of peripatetic apostles and prophets (who are beginning to be supplanted by bishops and deacons; 11–15). The book ends with a picture of the return of Christ (16). The basic problem in regard to the *Didache* is whether it describes a real situation of the 1st century or, consciously or unconsciously, archaizes its picture from the standpoint of some later time. Treated as canonical by a few early writers, its materials were appropriated by the authors of the 3rd-century *Didascalia* and the 4th-century *Apostolic Constitutions* (*see* CONSTITUTIONS, APOSTOLIC), and, except in isolated Egyptian communities, it dropped out of use.

Significance.—The very heterogeneity of the Apostolic Fathers, in the form and the content of their writings, provides a valuable indication of the condition of Christianity immediately after, and to some extent contemporary with, the writing of the New Testament. They show how the Pauline epistles were being interpreted (I Clement, Ignatius, Polycarp); the earlier ones seem to reflect a time when the sayings of Jesus, not written gospels containing them, were regarded as authoritative, though it is not always certain that written gospels were not being used. They reflect the development of ecclesiastical authority. Clement of Rome speaks in the name of the Roman Church and, insisting upon the importance of the apostolic succession of presbyters (not altogether clearly differentiated from bishops), gives instructions to the church at Corinth. Ignatius of Antioch shows the existence of a threefold ministry of bishops, presbyters and deacons in Asia Minor and in Syria. Polycarp of Smyrna gives instructions to the presbyters of the nearby church of Philippi. The *Didache* speaks of the development of the ministry, and Hermas reflects a similar situation. Both Ignatius and the *Didache* clearly present baptism and the Eucharist as central elements of Christian life, while all these writers insist upon the importance of Christian morality.

It has been argued that their writings represent a significant decline from the Christianity of the apostolic age, especially in relation to the Pauline doctrine of grace. In reply to this claim it may be said that (1) they did not necessarily express the full range of their religion in the documents that have been preserved, and (2) the kind of doctrine of grace to be found in the major Pauline epistles is not the only emphasis tenable within Christianity. Under various circumstances various aspects of the doctrine may need to be stressed. According to the tradition of the church, and perhaps already in the letter of Polycarp, the thought of Paul himself is adequately represented not in his major epistles alone but in the Pastoral Epistles (*q.v.*) as well. In relation to apostolic Christianity, the Apostolic Fathers are important because they constitute the earliest witnesses both to New Testament scripture and to tradition. They show the New Testament church alive and flourishing in a new age, though the extent to which all of them fully represent Christian teaching in their times remains open to question; on the basis of the available evidence the question probably cannot be answered. Toward the end of the 2nd century Irenaeus (*q.v.*) made use of Clement, Ignatius, Polycarp, Papias and Hermas; he obviously regarded them as witnesses to the apostolic tradition; as a hearer of Polycarp he may well have been capable of judging whether or not they correctly represented the Christian teaching of their day.

APOSTOLICI, a name given to various Christian sects that sought to re-establish the life and discipline of the primitive church by a literal observance of the precepts of continence and poverty. The earliest Apostolici (known also as Apotactici and Renuntiatores) appeared in Asia Minor in the 4th and 5th centuries. In their origins, they are probably to be connected with the Encratites. They renounced private property and condemned marriage as impure.

The name of Apostolici also has been given to certain groups of Latin heretics of the 12th century. This movement seems to have arisen from a heretical current that entered Italy and France from the east during the 11th century. Its development was favoured by the wealth and worldliness of the western church at that time. In the course of the 12th century its Neo-Manichaean ideas (*see* MANICHAEISM) were diffused in various centres of southern and northern France, whence it passed into Flanders and the Rhineland. These groups had in common the condemnation of marriage, of the eating of meat and of infant baptism, as well as itinerant preaching, harsh criticism of the church and denial of priestly power.

In the second half of the 13th century appeared in Italy the Apostolic Brethren. This sect, whose origins are to be connected with the penitential and mystic fermentation associated with the ideas of Joachim of Fiore (*q.v.*) and with exalted Franciscanism, was founded about 1260 by Gerard Segarelli, an uncultured workman of Parma, with the idea of restoring what he conceived to be the apostolic way of life. In time he gathered a considerable number of followers who lived as wandering preachers of repentance, without vows but in absolute poverty. Segarelli's increasingly eccentric ways and the diffusion of his followers into several countries led Pope Honorius IV to order them in 1286 to adhere to an already recognized rule. The order refused to submit, and its members were marked as heretics. In 1290 Nicholas IV issued a new bull against them. A time of persecution followed. Four were burned in 1294, and Segarelli, as a relapsed heretic, went to the stake at Parma in 1300.

This persecution embittered their opposition, and under Fra Dolcino, who now took the leadership, the sect became larger, openly antisacerdotal and heterodox. Dolcino was an apocalyptic enthusiast of great gifts and eloquence, who declared in several epistles that the third Joachimite age began with Segarelli and attributed to himself a Messianic role in the establishment of a new and purer church. When a crusade was summoned against him, Dolcino entrenched himself in the mountains around Vercelli, and it was not until 1307 that the sectaries were definitely overcome and Dolcino burned. Traces of the sect remained in northern Italy, France and Spain until the middle of the 14th century.

In later times the doctrines of the various Apostolici were approached most closely by some sects of the Anabaptists (*q.v.*). (C. H. Lo.)

APOSTOLIC SUCCESSION, the doctrine according to which the bishops represent a direct, uninterrupted line of descent from the Apostles, from whom they derive certain special powers; chief among the latter are the power to ordain priests and to teach and rule over the clergy and laity of their diocese. *See* EPISCOPACY; MINISTRY, CHRISTIAN.

APOTHECARY. During the middle ages the application of the term apothecary became restricted to those who prepared and sold drugs, and it is still used in that sense in the United States, Scotland and on the European continent. In England, however, the apothecary became a general medical practitioner. (X.)

United States.—Among the earliest English and continental European colonists in America were apothecaries who had been trained in the old world. They brought with them the practices and customs of their respective countries and endeavoured to practise their art in colonial America.

Uniformity in the practice of pharmacy began to develop as the colonies became more populous and means of communication and travel improved. In addition, many drugs indigenous to America were added to the armamentarium of the apothecary. At the time of the Revolutionary War the activities of the apothecaries were so well established that an office of apothecary general was created for the army by the Continental Congress. The appointee, Andrew Craigie, served on the general staff of the army under Gen. George Washington. The guild of apothecaries organized the first college of pharmacy in Philadelphia in 1821. This school enjoyed continuous operation thereafter. William Procter was appointed to the chair of pharmacy in 1846 and distinguished himself as a teacher, investigator and organizer.

As a medical enterprise the first United States *Pharmacopoeia* was published in 1820. In 1852 the American Pharmaceutical association was organized, and pharmacists soon took an active part in the revisions of the *Pharmacopoeia*. The Food and Drugs act of 1906 made the *Pharmacopoeia* and its companion volume, the *National Formulary* published by the American Pharmaceutical association, the national standards for drugs. The colonial apothecaries guild evolved through the decades into an organized U.S. pharmacy. Nationally it came to be represented by the American Pharmaceutical association, National Association of Retail Druggists, American Association of Colleges of Pharmacy, American Drug Manufacturers association and numerous other associations representing the various facets of the profession. (J. C. K.)

England.—From early records it is apparent that the different branches of the medical profession were not regularly distinguished in England till the 16th century, when separate duties were assigned to them and peculiar privileges were granted to each. In 1518 the physicians of London were incorporated, and the Company of Barber-Surgeons, incorporated originally in 1461 but without disciplinary powers, was reincorporated in 1540 and given these powers. But, independently of the physicians and surgeons, there were a great number of irregular practitioners, who were more or less molested by their legitimate rivals, and it became necessary to pass an act in 1543 for their protection and toleration. As many of these practitioners kept shops for the sale of medicines, the term "apothecary" was used to show their calling.

In 1617 the Society of Apothecaries was founded by James I. The status of apothecaries underwent gradual consolidation and they acquired additional powers until in 1815 the society by act of parliament was given powers of examination and granting of licences to practise medicine. Armed with these powers the society insisted on courses of medical study in candidates for its licence to practise. In common with all other licensing bodies, the curriculum it imposes and the examinations it conducts are subject to scrutiny and approval by the General Medical council.

The Society of Apothecaries is governed by a master, 2 wardens and 21 assistants. The members are divided into three grades, yeomanry or freeman, the livery and the court. The hall of the society, situated in Black Friars lane, London, and covering about

three-quarters of an acre, was acquired in 1632. It was destroyed by the Great Fire, but was rebuilt about ten years later, and enlarged in 1786. This is the only property possessed by the society. In 1673 the society established a botanic and physic garden at Chelsea, and in 1722 Sir Hans Sloane (*q.v.*), who had become the ground owner, gave it to the society on the condition of its presenting annually to the Royal society 50 dried specimens of plants till the number should reach 2,000. This condition was fulfilled in 1774.

Because of the heavy cost of maintenance the "physic garden" was handed over in 1902, with the consent of the Charity commissioners, to a committee of management, to be maintained in the interests of botanical study and research. *See* also PHARMACOLOGY; PHARMACOPOEIA; PHARMACY.

APOTHEOSIS, literally "deification" (Gr. *apotheoun*, "to make a god," "to deify"). The term properly implies a clear polytheistic conception of gods in contrast with men, while it recognizes that some men cross the dividing line. It is characteristic of polytheism to blur that line in several ways. Thus the ancient Greek religion was especially disposed to belief in heroes and demigods. Founders of cities, and even of colonies, received worship; the former are, generally speaking, mythical personages and, in strictness, heroes. But the worship after death of historical persons, such as Brasidas, or worship of the living as true deities, as Lysander and Philip II of Macedonia, occurred sporadically even before the conquests of Alexander the Great brought Greek life into contact with oriental traditions. It was inevitable, too, that ancient monarchies should enlist polytheistic conceptions of divine or half-divine men in support of the dynasties. Whatever part vanity or the flattery of courtiers may have played with others, or with Alexander, it is significant that the dynasties of the Seleucids (*q.v.*) and Ptolemies (*q.v.*), Alexander's successors, claimed divine honours of some sort. Theocritus hails Ptolemy Philadelphus as a demigod and speaks of his father as seated among the gods along with Alexander. Ancestor worship, or reverence for the dead, was another factor, as was also, of course, mere sycophancy.

The Romans, up to the end of the republic, had accepted only one official apotheosis, the god Quirinus, whatever his original meaning, having been identified with Romulus. But the emperor Augustus carried on the tradition of ancient statecraft by having Julius Caesar recognized as a god, the first of a new class of deities proper. The tradition was steadily followed and was extended to some women of the imperial family and even to imperial favourites. Worship of an emperor during his lifetime, except as the worship of his genius, was in general confined to the provinces. Apotheosis, after his death, being in the hands of the senate, did not at once cease, even when Christianity was officially adopted.

The Latin term is *consecratio*, the Greek *apotheosis*, probably a coinage of the Hellenistic epoch, and occasionally used in a weakened sense. The squib of the philosopher Seneca on the memory of Claudius (d. A.D. 54), *apocolocyntosis* ("pumpkinification"), is evidence that, as early as Seneca's lifetime, *apotheosis* was in use for the recognition of a departed emperor as a god.

It also indicates how much contempt might be associated with this pretended worship. The people, says the historian Suetonius, fully believed in the divinity of Julius Caesar, hinting at the same time that this was by no means the case with the majority of the apotheoses subsequently decreed by the senate. Yet Marcus Aurelius was still worshiped as a household divinity in the 4th century and was earlier believed to impart revelations in dreams. Antinous, the favourite of Hadrian, was adored in Egypt a century after his death. The ceremonies attendant on an imperial apotheosis are fully described by Herodianus. The most significant was the liberation of an eagle, which was supposed to bear the emperor's soul to heaven. Sharp-sighted persons had actually beheld the ascension of Augustus and of Drusilla, the sister of Caligula.

Representations of apotheoses occur on several works of art; the most important are the apotheosis of Homer on a relief in the Townley collection of the British museum, that of Titus on the arch of Titus, and that of Augustus on a magnificent cameo in the Louvre. *See* also ANCESTOR WORSHIP.

APPALACHIAN MOUNTAINS, the general name of a mountain system in eastern North America extending from Newfoundland, Gaspé peninsula and New Brunswick in Canada 1,200 mi. southwestward to central Alabama. The whole system may be divided into three regions: the northern from Newfoundland to the Hudson river; the central from the Hudson to the Kanawha river in West Virginia and Virginia; and the southern from the Kanawha river to central Alabama. The northern region includes the Shickshock mountains and Notre Dame range in Quebec, scattered elevations in Maine, the White mountains of New Hampshire and the Green mountains of Vermont. The central region comprises the Ridge and Valley province between the front of the Allegheny plateau and the Great Appalachian valley, the Allegheny plateaus of New York, western Pennsylvania and West Virginia and a large portion of the Blue Ridge.

The southern region consists of a large portion of the Piedmont plateau sloping to the east and bordering on the Atlantic coastal plain, the prolongation of the Blue Ridge, the Great Smoky, Black and Unaka ranges of North Carolina and Tennessee and the Ridge and Valley province adjoining the Cumberland plateau on the west, with some lesser ranges. A remarkable feature of the Appalachian belt is its longitudinal valley, the Great Appalachian valley, which in the southerly regions divides the mountain system into two subequal portions, but in the northern section lies west of the Appalachian ranges of New England and Canada and separates them from the Adirondack group.

The mountain system has no axis of dominating altitudes but in every portion the summits rise to uniform heights and, especially in the central portion, the various ridges and intermontane valleys

APPALACHIAN MOUNTAIN SYSTEM, SHOWING APPROXIMATE DIVISIONS OF ITS THREE REGIONS

have the same trend as the system itself. Mountains of the Long range in Newfoundland reach heights of over 2,500 ft. In the Shickshocks of Quebec the higher summits rise to about 4,000 ft. In Maine 12 peaks exceed 4,000 ft., including Katahdin (5,268 ft.); in the White mountains a number of summits rise above 5,000 ft., including Mt. Washington (6,288 ft.); in the Green mountains the highest point, Mansfield, is 4,393 ft. The Blue Ridge, rising in southern Pennsylvania and known there as South mountain, attains elevations of about 2,100 ft.; southward to the Potomac its altitudes diminish, but in Virginia a maximum is reached at Mt. Rogers (5,720 ft.). In the Ridge and Valley province of Pennsylvania the ridges rise generally to about 2,000 ft., and in Maryland Eagle Rock and Dans Rock are conspicuous points reaching 3,160 ft. and 2,895 ft., respectively. In the southern region of the Blue Ridge is Grandfather mountain (5,939 ft.), with three other summits above 5,000 ft. The Unaka, Black and Smoky mountains have 18 peaks higher than 5,000 ft. In the Black mountains, Mitchell (6,684 ft.), the culminating point of the whole system, is the highest peak in the U.S. east of the Mississippi. In the Smoky mountains, Clingmans Dome (6,642 ft.) is the highest peak.

In the central region the rivers—Delaware, Susquehanna, Potomac—heading in the Allegheny plateau run southeastward into the Atlantic. These rivers cutting across the grain of the Ridge and Valley topography form great gorges called water gaps. South of the Kanawha river the Appalachian ranges are drained westward by the Cumberland and Tennessee rivers, tributaries of the Ohio river. In the northern section the water parting lies on the inland side of the mountainous belt, the main lines of drainage (Hudson, Connecticut, Penobscot rivers) running from north to south into the Atlantic.

Geology.—The rocks of the Appalachian belt fall into two divisions: granites and other massive igneous rocks, and a great succession of Paleozoic sediments. The crystalline igneous rocks are confined to the portion of the belt east of the Great Appalachian valley. The Paleozoic rocks of this area, assuming their greatest areal extent in New England and Canada, are always highly metamorphosed and very generally intruded by granites. The Paleozoic sediments, ranging in age from Cambrian to Permian, occupy the Great Appalachian valley, the Ridge and Valley and the plateaus still farther west. They are rarely metamorphosed to the point of recrystallization, though in eastern Pennsylvania shales are altered to slates, and coals, originally bituminous, are changed to anthracite in northeastern Pennsylvania (*see* PENNSYLVANIA: *Mining*) and to graphite in Rhode Island. The most striking and uniformly characteristic geologic feature of the mountains is their internal structure, consisting of innumerable parallel, long and narrow folds, always closely oppressed in the eastern part (Piedmont plateau to Great Appalachian valley), less so along a central zone (Great Appalachian valley and Ridge and Valley) and increasingly open on the west (Allegheny and Cumberland plateaus).

Folding of the rocks resulted from the operation of great compressive forces. Extensive and deep-seated crumpling was necessarily accompanied by vertical uplift, but once at least since their birth the mountains have been worn down to a lowland, and the mountains of today are the combined product of subsequent uplift and dissection by erosion. The longitudinal valleys were determined by the outcrop of soft shales or limestones, and the parallel ridges upheld by hard sandstones or schists. Parallelism of mountain ridges and intervening valleys is thus attributable to the folding of the rocks. For discussion of geologic processes *see* FOLD; GEOLOGY: *Physical Geology*. For specific occurrences *see* CAMBRIAN SYSTEM; CARBONIFEROUS SYSTEM AND PERIOD; DEVONIAN SYSTEM; SILURIAN SYSTEM.

Forests.—The region is well covered with forests yielding quantities of valuable timber. The most important trees for lumber are spruce, white pine, hemlock, cedar, white birch, ash, maple and basswood. In the central and southern parts of the belt, ash and hickory constitute valuable hardwoods, and certain varieties of the former furnish quantities of tanbark. In the south both white and yellow pine abound.

Influence on History.—From the time of early settlement the Appalachians were a barrier to the westward expansion of the English colonies; the continuity of the system, the tortuous courses and the roughness of its transverse passes, a heavy forest and dense undergrowth all conspired to hold the settlers on the seaward-sloping plateaus and coastal plains. The confinement of the colonies between an ocean and a mountain wall led to the fullest possible occupation of the continent's coastal border under existing economic conditions, conducing to a community of purpose and a political and commercial solidarity, which would not otherwise have developed.

In contrast with this complete industrial occupation, the French territory beyond the mountains was held by a small and very scattered population; its extent and openness added materially to the difficulties of a disputed tenure. Bearing the brunt of the contests against the French as they did, the colonies were undergoing preparation for the subsequent struggle with the home government. In the American Revolution the American armies fought toward the sea with the mountains at their back protecting them against Indians leagued with the British.

See also AMERICAN FRONTIER: *The First Frontier;* MIDDLE WEST.

Appalachian Trail.—Beginning on Mt. Katahdin in Maine, the Appalachian trail for hikers and backpackers stretches southward for more than 2,000 mi. to Springer mountain in northern Georgia, passing through 14 states, eight national forests and two national parks. The trail is maintained by trail and hiking clubs and on public lands co-operatively with government land-managing agencies. Primitive shelters and trailside campsites are provided along the route. At each of these areas, from 7 to 8 mi. apart, the hiker is expected to do all necessary work himself, including replenishing the stock of cut firewood. The co-ordinating organization for the various groups sponsoring trail activities is the Appalachian Trail Conference, Inc., Washington, D.C.

APPEAL, in early common law, was a process of criminal procedure by which an aggrieved party, frequently the relative of a homicide victim, could compel the trial of the alleged felon by resort to one of the early irrational modes of determining guilt or innocence, generally trial by battle. This form of private vindication was available though the accused had been previously tried and found innocent, or found guilty and pardoned. The appeal, in this sense, flourished until the rise of the modern jury trial. It fell into desuetude by the time of the Tudors, but it was not formally abolished until 1819.

The first section of this article deals primarily with appeal in United States law, with only such references to English law as are desirable for historical background. For the English and commonwealth law, *see* the second section below.

In recent times appeal has come to mean the resort to a higher court to review the decision of a lower court or to a court to review the order of an administrative agency. It also has had and continues to have technical meanings which distinguish one form of such review from another, as, for example, in the supreme court of the United States where the term signifies a review as of right as distinguished from review at the discretion of the court, on a petition for certiorari.

The concept of review of one court by a higher court in the Anglo-American legal system was probably derived from the hierarchical system of ecclesiastical courts. Judicial review of this sort has been known almost from the time English judicial courts became separated from the generalized function of the *curia regis*. Thus, the judgments of the local and manorial courts were subject to review by the court of common pleas, which in turn was subject to review by the court of king's bench. Almost from the beginning, too, the right of review has been hedged by a myriad of technicalities which differ greatly from jurisdiction to jurisdiction.

The Judicial Hierarchy.—The concept of appeals requires

the existence of a judicial hierarchy. It is possible for a court to review its own judgments. Thus, the judge at the trial level may be asked to consider whether errors in the trial require correction; this is usually done by a motion of the losing party asking for a new trial or similar relief. Such procedure, however, is not considered an appellate process. Similarly it is possible for one or more judges of a court to have a judgment reviewed by several or all of the judges sitting on the same level of courts. So, too, the entire appellate court might be asked to review its own decisions. Both of these situations are usually termed "rehearings" rather than appeals, although the concept of appeals in criminal cases developed from the notion of a trial court sitting *en banc* to review questions of law raised at a trial before a single judge. Again, by resort to the use of one of the so-called extraordinary or prerogative writs or of habeas corpus it is possible to call for a review of a judgment in civil and criminal cases. Once more, however, this does not take the form of an appeal. The notion of an appeal relates to the overseeing of an action of a lower court by a higher one, and this is predicated on the existence of such a hierarchy.

A typical judicial hierarchy will include: (1) trial courts of limited or special jurisdiction, frequently denominated magistrates courts, justices of the peace, small-claims courts, municipal courts, etc.; (2) trial courts of general jurisdiction which usually carry the name of district court, circuit court or superior court, and occasionally, as in New York, of supreme court; (3) a court of appellate jurisdiction, which may be the ultimate appellate court in the system and, if so, is usually called the supreme court. There may be, however, between the trial court level and the court of ultimate appeal an intermediate appellate court, generally bearing the name of appellate court, appellate division or court of appeals. In most instances, each court in the hierarchy is subject to review only by the court immediately above it. Frequently, however, an intermediate step may be omitted because the importance or immediacy of the problem calls for direct review of the trial court by the highest appellate tribunal.

The Right to Appeal.—Although the right of one appeal is provided in almost every case by statute in all common-law jurisdictions and by the constitutions of some states, it is not uniformly afforded (see *Thompson* v. *Louisville*, 362 U.S. 199 [1960]), and it is not yet considered by the supreme court of the United States to be one of those essential aspects of "ordered liberty" commanded by the due process clauses of the U.S. constitution (see *McKane* v. *Durston*, 153 U.S. 684 [1894]). Indeed, in criminal cases no right of appeal existed in England, with a few exceptions, until 1907, and in the federal courts of the United States, again with a few exceptions, until 1891. The national constitution does require, however, that where appeals are provided, at least in criminal cases, a defendant may not be deprived of his right of appeal because he cannot pay the cost of preparing the necessary documents (*Griffin* v. *U.S.*, 351 U.S. 12 [1956]).

Who May Appeal.—As a practical as well as a legal matter, only the party aggrieved by the order or judgment of a court is entitled to seek review of that order or judgment in the appellate court. Neither an outsider nor the party who has prevailed in securing the order or judgment for which he asked is permitted to secure a review of that order or judgment by a higher court. Where, however, persons not originally parties to the action have been permitted to intervene or have been represented by others, as in class actions, or have subsequently been made parties voluntarily or otherwise, they generally have the same rights of appeal as the original parties. One exception to this rule might be noted. In the federal courts, when the losing party has filed an appeal from the district court in the appropriate U.S. court of appeals, the party who prevailed at the trial court level may seek review by the U.S. supreme court before judgment by the court of appeals. The extraordinary nature of this process is underlined by the very few occasions on which the supreme court has been willing to indulge this form of review. What might also be considered an exception exists in criminal cases. In almost all jurisdictions the prosecution cannot appeal from a judgment entered on a verdict of not guilty. This disqualification, however, is not commanded by the federal constitution (*Palko* v. *Connecticut*, 302 U.S. 319 [1937]), and the states of Vermont and Connecticut do authorize appeals by the state from judgments of acquittal.

Appealable Orders.—Orders and judgments of trial courts may be divided into two categories for purposes of appeal: final and interlocutory. The U.S. supreme court has defined a final judgment as "one which ends the litigation on the merits and leaves nothing for the court to do but execute the judgment" (*Catlin* v. *U.S.*, 324 U.S. 229, 233 [1945]). The problem is, of course, more complicated than that formula would appear to make it (see *Cohen* v. *Beneficial Industrial Loan Corp.*, 337 U.S. 541 [1949]), but the formula will suffice for present purposes. In the course of a trial, a court is required to enter decisions which settle only subsidiary questions or some but not all of the ultimate issues. These decisions are regarded as interlocutory orders. All jurisdictions sanction appeals from final judgments. No jurisdiction authorizes appeals from all interlocutory orders. But the jurisdictions are divided on the question of allowing appeals from important interlocutory orders. New York, for example, is among the jurisdictions which do permit appeals from a wide variety of interlocutory orders. The final-judgment rule jurisdictions, on the other hand, include states like Illinois and until recently the federal court system. Even in jurisdiction of the Illinois type, however, some interlocutory orders are appealable. Thus, appeals are generally allowed from interlocutory injunctions. The federal courts have recently been required to apply a rule somewhere in between. Judgments disposing of some but not all of the ultimate issues are appealable if the trial judge certifies the desirability of such review (*see* Federal Rules of Civil Procedure, rule 54(b), and *Sears, Roebuck Co.* v. *Mackey*, 351 U.S. 427 [1956]), and since 1958 there has been authority to review all interlocutory orders provided (1) that the trial court certifies that the order involves a substantial question of law the resolution of which may expedite the disposition of the case and (2) that leave to appeal is granted by the court of appeals (28 U.S. Code, sec. 1292). The argument in favour of the final-judgment rule is that it prevents delay incident to a series of interlocutory appeals. The argument in favour of the interlocutory-appeal rule is that it provides an opportunity for final resolution of the case before trial in many instances, and in any event provides clear guidance to the trial court for conducting the trial on the basis of rules established by the appellate court. There is merit in both systems, but the 1958 federal compromise of the final-judgment rule may provide a median way which will lead to the best solution.

Form of Presentation of Appeal.—Generally the presentation of the appeal will be by one of two methods or a combination thereof. Frequently where the appeal is taken from a court of minor jurisdiction to a court of general jurisdiction, provision is made for trying the case anew, as though it had originated in the higher court. Though most usual in the appeal from justices of the peace, the *de novo* trial is authorized elsewhere, as, for example, in the review of Interstate Commerce commission orders by a federal district court. The more usual approach calls for the presentation of the appeal on the basis of the record of the trial court proceedings. Generally, in the United States, argument will be presented both in writing, in the form of briefs, and orally in the presence of the court. Oral argument in the United States is usually of severely limited duration, approximately one-half hour for each side in most courts and one hour per side for most cases in the U.S. supreme court.

Scope of Review.—Except where the trier of the facts, *i.e.*, the jury, or the trial court judge in a case tried without a jury, has reached patently erroneous conclusions, the appellate court will not ordinarily reconsider their resolution of the dispute between the parties over the facts to which the law is to be applied. Somewhat more control is exercised by the appellate court where the evidence in the trial court was presented in the form of documents, for then the trial court would have had no advantage over the appellate court in determining the credibility of the evidence adduced. While many jurisdictions provide for review of the facts as well as of the law by appellate courts, and

although the appellate court is almost never wholly restricted to corrections of errors of law, for most purposes it is only errors of law which it is called upon to consider. No longer does the existence of an error in the trial court proceedings require an automatic reversal of the lower judgment. First, the appellate court will not ordinarily even consider the impact of an error to which the counsel did not raise an objection in the trial court. Second, the appellate court will certainly not consider as a basis of reversal any error which was in fact invited by the complaining party. Third, and most important, is the rule that an error which was not likely to have affected the result will not provide a basis for reversal. This so-called "harmless error" doctrine by now has been adopted everywhere. It is perhaps best stated succinctly in rule 61 of the Federal Rules of Civil Procedure, which provides: "No error in either the admission or the exclusion of evidence and no error or defect in any ruling or order or in anything done or omitted by the court or by any of the parties is ground for granting a new trial or for setting aside a verdict or for vacating, modifying, or otherwise disturbing a judgment or order, unless refusal to take such action appears to the court inconsistent with substantial justice. The court at every stage of the proceeding must disregard any error or defect in the proceeding which does not affect the substantial rights of the parties."

The Functions of the Appeal.—Basically the appeal serves two functions. Its first and perhaps primary function is to assure the litigants that justice under the law has been done in the resolution of the specific controversy. Its second function is one which is perhaps peculiar to the Anglo-American system of law: it is the promulgation of rules of decision which will be binding on all lower courts within a judicial system, thus assuring uniformity of treatment and some measure of certainty and guidance to those whose actions bring them within the ambit of the rule.

GREAT BRITAIN AND THE COMMONWEALTH

Civil and Criminal Appeals.—In the English system of law the right to appeal from one court to another is created, and created exclusively, by statute. Two systems of appeal exist, the one in civil, the other in criminal matters, both having in common that the house of lords is the final court of appeal for each. In civil matters, when a final judgment has been given, appeal lies, without leave, from all three divisions of the high court of justice and, in some cases (see *Appeals From County Courts*, below), from the county courts to the court of appeal; from thence it lies either by leave from the court of appeal or, if that be refused, from the house itself (in practice the appellate committee) to the house of lords. This statement requires qualification when the relevant statute is other than the Judicature act or the County Courts act, since certain statutes confine the jurisdiction of the court of appeal to questions of law, excluding questions of fact, while others limit the right of appeal to the court of appeal, excluding appeals to the house of lords. Appeals from magistrates' courts or from quarter sessions by way of case stated (see *Criminal Appeals*, below) lie to a court of the appropriate division of the high court (*e.g.*, in matrimonial cases, to the probate, divorce and admiralty division) and from thence to the court of appeal only by leave of the divisional court or of the court of appeal.

Criminal Appeals.—In criminal cases appeals lie to the court of criminal appeal on questions of law alone without leave, and on other grounds on application to the court of criminal appeal or on the certificate of the trial judge that the case is fit for appeal, in all trials by indictment—in effect, all cases tried by assize courts or by courts of quarter session in the exercise of their original jurisdiction. The courts-martial appeal court (virtually the court of criminal appeal under another name) hears appeals from courts-martial. From magistrates' courts (except when, as stated above, the appeal is by way of case stated) appeal lies to quarter sessions. Under the Administration of Justice act, 1960, appeal from the court of criminal appeal lies to the house of lords only by leave of the court or of the house and on a question of law of general public importance. (It was formerly only on the fiat of the attorney general.)

Some explanation is here needed of the appeal by way of case stated. A case stated is not necessarily an appeal at all, but rather an action the parties to which, or at least one of them, seek the opinion of the court (rules of the supreme court, order 34, rule 1). In an arbitration, the opinion of the court may be sought in this way and, in this instance, before the court has pronounced upon it. But s. 88 (1) of the Magistrates' Courts act, 1888, provides that: "Any person who was a party to any proceedings before a magistrates' court or is aggrieved by the conviction, order, determination or other proceeding of the court may question the proceeding on the ground that it is wrong in law or in excess of jurisdiction by applying to the justices composing the court to state a case for the opinion of the high court on the question of law or jurisdiction involved." The justices may, if they consider the application frivolous, refuse to state a case, but if they should do so the applicant may request the high court to make an order of mandamus requiring the justices to state a case. At any rate, where the magistrates' courts are concerned the procedure by way of case stated is part of the appellate jurisdiction of the high court. Appeals from determinations of the divisional court lie to the court of appeal only by leave of the divisional court or of the court of appeal.

Appeals From County Courts.—Under the County Courts act, 1959, a party to proceedings in a county court who is "dissatisfied with the determination or direction of the judge in point of law or upon the admission or rejection of any evidence" may appeal to the court of appeal (s. 108). The leave of the judge is required when, broadly speaking, the subject matter of the action does not exceed £20 in value. Section 109 confers a right of appeal on questions of fact subject to the conditions there set out, the most important of which is that, in actions founded on contract or tort or for money recoverable by statute, the subject matter must, generally, exceed £200.

Interlocutory Appeals.—In interlocutory matters there is a right of appeal in the queen's bench division from the masters, and in the probate, divorce and admiralty division from the registrars, to the judge in chambers; the masters and the registrars being subordinate judicial officers with jurisdiction in interlocutory matters and, to a limited extent, power to make final orders also. In the chancery division either party has the right to ask the master to adjourn the matter to the judge in chambers, but the effect is much the same. From the judge in chambers appeal lies from the judge to the court of appeal only by leave of the judge or of that court, and from the court of appeal to the house of lords only by leave of the court or of the house.

Appeals in Habeas Corpus and Contempt Proceedings.—The Administration of Justice act, 1960, referred to above, creates rights of appeal in certain classes of proceeding where none had existed before. In cases of contempt of court, appeals are to go from the court of appeal, the court of criminal appeal and the courts-martial appeal court to the house of lords; from courts to which appeals generally lie to the court of appeal, to that court; and from inferior courts to a divisional court of the high court. Appeals are also provided for in habeas corpus proceedings where the release of a person has been refused. This act also empowers the high court, in cases where a criminal charge has been tried before a magistrates' court or, on appeal, before a court of quarter sessions, to vary a sentence.

Scotland and the Commonwealth.—Appeal procedure operates broadly on the same principles in Scotland and Northern Ireland as in England, and the final court of appeal is for each country the house of lords. For all other countries in the British Commonwealth, where there is any right of appeal to a court outside the country or territory concerned—as there is from Australia and several other self-governing countries as well as from

the colonies—it lies to the judicial committee of the privy council. This committee also has jurisdiction to hear appeals (and, technically, to advise the sovereign) in appeals from ecclesiastical courts in England.

Principles and Procedure.—Appeals are by way of rehearing, but where issues of fact are concerned this generally involves a reading or summarization of the evidence heard in the court below, not oral testimony by witnesses themselves. The court of appeal and the court of criminal appeal both have the right to hear witnesses but this is rarely exercised, and then only in exceptional circumstances, when important new material which could not have been discovered before the trial has been brought to light since. Appeals from magistrates' courts to quarter sessions are, however, conducted quite differently, and the case is presented afresh on behalf of the prosecution, so that the appellant is able to call what evidence he will on his behalf.

On questions of law the appellate courts exercise their own judgment independently, though points not taken below can be admitted before them only if all the relevant facts have been established; but on questions of fact they work within narrower limits. Where the facts permit only one inference, the court may draw it even when the trial has been by jury. When trial has been by a judge alone, the burden of satisfying the court of appeal that the judge was wrong lies on the appellant, and the court should not disturb his judgment unless it is plainly unsound, since he had the advantage of seeing and hearing the witnesses (*Watt and Thomas* v. *Duncan*, 1947, A.C. 484). When an order is within the discretion of the judge, and the crucial question is a matter of discretion and not of law, the appellate court should not interfere unless the judge exercised his discretion on wrong principles.

See COURT; COURT OF APPEAL; CRIMINAL APPEAL, COURT OF; PRACTICE AND PROCEDURE; SUPREME COURT OF THE UNITED STATES, THE; *see* also the Index entries under "Appeal" in the Index volume.

BIBLIOGRAPHY.—*The Annual Practice* (annually); 1st Earl of Halsbury, *Laws of England, Practice and Procedure*, 2nd ed. (1937), *Action*, 3rd ed. (1952). (W. T. Ws.)

APPENDICITIS is the inflammation of the vermiform appendix, which is a vestigial wormlike structure attached to the caecum. The caecum is the pouchlike beginning of the large intestine; into the caecum empties the small intestine.

The appendix does not serve any useful purpose as a digestive organ in man. It is essentially a "blind alley" kind of organ with a channel that is two inches or more in length, closed at one end and communicating at the other with the caecum. Intestinal contents may work their way into the appendix and then be expelled by the muscular activity (peristalsis) of the walls of the appendix. Any factors that prevent the appendix from propelling its contents into the caecum may lead to appendicitis, as pointed out by O. H. Wangensteen. Intestinal material in the appendix may be prevented from escaping into the caecum by a failure of peristalsis or by a blocking of the opening into the caecum. The blocking can be caused by fecal concretions (fecaliths), undigested food particles such as seeds or by swelling of the lining of the appendix.

When the appendix is prevented from emptying itself a chain of events develops. Increasing pressure within the appendix leads to edema, swelling and distention of the appendix; the swelling is further increased by mucoid secretions from the lining of the appendix. As the distention increases the blood vessels of the appendix may become closed off, leading to gangrene. Meanwhile, the bacteria normally found in this part of the intestine (colon bacillus especially) proceed to propagate in this closed-off pocket. The combination of increasing tension from within and weakening of the wall by gangrene may lead to a rupture or perforation of the appendix. If this intestinal pus pocket spills into the peritoneal cavity, peritonitis, a very serious and often fatal condition, develops.

Fortunately peritonitis is usually prevented by the protective mechanisms of the body. The omentum, a sheet of fatty tissue, often wraps itself about the inflammed appendix. Exudate that has the clot-forming properties of fibrin normally develops in the areas of inflammation, behaving like paste or glue and sealing off the appendix from the surrounding peritoneal cavity with the help of the omentum. This prevents, in many instances, the direct spread of pus or intestinal contents into the peritoneal cavity. By this localizing process a ruptured appendix may lead to an abscess instead of a generalized peritonitis.

Occurrence and Symptoms.—Appendicitis is most common in the second and third decade of life but may occur in the very young or old. Males are afflicted in somewhat greater numbers than females.

The symptoms of appendicitis are varied. In the so-called typical case the pain may first be noticed all over the abdomen, or only in the upper abdomen, or about the navel. It is often described as a "gas pain." It is usually not as severe as the excruciating colic of gall bladder or kidney stones. After one to six hours or more the pain may become localized to the right lower abdomen. Nausea and vomiting may develop some time after the onset of the pain. Fever is usually present but is seldom high in the early phase of the disease. The leucocytes (white blood cells) are usually increased from a normal count of 5,000–10,000 in an adult to 12,000–20,000. Tenderness develops in the right lower abdomen, and the sudden release of pressure of the palpating hand may cause pain (rebound tenderness).

Diagnosis.—When there is some variation in the anatomical location of the appendix the pain and tenderness may be misleading. If the appendix is lateral to or behind the caecum the tenderness may be in the right flank. If the appendix lies deep in the pelvis one may detect tenderness only on rectal or pelvic examination and even then it may not be easily demonstrated. When the appendix lies on the left side due to transposition of viscera or failure of normal bowel rotation during embryonic life, the symptoms occur on the left. In the youngster and the elderly person the symptoms are more difficult to evaluate.

Appendicitis is one of many causes of abdominal pain. Various diseases produce symptoms that closely resemble appendicitis; these diseases include acute inflammation of the gall bladder, perforating ulcer of the stomach or duodenum, diverticulitis (inflammation of a small pouch) of the sigmoid colon, intestinal obstructions, inflammation of the uterine tubes (salpingitis), rupture of a tubal pregnancy, twisted ovarian cyst, bleeding from a ruptured *corpus luteum* of the ovary and perforating cancer of intestine. In addition, appendicitis-like symptoms may be produced by pneumonia, heart disease, *herpes zoster* (shingles) and kidney infection or stones.

Many abdominal pains are due to digestive disturbances related to food and have no serious significance. Diarrhea is generally a symptom that goes with digestive disturbances, but its presence does not necessarily exclude the possibility of an infected appendix.

Persons who experience abdominal pain that might indicate the early phase of appendicitis or some other perforating disease of the intestine should refrain from eating and should avoid taking cathartics (laxatives). It is very important to avoid cathartics because they increase the muscular activity of the intestine, making it more difficult for the fibrinous exudate to seal off the area of inflammation that may shortly perforate. The cathartic can definitely lead to the development of peritonitis.

If the abdominal pain continues for an hour or more it is wisest to seek medical advice, and appendicitis should be suspected in all patients who have abdominal pain, irrespective of age. Appendicitis is particularly serious in the elderly.

Removal of a Diseased Appendix.—Once a diagnosis of acute appendicitis has been made the appendix should be removed by surgery as soon as the patient's condition permits. In the early phase of the disease, *i.e.* up to 12–20 hours after the onset of symptoms, the mortality and disability rates arising from an appendectomy performed by a qualified surgeon in a well-equipped hospital are extremely low. On the other hand the mortality rate after an abscess has formed may be 3%–5%, and if spreading peritonitis has set in the death rate may be 10%–15% or even higher.

The decision about operation is a matter of surgical judgment in which the probabilities of appendicitis or some other condition

that would also require surgery are weighed against the probabilities of a disease or disorder that produces pain similar to that of appendicitis but does not require surgery. Even if the diagnosis of acute appendicitis cannot be made with reasonable certainty (and experienced surgeons often cannot be sure) it is safer to operate and possibly remove a normal appearing appendix than to wait and observe the symptoms (sometimes they develop overnight) and then find that the appendix has ruptured and peritonitis has set in.

Occasionally the patient is not seen by a physician until several days to a week after the onset of the attack, and an abscess may already be forming. In some cases of this kind the patient may be placed on a regime of nothing by mouth, intravenous fluids and antibiotics with a view toward obtaining better localization of the abscess for drainage purposes. There are times when it is preferable merely to drain the abscess and wait two to three months before operating to remove the appendix.

When appendicitis leads to rupture and produces a generalized peritonitis the patient may go into a state of shock with low blood pressure, weak and rapid pulse, cold and clammy hands and feet, and an ash grey or blue-tinged complexion. This requires the most intensive supportive therapy such as administration of plasma, intravenous saline, dextrose, high concentrations of antibiotics and blood transfusions. If the patient's condition improves, the ruptured appendix may be removed by surgery, but a patient in profound shock may not survive the operation.

Nonsurgical Treatment.—There is evidence that the use of antibacterial drugs instead of surgery for the treatment of appendicitis is hazardous because important symptoms may become masked. The antibacterial drugs are, of course, of tremendous value in postoperative management and in preparing some of the complicated problems for surgery.

Many patients will survive an attack of appendicitis without developing a serious complication, such as abscess or peritonitis. However, it is much safer to have the acute appendix removed early in an attack than to resort to any type of nonsurgical treatment except where medical facilities or personnel are not available or adequate for safe surgical treatment.

APPENZELL is the name of a town and canton in northeastern Switzerland. The town is the political capital of Inner Rhoden, which comprises half the canton, and lies on the left bank of the Sitter in a hollow formed by the union of mountain torrents from the Säntis. Pop. (1960) 5,082, mostly German-speaking Roman Catholics. The town is full of fantastically gabled and painted houses with much good ironwork. Buildings include a stately modern church with a Late Gothic choir, an ancient chapel of the abbots of St. Gall (12½ mi. N.) whose summer residence was in the village, and two Capuchin convents, one for men (founded in 1588) and one for women (founded in 1613). The two great annual events are the *Landsgemeinde*, or open-air parliament, and the Corpus Christi procession in full local dress. The brass decorations on braces and belts and the gay handkerchiefs worn by the men are of traditional design, while the women's embroidered dresses and high lace headgear is particularly beautiful. Pastoral occupations, embroidery and weaving employ the people.

Weissbad, a cure and holiday resort, is 2½ mi. S.E. of Appenzell.

Appenzell Canton is entirely surrounded by that of St. Gall; both were formed out of the dominions of the prince abbots of St. Gall, whence the name Appenzell (*abbatis cella*). It belongs to the limestone zone on the north side of the main Alpine lines. The culminating point is Säntis (8,209 ft.) in the south of the canton. It is watered mainly by two streams that descend from Säntis, the Sitter and its tributary the Urnäsch.

By the middle of the 11th century the abbots of St. Gall had established their power in the land later called Appenzell, but as early as 1377 this portion of the abbots' domains formed an alliance with the Swabian free imperial cities and adopted a constitution of its own. In 1411 Appenzell was placed under the "protection" of the Swiss confederation, of which it became a member in 1513. Religious differences after the Reformation broke up the land into two half-cantons, each called *Rhoden*, a term said to mean a "clearing." From 1798 to 1803 Appenzell, with the other domains of the abbot of St. Gall, was formed into the canton Säntis of the Helvetic republic, but in 1803, on the creation of the new canton of St. Gall, shrank back within its former boundaries.

The north and west half-canton (or Ausser Rhoden) has a total area of 94 sq.mi., with a population (1960) of 48,920, mainly German-speaking Protestants. Its political capital is Trogen though the largest town is Herisau. Ausser Rhoden is divided into three administrative districts comprising 20 communes and manufactures cotton goods, muslins and embroidery. It sends one member (elected by the *Landsgemeinde*) to the federal *Ständerat* and three to the federal *Nationalrat* (elected by a direct popular vote).

The south or more mountainous half-canton of Appenzell (Inner Rhoden) has a total area of 67 sq.mi., with a population (1960) of 12,943, practically all German-speaking Roman Catholics. It is largely pastoral with numerous summer pastures. Inner Rhoden is extremely conservative and has the reputation of always rejecting any federal referendum. For similar reasons it has preserved many old customs and costumes. It sends one member (named by the *Landsgemeinde*) to the federal *Ständerat*, and one to the federal *Nationalrat*, while it forms but a single administrative district, though divided into six communes.

The canton of Appenzell is perhaps best known by its institution of *Landsgemeinden*, or primitive democratic assemblies held in the open air. This institution is of immemorial antiquity, and the meetings in both portions are always held on the last Sunday in April. The *Landsgemeinde* is the supreme legislative authority. Various old-fashioned ceremonies are observed at the meetings, and each member appears with his girded sword. The existing constitution of Inner Rhoden dates mainly from 1872, and that of Ausser Rhoden from 1876. The meeting for Inner Rhoden is held at Appenzell, that for Ausser Rhoden alternately at Hundwil (near Herisau) and at Trogen.

APPERCEPTION, a psychological term, refers to the final stage of perception in which something is clearly apprehended and is prominent in awareness. The term also refers to the process by which the apprehended qualities of an object are related to or articulated with already existing knowledge in such a way as to lead to understanding. Apperception is thus a general term for those mental processes in which an experience, sensation or perception is brought into connection with already existent and systematized ideas and is thereby explained, classified or, in a word, understood. The pre-existing knowledge with which the apperceived content is articulated is called the apperceptive mass (J. F. Herbart).

Apperception is defined not in the terms of a modern behaviourism but rather in the language of a psychology of mental content. The latter needed a concept to distinguish between an inattentive, unreflective, even peripheral sort of awareness and an attentive, clearly focused awareness that included that appreciation of context which gives the object identity and meaning. Though the term itself is little used, the doctrine that understanding and learning depend upon discovering relationships between new facts presented and the pupil's already existing knowledge and experience appears prominently, in one way or another, in almost all educational theories. *See* also Perception; Psychological Tests and Measurements. (H. F. Ht.)

APPERT, NICOLAS (also known as François Appert)

(1752–1841), French chef, confectioner, distiller and inventor, known as "The Father of Canning," was born in Châlons-Sur-Marne, Oct. 23, 1752. Publication of his *Art de conserver les substances animales et végétales,* in 1810, set forth the principle of heat-and-hermetic-seal cooking, which, with improved techniques, is still used in commercial canning. Self-educated, he performed his experiments at a time when chemistry was in its infancy and bacteriology nonexistent. Scientists later confirmed his recommendations, Pasteur acknowledging that in proposing what came to be known as "pasteurization" he only made a new application of Appert's method.

With sailors dying of scurvy at sea, soldiers forced to forage on campaigns and malnutrition often fatal to the civilian population, the French *Directoire* in 1795 offered a prize for a method of preserving food for transport. Appert, experienced in cooking, confectioneries, distilleries, breweries and groceries, began a 14-year period of experiment in a workshop at Massy, using apparatus of his own construction. He applied his theory of cooking foods in containers from which air was sealed out, using glass jars and bottles stoppered with corks and reinforced with wire and sealing wax, to about 70 different items (soups, fruits, vegetables, juices, dairy products, marmalades, jellies, syrups). Tests by the French navy were favourable and on Jan. 30, 1810, after investigation and approval by the Consulting Bureau of Arts and Manufactures, the minister of the interior awarded him a prize of 12,000 fr. on condition that he "write an exact and detailed description of these processes."

In his lifetime he supervised four editions of this work and with the prize money established in 1812 the first commercial cannery in the world—the House of Appert, at Massy. The firm remained in business until 1933. Appert also created the bouillon tablet, devised a method for extracting gelatin from bones without the use of acid, perfected a workable autoclave and popularized use of the round container for canned foods. In 1822 the Society for Encouragement of National Industry titled him "Bienfaiteur de l'humanite" for having freed mankind from dependence on local and seasonal harvests. Appert died at Massy on June 3, 1841. *See* CANNING, COMMERCIAL. (N. H. B.)

APPIA, ADOLPHE (1862–1928), Swiss stage designer who, more than any other man except Gordon Craig, was responsible for guiding the visual theatre away from the stronghold of realism. Through his classic sketches and writings he became the prophet of the New Movement in the theatre in both Europe and America. He was born in Geneva, the son of Louis Appia. Although his early training was in music, at the age of 26 he felt impelled to reform the visual theatre and pursued his theatre studies in Dresden and Vienna. Three years later (1891) he propounded his revolutionary theories of theatrical production, illustrated with his settings for Wagner's music dramas. In 1899 his *Die Musik und die Inscenierung* was published in Munich. In this book he established a hierarchy of ideas for achieving his aims: (1) the proper display of the movement of the living actor; (2) a plastic stage that should provide the actor with spatial projection; and (3) the interpretive value of mobile light. He subordinated painting but stressed the significance of colour in light. The combination of these three elements constituted the re-establishment of the space stage. He expanded his theories in a second book, *L'Oeuvre d'art vivant* (1921), published in Geneva.

Appia's theories and philosophy of the visual theatre are recorded in his writings and sketches, and they exerted far more influence on the theatre of the 20th century than did the few productions he actually designed. He collaborated with Jacques Dalcroze in his school at Hellerau on numerous experimental theatre and dance productions. In 1923–24 he designed *Tristan und Isolde* for the Scala opera with Toscanini conducting. The following year he designed both *Das Rheingold* and *Die Walküre* for the Opera house at Basle.

A memorial portfolio of Appia's designs for the theatre was published in Geneva in 1929.

APPIAN OF ALEXANDRIA (2nd century A.D.), Greek historian of the conquests of Rome, flourished during the reigns of the Roman emperors Trajan, Hadrian and Antoninus Pius. He held public office in Alexandria where he witnessed the Jewish insurrection in A.D. 116. After gaining Roman citizenship he went to Rome where he practised as an advocate. Through his friend Marcus Cornelius Fronto he became a procurator, possibly in an honorary capacity, when already an old man.

Apart from a lost autobiography, he wrote in Greek a *Romaïca* or history of Rome in 24 books, arranged ethnographically according to the peoples (and their rulers) conquered by the Romans. There survive complete Books vi (Spain), vii (Hannibal), viii, part 1 (Carthage), ix, part 2 (Illyria), xi, part 1 (Syria), xii (Mithradates) and xiii–xvii (the civil wars from the Gracchi onward). Extracts from other books survive in Byzantine compilations and elsewhere.

Untouched by Atticism, Appian writes in a Greek which is no longer classical. Not himself an able historian he nevertheless preserves much information of value by his transmission of earlier sources, especially in Book i of the civil wars dealing with the period from Tiberius Gracchus (tribune 133 B.C.) to Sulla (d. 78 B.C.), for which it is a main source.

APPIANI, ANDREA (1754–1817), Italian painter, the best fresco painter of his day, was born at Milan on May 23, 1754. He was made pensioned artist to the kingdom of Italy by Napoleon but lost his allowance after the events of 1814 and fell into poverty. His best pieces, which are in the church of Sta. Maria presso San Celso and the royal palace at Milan, almost rival those of his great master, Correggio. He died on Nov. 8, 1817. He is known as "the elder," to distinguish him from his great-nephew Andrea Appiani (1817–65), a historical painter at Rome.

Other painters of the same name were Niccolo Appiani (*c.* 1510) and Francesco Appiani (1704–92).

APPIAN WAY (VIA APPIA), the ancient high road from Rome to Campania and south Italy, was built in 312 B.C. by the censor, Appius Claudius Caecus. It first ran only 132 mi. to ancient Capua (modern Santa Maria Capua Vetere), but was prolonged to Beneventum (Benevento), Venusia (Venosa), Tarentum (Taranto) and Brundisium (Brindisi), probably by 244 B.C. The original road was evidently graveled; in 298 B.C. the footpath was paved in stone (*saxo quadrato*) from the Porta Capena of Rome to the temple of Mars (1 mi.); three years later the full width, which probably averaged at least 20 ft., was paved with lava (*silex*) to Bovillae, a colony of Alba Longa (*q.v.*), and further additions were made in 191 B.C. Elsewhere, the quality of the paving presumably varied. To Tarracina (Terracina) its course was almost straight, with steep gradients in the Alban hills. At Forum Appii it entered the Pontine marshes, which were partly drained to carry it, and in the time of Horace it was the practice to travel by roadside canal from Forum Appii. That this portion (19 mi., hence called Decennovium) belonged to the original scheme is shown by a milestone of about 250 B.C. from Ad Medias (Mesa); an earlier route had skirted the foot of the Volscian mountains and afterward was used as the post road until the 18th century. Under Nerva and Trajan there were extensive repairs, and to avoid the steep climb over the mountain on which Terracina stands, the cliff face was cut away to a depth of 120 ft. Despite further repairs by Theodoric (A.D. 486), this whole stretch became impassable in later times. Beyond Fundi (Fondi) the road struck through mountains to Formiae (Formia) and thence to Minturnae (Minturno) and Sinuessa (near Mondragone), towns of the Aurunci which had been conquered in 314 B.C.

On entering Campania, the road bore inland to Capua. For the traffic seeking the important Campanian harbours, this involved an awkward detour inland, which was eliminated in A.D. 95 by the building of the Via Domitiana along the coast. From Capua through the defile of Caudium (near Montesarchio) to Beneven-

FOTOTECA UNIONE, ROME

SECTION OF THE APPIAN WAY FROM ROME BEYOND ALBANO LAZIALE. THE SO-CALLED TOMB OF THE HORATII AND CURIATII IS ON THE LEFT

tum, the Appian way largely underlies the modern highway, as remains of bridges show. Between Beneventum and Brundisium the ancient road passed through Aeclanum (near Mirabella), Venusia and Tarentum; it was partly restored by Hadrian, but little remains of it. Another shorter but less easy route had run by Aequum Tuticum (either at Ariano or S. Eleuterio), Aecae (Troia), Herdoniae (Ordona), Canusium (Canosa di Puglia), Barium (Bari) and Gnatia (or Egnatia); under Trajan this was converted into the main highway, the Via Traiana, whose course is followed with minor changes by the modern highway. In the journey from Rome to Brundisium described by Horace (*Satires* i, 5) the route followed the Appian way to Aeclanum; thence he turned left to Ausculum (near Ascoli Satriano) by a side road (later called the Via Aurelia Aeclanensis) and joined the line of the Via Traiana at Herdoniae. Another secondary road, the Via Herculia, was built by Diocletian from Aequum Tuticum into Lucania, and intersected the Appian way near Venusia. Finally, the section from Tarentum to Brundisium was restored by Constantine about A.D. 315.

The Appian way was the oldest and most famous of Roman roads; it was celebrated by Horace, and Statius who called it *longarum regina viarum*, "queen of long-distance roads." It was administered under the empire by a curator of praetorian rank. The first few miles outside Rome are flanked by a striking series of tombs and monuments (*see* L. Canina, *La Prima parte della Via Appia . . .*, 1853). There are milestones and other inscriptions about its repair.

For descriptions of the remaining bridges and structures *see* Sir R. Colt Hoare, *Classical Tour through Italy* (1819); T. Ashby and R. Gardner, *Papers of the British School at Rome*, viii, 104 *et seq.* (1916); G. Lugli, *Forma Italiae I* (1926).

(M. W. F.)

APPIN, a coastal district of Argyll, Scot., bounded west by Loch Linnhe, south by Loch Creran, east by Benderloch and Lorne districts, and north by Loch Leven and Glencoe (*qq.v.*). It measures 14 mi. N.E.–S.W. by 7 mi. in breadth. The coast is beautiful, and inland the country is rugged and mountainous. The streams Coe and Laroch flow into Loch Leven, Duror and Salachan into Loch Linnhe, and Iola and Creran into Loch Creran. The leading industry is slate and granite quarrying.

Duror, Ballachulish and Appin are the principal villages. The last two are ports of call for steamers, and the Scottish Region railway branch line from Connel Ferry to Ballachulish runs through the coastland. Appin was the country of a branch of the Stewarts.

APPLE. The apple is the domesticated form of *Malus pumila*, Mill (*Pyrus pumila*, Koch), with possible admixtures of other *Malus* species, members of the pomoideae division of the family Rosaceae. It is the most widely cultivated and best-known tree fruit of temperate climates; the world crop, including cider apples, exceeds 700,000,000 bu. in some years. This article treats the subject under the following headings: History; Varieties; Climatic and Site Requirements; Planting, Cultivation and Management; Diseases and Insect Pests; Harvesting, Storage, Use; Production.

The apple is one of the pome (fleshy) fruits in which not only the mature or ripened ovary but the surrounding tissue becomes fleshy and edible. The apple flower of most varieties requires cross-pollination (*i.e.*, by pollen from another variety; the honey bee is especially active in the transfer) to give fertilization and a desirable fruit set by 2% to 4% of the bloom. After the "June drop," at which time the small fruits fall off in large numbers, the remaining fruits increase in volume in fairly uniform fashion. The end product, though varying markedly in size, shape, colour and acidity depending on tree and environmental character, is nevertheless usually roundish, two to four inches in diameter and of some shade of red or yellow.

History.—*Malus pumila*, the species from which cultivated varieties are mainly derived, is native to southeastern Europe and southwestern Asia. Some suggest that it originated in the region immediately south of the Caucasus. These apples were undoubtedly used for food by the earliest inhabitants, and improved selections had been made and varieties were recognized in Europe more than 2,000 years ago. Cato (3rd century B.C.) recognized seven different varieties. Apples were carried by the Romans throughout much of Europe, including Britain, and may in fact have been in many parts even earlier. Hundreds of varieties were recognized in Europe prior to the settlement of the Americas.

The earliest settlers in the new world took with them both seed and propagating wood of the better European varieties. Orchards of considerable size were quickly developed; about 1649 Gov. John Endecott of Plymouth colony exchanged with William Trask 500 apple trees of three years' growth for 200 acres of land. Apples from New England were exported to the West Indies at least as early as 1741 and Albemarle Pippins were sent from Virginia to England as early as 1759. The apple accompanied early traders and settlers from Europe to the southern hemisphere and was carried from Europe or North America to India, China and Japan.

As the wave of settlement moved across North America it was accompanied, if not actually preceded, by the beneficient distribution of seedling apple varieties, perhaps by Indians and trappers, certainly by itinerants who became local legendary figures, the more prominent of which was Johnny Appleseed (Jonathan Chapman) who planted extensively in Ohio and Indiana. Improved varieties were soon added. Plantings were made in California at least by 1853 and in the Yakima valley of Washington state about 1875.

Later plantings were somewhat cyclical; periods of comparatively high prices were followed by increased plantings. The ubiquitous local, farm-home or semicommercial orchard of earlier years practically disappeared in favour of a few larger scale centralized commercial orchards, highly specialized, mechanized and increasingly scientific in management.

Varieties.—Apple varieties do not reproduce true to type from seed and consequently are all vegetatively propagated by budding or grafting. Most varieties originated from chance seedlings possessing superior qualities. During the past 2,000 years, tens of thousands of seedling apples have been propagated and named as varieties throughout the applegrowing countries of the world. More than 7,000 varieties were recorded in the United States alone. Only a few of these stood the test of time and became important in production. Extensive programs of breeding to develop varieties having superior qualities either in fruit, resistance to disease, hardiness of trees or dwarfism for small compact trees were initiated especially in the United States, England, Germany, Sweden and the U.S.S.R.

Initially, the continent made extensive varietal contributions to Great Britain, after which the more acceptable selections and new developments were basic to plantings in North America and the southern hemisphere. During the 20th century the better U.S. varieties have been tested widely, and some met with favour. After World War II several prominent U.S. dessert varieties and

their newer sports (bud variations) were increasingly planted, not only in Canada, but in Latin America, the far east, the U.S.S.R. and even in France. Varieties, thousands in number, fall into three broad but not mutually exclusive classes: (1) Cider varieties, developed mostly on the continent and in England, are of three types: sharps, with more than 0.45% malic acid; the bitter-sweets, with more than 0.2% tannin; and the sweets. Commonly, they are blended for processing. (2) Cooking or culinary varieties have been developed primarily in the United Kingdom and on the continent. Substantial size, at least moderate acidity and firm, dense flesh are characteristic; Bramley's Seedling and Grenadier are among the favourites. (3) Dessert varieties, on which developments primarily focused, differ widely but tend to emphasize colour (particularly brilliant crimson), size, aroma, smoothness and perhaps crispness and tang. Many are relatively high in sugar, only mildly acidic and very low in tannin. Worcester Peramain, Cox's Orange Pippin and Blenheim Orange are English favourites.

Commercial production in the United States, particularly in the Pacific northwest, concentrates rather heavily on the Delicious and some of its red sports. The Delicious accounts for about one-fifth of the U.S. crop, the McIntosh for one-tenth of the total, followed by the Winesap, Jonathan, Rome Beauty and Stayman Winesap. Winter varieties make up fully 80% of the total crop.

Climatic and Site Requirements.—The apple thrives in favourable localities and sites from approximately 30° to 60° latitude both north and south of the equator. It may be grown to a limited extent, but not very successfully, at high elevations closer to the equator than 30° north or south, but since it requires a considerable period of dormancy (generally a total of at least 1,200 hours per year under 45° F. or 7° C.) culture in areas lacking a distinct winter period is unsuccessful. Northward, culture is limited by low winter temperatures and shortness of the growing season.

Temperatures of −40° F. will seriously injure or kill trees of most varieties. A period of approximately 100 days free of killing frost is required for even the hardiest, early-maturing varieties to develop a crop. Sunshine, particularly in the latter part of the summer and early autumn, is important in developing pleasing fruit colour. Water to support tree growth and the sizing of the fruit is normally available in sufficient amounts in the more humid regions; otherwise, irrigation is practised.

Topography is generally of more importance than soil in the selection of sites for apple orchards. Soils must be well drained; fertility can be added if not high enough. Rolling hilltops or the sloping sides of hills are preferred because they provide "air drainage," allowing the colder, heavier air to drain away to the valley below, not only during the winter but more especially during frosty spring nights when blossoms or young fruit would be destroyed by much exposure to freezing.

Location to the south and east of mountain ranges (in the northern hemisphere) gives some protection from extreme cold waves of winter, and location on the leeward side of large bodies of water moderates winter conditions somewhat besides delaying spring development of the apple tree until there is less danger of frost damage.

Planting, Cultivation and Management.—Nursery seedlings of hardy stock are budded to desired varieties or used as piece root grafts when about 18 months of age, then used for orchard planting one or two years later. Spacing depends on varieties, topography, mechanization and intentions as to intercropping and tree removal, but varies from something like 25 by 25 ft. to as much as 45 ft. Rows are commonly planted to a single variety to simplify spraying and harvest; not more than two rows of a single variety are planted adjacent—interspersed rows of other varieties are carefully selected to provide for adequate cross-pollination of the bloom.

Management during the 6 to 8 years prior to appreciable production may consist of little more than protection from competing vegetation and pests. Cultivation and fertilization, even mulching, may be practised. Intercropping is permissible. It is during this early period that most careful attention to pruning is required, especially during the first five years, so that the main scaffold branches will be well distributed along and around the leader trunk and at wide angles thereto so that weak crotches will not develop later to split under heavy fruit loads.

With full bearing, increased attention is given to fertilization. An annual cover crop may be grown if permanent sod is not used. Pruning may be done primarily to allow better sun penetration for even ripening and colouring of the fruit and to lessen tree breakage. A rigorous spraying regime must be followed, not only to protect against insect pests, but possibly to delay spring development, to thin the young fruit set and to hold the autumn drop of ripening fruit to a minimum.

Diseases and Insect Pests.—In all parts of the world, extensive spraying is required to produce high-quality fruits free of blemishes caused by diseases and insect pests.

The most serious insect pest in most parts of the world is the codling moth (*Carpocapsa pomonella*), the common apple worm. Spraying with arsenate of lead once or twice in very cool districts or as many as eight to ten times in certain warm, dry districts may be necessary to protect the fruit. Other serious insect pests include San José scale (*Aspidiotus perniciosus*) and several other scale insects, rosy aphis (*Anuraphis roseus*), woolly aphis, species of mites or so-called red spiders and a number of less important insect species.

The most serious and widespread disease is apple scab, caused by a fungus (*Venturia inaequalis*) that attacks the leaves and fruit; it is mainly controlled by spraying with forms of sulfur. Various canker diseases, as well as cedar rust and bitter and brown rots, affect apples in many parts of the world.

Storage troubles include storage scald, soft scald, bitter pit, brown core and internal browning, as well as several sorts of breakdown, spots and mold rots.

Harvesting, Storage, Use.—The proper time of harvest is a matter of technical judgment, related not only to the development of the fruit but also to the time and manner in which it is to be used. Yields per tree will range from small amounts for a young, small tree to 30 bu. or more for the large, mature tree. Each apple is removed by hand, care being exercised not to damage the spur buds, which will provide the bloom for the next year's crop, and not to bruise the fruit. They are perhaps washed and graded and packed in boxes or baskets. Though picking of the fruit has remained a hand job, processing and marketing have been largely mechanized.

Varieties ripening during late summer are generally of poor storage quality and are usually consumed shortly after they mature. Varieties which ripen in late fall may be stored for periods ranging from six weeks to as long as nine months for the best keeping sorts handled by the best methods. For long holding, temperatures only slightly above the freezing point of the fruit (ap-

SUCCESSIVE STAGES IN THE DEVELOPMENT OF APPLE (MALUS PUMILA) FROM FLOWER TO FRUIT

(Top) Longitudinal sections; (bottom) corresponding cross sections

ples freeze at about 28.5° F. or −2° C.) are desirable for fruit from most sections. Fruit from some areas having a cool growing season, as in England, may break down if held near freezing and holds better at 36° to 40° F. Most American apples are stored near 32° F. For home storage, apples should be kept as cool as possible, but above the point of freezing. When held at higher temperatures, they ripen and soften rapidly, ultimately becoming mealy, and soon lose much of their characteristic flavour. Wrapping apples in paper impregnated with mineral oil, or placing such paper in the packages in contact with the fruit, prolongs the holding season for most varieties, as does the use of film box liners. Storage in inert gases is somewhat practised.

Of the United States crop more than four-fifths is normally used as fresh fruit. An apple is not a high-calorie food; the several sugars of a large one provide about 100 calories. Pectin, malic acid, several minerals and vitamin C (ascorbic acid) are also present in considerable amounts. A little less than one-tenth of the total crop is used for vinegar, juice, jelly and apple butter. Nearly one-tenth is canned as pie stock and applesauce. Consumption of commercial apples as food in the United States in the late 1950s was about 22 lb. per capita per year, as compared with 30 lb. as recently as 1940. In Europe a larger fraction of the crop goes for cider, wine and brandy.

Production.—Though the number of apple trees of fruit-bearing age does not change much from year to year, the annual world apple harvest fluctuates rather sharply because of weather, fruiting characteristics of the orchards and economic conditions affecting completeness of harvest. World production before and during World War II averaged nearly 500,000,000 bu. per year, of which about one-fourth was grown for cider. Postwar production was established at a higher level, ranging to more than 700,000,000 bu. France and the United States have each produced an average of 100,000,000 bu. per year.

Europe.—Though Europe produces one-half to three-fifths of the world apple crop, most producing areas do not utilize intensive commercial practices. Central Europe, including France, Germany, Switzerland, northern Italy and the northern Balkan countries, is a region of heavy production. Most of the trees are on land used for livestock pasture. Most of the orchards are unsprayed, and the fruit produced is seriously blemished by insects and diseases. Much of it is used for cider making, particularly in France. For the region as a whole, apples are largely consumed in the area where grown. A few districts, however, have more intensive production practices and pack and ship fruit out of the local area; the most important of these are in Switzerland, northern Italy and in the Danube basin of Yugoslavia, Rumania and Hungary. Extensive apple planting, with good-quality varieties, is also carried on in the Ukraine and north Caucasus regions of the U.S.S.R. In England, Kent is by far the most important apple-producing county. Great Britain before World War II produced less than half the apples it consumed, but young orchards, at levels below 600 ft., were considerably expanded during and after World War II. Belgium and the Netherlands produce some apples for export, although apples are also imported, particularly in late winter.

North America.—The United States produces about one-sixth to one-fifth of the world's apple crop. Individual farm orchards represent a small and declining part of the total. Commercial apple orchards, found in almost every state, are most important in the Pacific northwest, in the areas south and east of the Great Lakes and in the foothills of the Appalachians. Washington is the leading producing state, with an annual crop ranging from 20,000,000 to 35,000,000 bu. of 48 lb. each. A considerable part of the western crop is grown under irrigation and, because of its high colour and careful handling, is important in the eastern and export markets. New York is the second state, with about 20,000,000 bu.; Virginia, Michigan, Pennsylvania and California are among the larger producers. Principal Canadian production is in British Columbia in the west and in Ontario and Nova Scotia in the east.

Asia.—Japan and Korea developed considerable apple production in the 20th century, all being used in those countries. No data were available in the 1950s on production in China and India, though the apple crop in certain areas reaches appreciable proportions.

Southern Hemisphere.—Important apple production occurs in Australia, New Zealand, Argentina and Chile, countries which export considerable quantities to northern markets, particularly Great Britain. The crop is harvested mainly in March and reaches northern markets when local supplies are largely exhausted. The principal centre of production in Australia is in the southeastern provinces of Tasmania and Victoria. In Argentina, production centres in the Rio Negro valley and on delta lands adjacent to Buenos Aires. The main apple production of Chile is near Santiago.

APPLEBY, a municipal borough (1885) and the county town of Westmorland, Eng., lies 25 mi. N.E. by road of Kendal, the county's administrative centre. Pop. (1961) 1,755. Appleby is built on a steep hill beside the river Eden, the richly wooded valley being flanked on the northeast by Milburn forest and Dufton and other fells, which rise to more than 2,500 ft. It lies on the main Leeds-Carlisle railway line. A market town whose principal trade is agriculture, Appleby is a centre for dairy produce and there is an ancient annual horse fair in June.

The Roman road between Brough and Brougham passed through Appleby, but the earliest settlers of whom there is evidence were Scandinavians. Before the Norman conquest the area was held by the Scots, and afterward the town rose to importance as the head of the barony of Appleby. This formed part of the province of Carlisle granted by William II to Randulf le Meschin (or de Meschines), who erected Appleby castle. Rebuilt in the 17th century, the castle retains a fine Norman keep, while its double moat recalls its position near the border. The impoverishment caused by Scottish raids, particularly in 1388, led to Appleby's decline and as late as 1515 the greater part of the town lay in ruins. Writers of the 16th and 17th centuries speak of it as a poor and insignificant village. The borough, whose first royal charter was granted by Henry II in 1179, received no charter between 1332 and 1528. The castle was held for the royalists in the Civil War. Two half brothers of George Washington were educated at the grammar school (founded 1574) and there are two old churches, 17th-century almshouses and many Georgian buildings.

APPLETON, SIR EDWARD VICTOR (1892–1965) British physicist who was awarded the Nobel Prize for physics in 1947 for his discovery of the Appleton layer of the atmosphere, was born at Bradford, Yorkshire, on Sept. 6, 1892. Educated at Hanson School, Bradford, and St. John's College, Cambridge, he worked from 1920 at the Cavendish Laboratory in Cambridge until appointed Wheatstone Professor of Physics at King's College, University of London, 1924. There Appleton attained an international reputation with his researches on the propagation of electromagnetic waves and the characteristics of the ionosphere (*q.v.*). He showed that radio waves of sufficiently short wave length to penetrate the Heaviside layer, the ionized region from which long electromagnetic waves are reflected, were reflected by another, upper layer of the atmosphere now known as the Appleton layer. This work was very important for broadcasting and in the development of radar.

In 1936 Appleton returned to Cambridge as Jacksonian Professor of Natural Philosophy, and in 1939 became secretary of the government's Department of Scientific and Industrial Research (DSIR), where during World War II he worked on radar and the atomic bomb. In 1949 he became principal and vice-chancellor of Edinburgh University. Appleton had been made a fellow of the Royal Society in 1927 and was knighted in 1941. He died at Edinburgh on April 21, 1965. (N. Ce.)

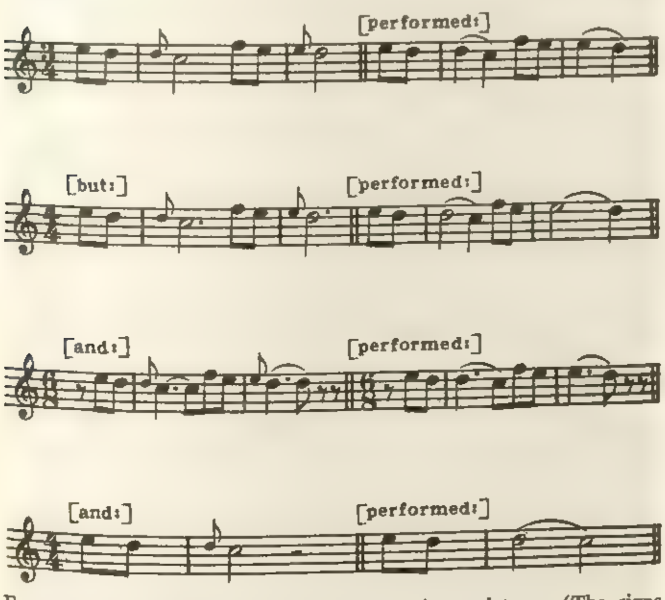
APPLETON, a city of Wisconsin, U.S., and the seat of Outagamie county, on bluffs above the lower Fox river, is about 100 mi. N.W. of Milwaukee. Lawrence college, founded by Amos A. Lawrence of Boston (chartered, 1847; first instruction, 1849), and the abundant water power brought about the first settlement in 1848. The city was incorporated in 1857. Power from the Fox river was first used in sawmills and later in flour and grist mills, which reached their peak about 1880. From the 1890s the chief manufactures included paper mill machinery and equipment, pulp and paper. The world's first commercial hydroelectric power plant went into operation at Appleton in 1882. The Institute of Paper Chemistry, a graduate school affiliated with Lawrence college, has an oustanding library on pulp and paper as well as the Dard Hunter paper museum. For comparative population figures, *see* table in WISCONSIN: *Population.* (W. F. RY.)

APPLIANCES, HOME: *see* HOME EQUIPMENT.

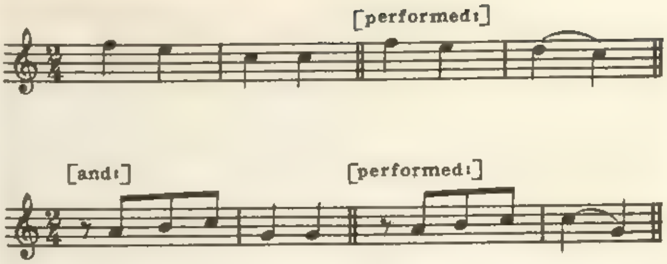
APPOGGIATURA, in music, an ornamental, and frequently unwritten, note of varying duration that temporarily displaces the main, written note, subsequently resolving on to it. The appoggiatura may stand at any interval to its main note but is most commonly adjacent; *i.e.*, at the distance of a tone or semitone, according to the prevailing tonality (unless contradicted by accidentals or the performer's preference).

The renaissance and early baroque appoggiatura was of moderate length, averaging one-third of its subsequent main note, and was more in the nature of a melodic than of a harmonic ornament. By the generation of J. S. Bach appoggiaturas became divided into two distinct species: the short (which takes an inconsiderable length from its subsequent main note and has, therefore, no substantial effect on the harmony) and the long (which takes upward of a half of the length from its subsequent main note and has, therefore, a very substantial effect on the harmony). All true appoggiaturas are taken on the beat (*not* before) and with some degree (often a high degree) either of accentuation or of expressive emphasis; the name, deriving from the Italian *appoggiare,* "to lean," describes this aspect unmistakably: it is necessary to lean on the ornament and subside on to the main note, above all with long appoggiaturas; and appoggiaturas are always slurred to their ensuing main notes.

The commonest baroque signs for the appoggiatura came to be little notes showing the pitch of the ornament, and apparently its duration; but this appearance is misleading and must normally be ignored. The duration is governed by the context, especially the harmonic context. The choice between a short and a long appoggiatura is not always obvious but can usually be made by responding to the natural implications of the music; in a few cases,



Example I: *Characteristic Long Baroque Appoggiaturas* (The signs here shown in the form of little notes are most commonly not present at all.)



Example II: *Characteristic Passages in Recitative Requiring Appoggiaturas (with no sign appearing)*

only one choice is compatible with the written harmony. Long appoggiaturas, however, are by far the most typical and should be given first preference in every suitable context. Certain rules existed for long appoggiaturas: standard lengths were half the duration of undotted notes; two-thirds of the duration of dotted notes; the whole duration of dotted notes in compound time if tied to a further note of the same pitch; and also the whole duration of notes followed by a rest if the main note can be forced forward into the time of that rest. These were described as minimum durations, which might be exceeded if the expression suggested so doing. There are, however, harmonic circumstances in which they must in fact be curtailed; and the decision is one that can ultimately be taken only by good musicianship.

Appoggiaturas are very frequently implied in baroque music without any sign or other written indication appearing in the notation. This is particularly the case in recitative, where to leave out an unwritten but implied appoggiatura is often tantamount to a wrong note.

In the 19th century, the same rules and treatment remained current, but there was an increasing tendency to incorporate the long appoggiatura into the ordinary notated figuration, instead of leaving it to the performer as an ornament shown only by signs or not at all. By the 20th century, this tendency had reached its logical conclusions: all long appoggiaturas, and almost all short ones, were fully and accurately written out as part of the normal text. As a result, the rules and treatment of ornamental appoggiaturas in earlier music had fallen into confusion, and many mistakes are made in performance through ignorance of the relevant conventions; but this ignorance is being increasingly corrected. (R. DO.)

APPOINTMENT, POWER OF, in Anglo-American law, a power given usually by a will or trust instrument by an owner of property to another person to dispose of an interest in the property either for his own benefit or for the benefit of one or more of a group specified by the creator of the power. *See* ESTATES, ADMINISTRATION OF; WILL; TRUST. (A. DM.)

APPOMATTOX, seat of Appomattox county, Va., 25 mi. E. of Lynchburg. The Confederate army of northern Virginia was surrounded there after an engagement with Federal cavalry on April 8, 1865. Three miles to the northeast is the site of the former county seat, known as Appomattox Court House, where Gen. Robert E. Lee surrendered to Gen. Ulysses S. Grant on Palm Sunday, April 9, 1865, thus effectively ending the Civil War. Appomattox Court House, virtually deserted after removal of the county seat to the new town of Appomattox in 1892, was made a national historical monument in 1940 and was restored to its 1865 condition. The Wilmer McLean house, where the surrender took place, was rebuilt and opened to the public. In 1954 the area was designated a historical park (about 968 ac.) (B. DA.)

APPONYI, ALBERT, COUNT (1846–1933), Hungarian statesman whose political philosophy blended the conservative traditions of his background with Hungarian nationalism and Bismarckian state socialism, was born in Vienna on May 29, 1846, of an ancient and famous family; his father, Count György Apponyi (1808–99), had been leader of the Progressive Conservatives and chancellor from 1846 to 1848. Albert Apponyi was educated at the Jesuit seminary at Kalksburg and at the universities of Vienna and Budapest. He then traveled widely. Entering the Hungarian parliament in 1872, he remained a member of it, with one short

interval, until 1918. From 1878 to 1905 he belonged to the "united opposition" in which all parties hostile to the Austro-Hungarian "compromise" (*Ausgleich*) of 1867 were represented. being, from the late '80s, its unquestioned leader. Even during this period he held important public positions and received marks of distinction from the crown. From 1906 to 1910 he was minister of education in the coalition government; the changes introduced by him in school curricula were greatly resented by the non-Magyars of Hungary for their Magyarizing tendencies. After the breakdown of the coalition he returned to the opposition as member of the Party of Independence, of which he became president on Ferenc Kossuth's death (1914). He was minister of education again in 1917–18. Returning to parliament after World War I, he headed the Hungarian peace delegation to Paris and several times represented Hungary at the League of Nations. He died in Geneva on Feb. 7, 1933, as Hungarian delegate to the disarmament conference. A cultivated man and a brilliant linguist and orator, Apponyi was always an imposing figure. It was, perhaps, the artificial atmosphere in which his public life was passed that prevented his being more. His published works include several versions of his memoirs (Eng. trans., 1935) and many studies on Hungarian constitutional problems.

See S. Pethö, *Le Comte Albert Apponyi* (1931). (C. A. M.)

APPORTIONMENT, in government, connotes the division of the burdens or benefits of citizenship (*e.g.*, the awarding to the voters of a certain district of the privilege of electing one legislator). (*See* APPORTIONMENT, LEGISLATIVE.) It also has a special significance in trust administration, indicating how the receipts from trust property, and the expenses of its administration, shall be allocated by the trustee—whether to the income account of the temporary beneficiaries or to the capital account of those who are ultimately to take the principal of the trust. *See* TRUST. (G. G. Bo.)

APPORTIONMENT, LEGISLATIVE. Legislative apportionment refers to the systems or principles according to which units of power are distributed in regular shares among the constituencies of a representative assembly; *i.e.*, on what basis citizens are represented in their legislatures.

The principle of equally shared influence was implicit in primitive assemblies wherein all tribal leaders, warriors, heads of household or nonslave citizens were directly represented by themselves or proxies. About 30,000 citizens were eligible to participate in the assembly of ancient Athens, although attendance never ran this high.

The king's courts and councils of later centuries held the seeds of national legislative institutions. The men who advised the king, helped finance his wars and petitioned him for favours usually fell into one of several classes or "estates": (1) the king's titled feudal tenants, or nobility; (2) heads of religious establishments, or clergy; (3) elected delegates from local corporate bodies (towns, boroughs, shires). The English Model parliament of 1295 consisted of two archbishops, 70 abbots and other clergy, seven earls, 41 barons, many knights of the shires and many burgesses of the boroughs. With the emergence of medieval parliaments in England and on the continent, these estates tended to consult separately, thereby establishing distinct "houses" as the basis for exercising influence in the king's councils; for example, two houses in England, three in France and four in Sweden. The prevalence of two-chamber arrangements in most modern legislatures is an outgrowth of the old estates, usually modified by a federal, nationality or geographical principle of apportionment in one house and a principle of direct popular representation in the other.

With the rise of nation-states, legislative functions of government became differentiated from executive and judicial. The articulation of the "national will" occurred increasingly through representative assemblies. After the British revolution of 1688, for example, English sovereignty rested with the king in parliament rather than with the king alone. Because they constituted influential shares in the nation's sovereignty, seats in parliament became more valuable, literally subject to auction and to contest between the landed aristocracy and the new merchant and industrial classes. As soon as governing power depended upon the successful organization of numbers of votes, the distribution of seats—hence of voting shares in national sovereignty—came under systematic examination among political philosophers and leaders. Principles of legislative apportionment were more methodically and mathematically stated.

More vigorously debated was the problem of how legislative seats could be distributed to reflect most accurately the national will. The growth of democracy, extension of the suffrage and rise of political parties added to the complexity of the problem of delineating constituencies. Practice varies widely, but experience permits the classification of constituencies into five types, as follows: (1) the territorial survey, which creates districts with special boundaries so that inhabitants or voters may be found in relatively equal numbers in each district; (2) the governmental entity, wherein geographically self-contained governing units (such as towns, counties, cities, states, etc.) are represented in legislative bodies at higher levels of government; (3) the official body that acts as a constituency—for example, the state legislatures that chose United States senators before popular election was established by the 17th amendment; (4) functional groupings of the population according to social or economic characteristics, such as the nobility, clergy and commoners of early parliaments, the classes of taxpayers in the Prussian system or the occupational, industrial, professional, nationality and other groupings used as the basis for apportionment in guild socialism and fascist corporate states; (5) groupings according to public opinion or party, usually found where systems of proportional representation are designed to reflect as many facets of voter opinion as possible. (*See* PROPORTIONAL REPRESENTATION; REPRESENTATION.)

Great Britain.—Legislative apportionments in major countries are based on different principles. Before 1832 the British house of commons (from "communes") was primarily a national assembly of representatives from local communities: the shires (later large rural counties) and the incorporated towns (later boroughs). The Reform act of 1832 altered the principle of community representation by imposing in addition a population criterion based on number of houses and a wealth criterion based on assessed taxes, thereby transferring about 143 seats from "rotten boroughs" to more heavily populated industrial towns. ("Rotten boroughs" were those completely under the control of the crown or a patron, some 50 of them having fewer than 50 voters and Old Sarum having only 7.) The Reform act of 1867 regularized the ratio of voters to population within the constituency classes of counties and boroughs. The Reform act of 1885 equalized representation between counties and boroughs on the basis of approximately 50,000 voters per constituency, with 576 of these as single-member constituencies, 18 others (including six university constituencies) returning two representatives each, and one (the Scottish universities) returning three members. The Redistribution act of 1948 permitted only one member from each constituency and made an allocation of seats among England (506 seats), Scotland (71), Wales (36) and Northern Ireland (12). The university seats were abolished, as well as the special parliamentary representation of the City of London (London financial district), in 1948, ending so-called "plural voting." Acts of 1944 and 1949 established constituency boundary commissions which would report every three to seven years regarding the need for boundary changes, the first British approach to periodic reapportionment. Peers and clergy continued to be represented separately in the house of lords.

United States.—Representation is apportioned in the senate according to the principle of equality among the states and in the house of representatives according to the principle of equally proportioned constituencies in the population. Each state in the union is entitled to two seats in the senate and to a number of seats in the house of representatives according to the ratio of its population to that of the nation. Every state is entitled to at least one house member, regardless of how small its population may be. The original constitutional apportionment set a ratio of one representative for each 30,000 inhabitants, counting all

Apportionment in U.S. House of Representatives

Under	Census		Apportionment effective		Whole number of representatives*
	Year	Population	Year	Ratio	
Constitution	..	..	1789	30,000	65
1st census	1790	3,929,214	1793	33,000	105
2nd census	1800	5,308,483	1803	33,000	141
3rd census	1810	7,239,881	1813	35,000	181
4th census	1820	9,633,822	1823	40,000	213
5th census	1830	12,866,020	1833	47,700	240
6th census	1840	17,069,453	1843	70,680	223
7th census	1850	23,191,876	1853	93,423	234
8th census	1860	31,443,321	1863	127,381	241
9th census	1870	38,558,371	1873	131,425	292

17th census	1950	150,697,361	1951	..	435
18th census	1960	179,323,175	1961	..	435

*There have been interim changes from time to time between apportionments, owing to admission of new states.

†Despite the constitutional requirements, congress failed to pass a reapportionment act following the 1920 census.

"free persons" but only three-fifths of "all other persons," notably slaves. By 1910 this ratio had become one representative for each 200,000 or more inhabitants. A 1929 act held the total number of house seats at 435, to be reapportioned on a semiautomatic basis according to one of several mathematical formulas subject to congressional choice. In 1941 the formula known as the method of equal proportions was established as the one to be used automatically. This method requires that a state receive an additional representative when its population, divided by the geometric mean of its present assignment of representatives and of its next higher assignment, is greater than the population of any other state divided by the geometric mean of the assignment of such other state and its next higher assignment. In order to compute the relative claims of each state, a priority list is prepared. In this way the difference between the representation of any two states is the smallest possible when measured both by the relative difference in the average population per district and also by the relative difference in the individual share in a representative.

The constitution provides for the apportionment of representatives among states, but is silent as to whether the representatives shall be elected by districts or by the state at large. By 1842, 22 states were electing representatives by districts and only 6 states were electing at large. At the same time the general ticket system was being widely accepted for presidential elections. The Apportionment act of 1842 provided that representatives under that apportionment be elected by districts composed of "contiguous territory equal in number to the representatives to which said state may be entitled, no one district electing more than one representative." Thereafter the practice of electing by districts became universal. Exceptions occurred according to the following principles: (1) If there is no change in the quota of a state, the existing districts continue until new ones are created. (2) If the quota is increased and there is no redistricting, the existing districts remain the same and the additional members are elected at large. (3) If the quota is reduced and there is no redistricting, all members are elected at large.

Each of the state legislative chambers has its own system of apportioning representation. Most states use county and town boundaries as much as possible in forming legislative districts. In some, constituencies are required to be as nearly equal in population as possible. In a few cases, weighted ratios are used to give additional seats to certain town or county units.

Problems.—Experience shows that certain practical political problems tend to recur in connection with legislative apportionment. As a system for sharing effective power, legislative apportionment has quite distinct meanings in dictatorships and democracies. Representative assemblies under dictatorships may simply be the continuation of an established system that has suffered political atrophy, or they may be an imitation of democratic forms created to give an illusion of democracy. Within democracies, on the other hand, legislative apportionment rarely accomplishes a division of power satisfactory to all interests. Often rural populations are overrepresented in proportion to urban populations. One political party may gain advantage over other parties under certain apportionment systems and practices, particularly where unnatural divisions are employed. Above all, most legislatures are reluctant to engage in reapportionments that might seriously affect the political futures of incumbent members.

Automatic periodic reapportionments or reapportionments initiated by specific responsible agencies or under clearly defined circumstances have occasionally been adopted by legislatures to overcome the inertia inherent in the reapportionment process. The U.S. supreme court's ruling (1962) in *Baker* v. *Carr* that federal courts had jurisdiction to hear suits alleging malapportionment in state legislatures further spurred efforts at effective reapportionment on the state level. In 1964 the court further ruled that congressional districts within each state must be substantially equal in population. *See* also REPRESENTATION.

APPRAISAL, REAL ESTATE, an estimate of the value of real property, or the process of making such an estimate. Real estate appraisals require the use of individual judgment; thus they are opinions rather than scientific determinations. Each appraisal is usually made in writing and always applies to particular property as of a specified date.

Not every estimate of the value of real property is an appraisal. Whenever real property changes hands, the buyer and seller have opinions about its value; whenever real property is taxed, the amount of the tax is usually based on a value estimate made by a public assessor. However, these opinions are not classified as appraisals for the term appraisal usually denotes a written opinion of value, the contents of which conform to generally accepted standards of quality.

Because value is a relation between an object and a person desiring it, several types of value can be imputed to any given property. The two most common types of appraisal involve the determination of fair market value and insurable value. Fair market value is the amount of money a given property can be sold for on the open market after being offered for a reasonable length of time, neither buyer nor seller being under duress and both being informed of all its feasible uses. Insurable value is the amount of money which would be compensable under an insurance policy in case of loss covered thereby. Less frequently used are appraisals of going-concern value, which is the worth of a property assuming continuation of its present use, and liquidation value, which is the amount of money a property would bring if it had to be sold immediately. Many other highly specialized concepts of value exist, but there is a growing tendency to confine use of the term appraisal only to estimates of fair market value and to use terms like "costing" or "valuation" for estimates involving other concepts of value.

Since ownership of real property essentially means possession of certain rights regarding it, every appraisal must specify which rights are to be evaluated. Real property consists of physically tangible and immobile objects, particularly the earth's surface, the land and minerals under the surface, the buildings and other objects permanently affixed to the surface and that portion of the airspace above the surface necessary for utilization of the surface itself. Ownership rights regarding such objects include the right to sell them, to occupy them, to use them, to give them away, to bequeath them, to enter them, to lease them to others and to refuse to do any of the foregoing. In many transactions, some of these rights are exchanged for other rights; *e.g.*, leasing a building consists of giving up the rights of use and occupancy in return for the right to receive rent. An appraisal may involve valuation of just one of these rights, a group of them or

all of them.

The process of making an appraisal can be analyzed into five major steps:

1. Identification of the problem. This consists of specifying the property involved, the rights to be appraised, the purpose of the appraisal, the type of value sought and the date at which the appraisal should apply.

2. Preliminary survey and appraisal plan. Next the appraiser determines what procedures and information will be necessary in making the appraisal.

3. Data procurement. The appraiser seeks both general data (concerning the region, city and neighbourhood in which the property is located) and specific data (concerning the particular site, the improvements thereon and the legal status of the property).

4. Analysis and valuation. These data are converted into valuation estimates in three different approaches to value. All three are derived from the principle that a reasonable man will not pay more for a given property than the present cost of purchasing another property which produces equivalent utility or money income.

a. One corollary of this principle is that the normal upper limit of value is "reproduction cost," *i.e.*, the cost of buying a similar site and building a structure on it identical to the one being appraised. In the cost approach the value of the property is estimated by calculating the cost of reproducing the buildings and other permanent improvements on it, plus the value of the land, minus allowances for depreciation caused by deterioration and obsolescence.

b. A second corollary is that a prudent investor will not buy a property which yields a lower rate of return than other available properties of equal risk. Therefore in the income approach a forecast is made of the net income the property would produce as an investment, and similar investments are examined to determine the rate of return commensurate with this degree of risk. Then a value is derived by dividing this rate into the predicted income, with proper allowances for recapturing the capital invested in buildings and other wasting assets.

c. The market date approach begins with an examination of current sales prices of similar properties. The value of the property being appraised is estimated at the price level of the similar properties, with plus and minus adjustments made by the appraiser for minor differences in size, age or other qualities. This method is preferred by most courts because it is easier to understand than the other methods.

5. Correlation of valuations. Any differences between the values arrived at previously are carefully analyzed and evaluated so as to determine which approach embodies the most relevant factors in the given case. In this manner, rather than by averaging his estimates, the appraiser arrives at a final value.

Most real-estate appraisers work for institutions engaged in real estate transactions such as mortgage houses, insurance companies, banks and governments. However, since 1930 an increasing number have become independent agents engaged solely in appraising. In the U.S. there are three national organizations of appraisers, each of which gives some of its members a special designation denoting professional qualification. The American Institute of Real Estate Appraisers, founded in 1932, awards the title "M.A.I." to each member. The Society of Residential Appraisers (1935) gives its senior members the designation "S.R.A." The American Society of Appraisers includes appraisers of commodities from fine arts to real estate and gives its senior members the title "A.S.A." In England the major professional organizations include the Royal Institution of Chartered Surveyors, the Chartered Auctioneers' and Estate Agents' Institute, the Chartered Land Agents' Society and the Incorporated Society of Auctioneers and Landed Property Agents. Similar societies exist in Australia, Canada and New Zealand. *See* also VALUATION.

APPRENTICESHIP, the learning of an art, trade or other calling by practical experience under the guidance of a master, perhaps also with some classroom study. The term is also commonly used to denote the period of time served by an apprentice. The length and nature of the apprenticeship are usually set forth in a contract entered into by the apprentice and his employer. Throughout history apprenticeship has been an important means of training skilled craftsmen; in the 20th century it remains a major method of training industrial workers and skilled craftsmen. There are brief references to apprenticeship in the Babylonian Code of Hammurabi (2100 B.C.) and in the history of Greece, Rome and China, but the English guilds of the middle ages provide the richest history of apprenticeship practice and are typical of developments in medieval Europe.

Guild Apprenticeship in England.—In the 12th century the craftsmen of English towns were associated in guilds in which masters were those skilled in an art, a science or a craft, and the apprentices were those who were learning its mysteries. Barristers were apprenticed to the law just as the sons of freemen might be apprenticed to a slater, a carpenter or an armourer. (*See* GUILD.)

Under guild rules, no master was allowed to take more apprentices than he could train properly and the method of training was rigidly prescribed, usually in a written contract or indenture. The period of apprenticeship was almost invariably seven years. During this period the master furnished food, lodging and clothing for his apprentice and attempted to train him in habits of industry and sobriety. When the full apprenticeship had been served the apprentice became a journeyman working for wages, or practised his craft as a master with his own journeymen and apprentices.

After obtaining certain privileges and exclusive rights the guilds began to abuse them. Difficulties were placed in the way of those who had served their apprenticeship and wished to become masters, and attempts were made to reserve craft privileges for those born into the guild. To avoid these restrictive measures, at the end of the 15th century journeymen began to set up as masters outside the towns, free of guild and municipal restrictions. The craft guild monopolies were further weakened by the growth of new trades and by the rise of the merchant companies. The decline of the guilds led to enactment of the Statute of Artificers in 1563.

The Statute of Artificers was primarily a consolidating enactment. It attempted to preserve a system which was beginning to break up and at the same time to bring uniformity to local variations. The act prescribed seven years as the period of apprenticeship and provided that no person might exercise a craft unless he had been apprenticed. At first this attempt to perpetuate guild apprenticeship seemed likely to succeed but the apprentice laws were not popular and were never uniformly enforced.

Guild (or domestic) apprenticeship rapidly declined during the 18th century. Three developments—the introduction of machinery in the great new manufacturing industries that were outside the scope of the apprentice laws, the growing dislike of all restrictions under a laissez-faire philosophy and the rise of capitalism—led to the repeal in 1814 of important parts of the statute of 1563. Thereafter a man might exercise any craft or trade he pleased, whether he had been an apprentice or not. The Act of 1814 marked the end of compulsory apprenticeship and (although it was not appreciated at the time) of domestic apprenticeship also.

Industrial Apprenticeship.—Long before 1814, in trades outside the scope of the apprenticeship laws, a new kind of apprenticeship had come into being. The apprentice no longer lived without wages and under the personal control of his master but lived with his parents and received wages. Despite the introduction of machinery and the increasing subdivision of labour, apprenticeship in its new form persisted as an important element in British industry.

At the end of the 19th century apprenticeship was threatened in another way. Employers became less willing to spend time and money on apprenticeship training, which the specialization of processes and the speeding up of production had rendered more difficult and more expensive. The trade unions, realizing that protection was needed against the employment of cheap juvenile

labour, called upon the time-honoured methods of the guilds and imposed restrictions on the number and proportion of apprentices and the conditions of their employment. British apprenticeship weathered difficult times during World Wars I and II, when military needs made consistent training programs impossible, and also during the interwar period, when depressed business conditions reduced the demand for skilled manpower.

Modern British Apprenticeship.—After World War II the ministries of education and of labour supported programs aimed at better education, recruitment and training of young people for industry. Apprenticeship was revitalized in large part through cooperative efforts of British industry and trade unions.

Five years became the standard term of apprenticeship; boys normally entered at 16 and were required to finish by the age of 21, because after that age union rules prohibited paying apprentices less than full adult wages. Most apprentices had attended secondary schools and had left at the age of 15 to work for a year before formally entering apprenticeship. In large firms, apprentices may begin with 12 months of common training, followed by specialized programs in different departments to learn all aspects of particular trades. Until the age of 18, apprentices are often allowed one day a week with pay to attend classes ("day release"), but this is not general; some apprentices attend evening classes and others are unable to secure any classroom training at all. There is no final examination required at the end of apprenticeship.

United States.—Apprenticeship existed in colonial times and served as a means of poor relief, education, penalty for idleness and punishment for debt. The indenture system of master-apprentice relations closely resembled English practice. With the development of the factory system during the 19th century, competitive pressures and laissez-faire government policy brought about a decline of apprenticeship standards. Without effective protection, apprentices were often poorly trained. Recognizing this threat, American labour unions toward the end of the 19th century increasingly enacted apprenticeship regulations themselves and sought enactment of apprenticeship laws by the government.

Acting independently, several major business firms in the 1870s and 1880s established apprenticeship programs, known as corporation schools, to provide a supply of trained craftsmen. Until after World War I, however, the need for skilled workmen in the United States was met primarily by immigration from abroad. Along with the restriction of immigration that came after the war, apprenticeship was encouraged by government policy.

Wisconsin legislation in 1911 and 1915 marked the beginning of effective governmental support. These laws made written apprenticeship agreements compulsory, required their registration, specified minimum standards of education, regulated wages and hours, specified training schedules and provided for supervision by the state industrial commission. At the federal level, the Smith-Hughes act of 1917 provided aid for vocational education and encouraged the establishment of trade schools in which industrial skills could be taught.

The Fitzgerald act of 1937 laid the groundwork for expansion of apprenticeship training in the United States under co-operative arrangements supported by federal and state governments, labour unions and employers groups, and continued the federal committee on apprenticeship first established under the National Industrial Recovery act (1933). This committee (including representatives of management, labour and government) was empowered to recommend policies and encourage program development. The U.S. bureau of apprenticeship within the department of labour maintained regional and local offices and approximately 30 state governments actively participated in promoting apprenticeship training but the primary responsibility for conducting such training remained with employers and unions at the local level.

Official standards for apprenticeship programs include the following: (1) Apprenticeable occupations normally require at least two years (4,000 or more hours) to learn, and apprenticeship terms average three and one-half to four years in length. (2) The starting age for apprentices is at least 16 but is usually higher, especially for returning veterans. (3) Definite schedules of work processes to be learned through training on the job should be followed. (4) Organized classroom instruction (usually a minimum of 144 hours per year) must be offered to provide the apprentice with technical knowledge related to the trade. (5) Progressive standards of wages, with periodic increases, must be set up. (6) Proper supervision of on-the-job training and adequate working facilities are required. (7) Periodic evaluation must be made of apprentice progress in job performance and related instruction, and records must be maintained. (8) Employer-employee co-operation, usually through union agreements, is essential. (9) Recognition must be given to apprentices for successful completion of training.

Thousands of local joint apprenticeship committees are in operation in the U.S., and apprentices are often indentured to these committees rather than to a single employer, being transferred from one firm to another as conditions may require. Apprentices are trained in more than 300 skilled occupations. At the completion of apprenticeship, an examination or the issuance of a license may be required.

After enactment of the Fitzgerald act mentioned above, and with the maintenance of full employment following World War II, apprenticeship training expanded substantially, especially with federal support being given to veterans entering apprenticeship following wartime service.

Apprenticeship rules have served several functions: they have protected apprentices by specifying minimum wage rates and other conditions of employment and training; they have assisted employers by providing a supply of properly trained craftsmen; and they have strengthened the unions by restricting the number of workers entering the trades. Unions have sometimes abused their restrictive powers but most unions have come to recognize that apprenticeship is not the only way to learn a trade and have therefore provided for admission by other means.

Apprenticeship in Europe.—Apprenticeship laws and customs in Europe vary from country to country. In Austria, for example, industrial apprenticeship and related vocational schooling are regulated by law. An apprentice usually learns his trade by working for three to four years with a master craftsman; apprenticeship training shops have been established by large firms, chambers of commerce, and trade union bodies. Practical training on the job is supplemented by part-time attendance at public vocational schools. On the completion of training, the apprentice must pass an examination; after several additional years, a "master's" examination permits him to become an independent craftsman.

In Belgium apprenticeship arrangements are quite flexible. They include training under contract with a craftsman (usually after leaving primary school) and the learning of skilled jobs within a factory. "Technical" instruction in the schools provides general and theoretical education, while "vocational" instruction emphasizes the practice of a craft. The Office National du Placement et du Chômage has encouraged the development of training centres operated by employers or by the O.N.P.C. itself.

In France the government has established *centres d'apprentissage* which offer three-year, full-time courses to teach skilled trades to apprentices, who usually enter at the age of 14 after completing primary education. Examinations are required and certificates awarded on completion. In addition, there are similar establishments run by industry, and some apprentices are under contract to individual enterprises.

In the Federal Republic of Germany apprenticeship requires three to three and one-half years of industrial training supplemented by part-time attendance at a vocational school. Detailed training syllabi are provided by the central authorities, with examinations at the completion of the program. Apprentices begin training at 14 or 15, after completing primary school. Certain industries (*e.g.*, chemical, electrical) have established training centres to meet their own special needs.

There are several means of entering skilled trades in Italy after leaving elementary school: (1) taking an apprenticeship in an enterprise; (2) taking a classroom apprenticeship course of one

to three years; and (3) attending vocational school for three years, followed by either (1) or (2).

In the Netherlands a boy planning to enter a skilled trade may take a two-year course at a junior technical school after completing his elementary education; if so, his apprenticeship in industry need be only two years. If he does not have the junior technical school certificate, his apprenticeship must last at least three years. All apprentices must attend classes on the theoretical aspects of their trades.

Around 1900 the Swiss cantons passed apprenticeship laws providing conditions for industrial training and supplementary schooling, with official supervision and support. The Federal Vocational Training act of 1930 established a unified, flexible program designed to produce good citizens, masters and foremen as well as craftsmen. The apprentice learns his trade through practical experience on the job, supplemented by a trade school program covering materials and methods, business procedures, economics and politics. (F. T. MA.)

Australia.—Apprenticeship is well developed in Australia, but a comprehensive public inquiry in 1954 made many recommendations for the improvement of its administration. Apprenticeship is regulated by commonwealth and state laws. Under legislation: (1) apprenticeship trades are defined, and unapprenticed youths are forbidden to enter them; (2) indentures (or their equivalent) are compulsory, and specified provisions and covenants must be incorporated in them; (3) the length of apprenticeship for each trade is stipulated within close limits; (4) a compulsory probationary or trial period at the commencement of the term is specified; (5) apprenticeship must be completed in early adulthood, rarely later than 23 years of age; (6) the contract must be registered with a government department, which has disciplinary powers against both parties without recourse to courts of law; (7) wages and conditions of employment (such as sick leave, annual leave, holidays, etc.) are prescribed by courts, commissioners, arbitrators and boards of *ex officio* decree, or after arbitration; (8) cancellation of the contract requires acquiescence of a government agency, and in some cases a government agency may dissolve the contract against the wishes of one or both parties to it; (9) limitation of the number, or proportionate number, of apprentices who may be taken by an employer is imposed by law (with, in most cases, power of dispensation vested in a government agency); (10) employers are subject to official scrutiny regarding their competence to train apprentices to required standards; (11) technical education for the apprentice, as distinct from practical training in the employer's plant, is an obligation on both apprentice and master.

New Zealand.—The Apprentices act (1948) makes provision for all matters affecting apprenticeship. The act is administered by a commissioner of apprenticeship who is assisted by district commissioners. All employers bound by awards or agreements filed under the Arbitration law are covered by the Apprenticeship act.

South Africa.—Under the Apprentices act (1944) a National Apprenticeship board was established. This board consists of representatives of employers, trade unions, education authorities and apprentices. The functions of the board are to co-ordinate the work of local apprenticeship committees and to make recommendations to the minister of labour on cognate matters.

Japan.—Joint apprenticeship schemes have been developed so as to enable small undertakings to share available training facilities.

Developing Territories.—Apprenticeship is inevitably less well established in the underdeveloped territories of Asia and the tropical zones. The training of juveniles in manual skills is, however, regarded as of considerable importance. Many of the larger American- and European-owned companies have excellent training schemes, but facilities for training apprentices are often entirely inadequate in the smaller enterprises. By the beginning of the 1960s government-sponsored training schemes were making a contribution, but there remained generally a widespread shortage of fully trained skilled workers calling for a more vigourous development of apprenticeship and other training schemes. *See* EMPLOYEE TRAINING; *see* also Index references under "Apprenticeship" in the Index volume. (B. C. R.)

APRAKSIN, FEDOR MATVEEVICH, COUNT (1661–1728), one of the architects of Peter the Great's navy, was born in 1661. In 1682 he was appointed table steward (*stolnik*) to the young tsar Peter, in whose warlike sports he subsequently took part and whose lifelong friendship he won. In 1700 he became governor of Azov and chief officer in charge of naval construction responsible for shipbuilding and such naval installations as the new harbour and fortifications at Taganrog. In 1707 he was promoted admiral and, in effect, supreme naval commander. In this capacity he took charge not only of the Baltic fleet but also of the army in the Baltic area. In the autumn of 1708 he repulsed the Swedes from Ingria, thus saving the navy and St. Petersburg, for which service he was rewarded with the title of count. In 1710 he conducted the victorious siege of Vyborg. In 1711 and 1712 he had to supervise the disbandment of the Azov fleet after Russia's defeat by the Turks on the Prut. From 1712 he commanded the army and from 1713 also the galley fleet, operating against the Swedes in Finland. In 1713 he occupied Åbo; in 1714 he took Helsingfors (Helsinki) and won Russia's first naval victory over the Swedes at Hangö (Hanko), an operation planned by Peter and ably executed by Apraksin. Its success and the occupation of the Åland Islands in 1715 put Sweden's southern Baltic shore at the mercy of Russian warships. It was Apraksin who led the landing on Gotland in 1717 and the devastating raid on the coast round Stockholm in 1719. The strategic advantage thus gained led to the conclusion, in 1721, of the peace of Nystad on terms favourable to Russia.

During the Persian campaign of 1722, Apraksin commanded the sea-borne expedition from Astrakhan to the Gulf of Agrakhan. In the reign of Peter I, he was three times tried for peculation but escaped with heavy fines. In 1726 he became a member of the secret supreme council and in the same year he led a task force sent to protect Reval (Tallin) against a possible British attack. He died in Moscow on Nov. 21 (new style; Nov. 10, old style), 1728.

APRICOT, the fruit of *Prunus armeniaca*. Like the plum and the peach, the apricot is a stone fruit, cultivated generally throughout temperate regions, and like those fruits it is used fresh for dessert or preserved by canning and drying. In tree, fruit and flower characters, the apricot is somewhat intermediate between the plum and the peach. Trees are large and spreading and in this respect are more like the peach trees. The leaves are broad, heart-shaped, dark green in colour and held erect on the twigs. The flowers are white in full bloom and borne singly or doubly at a node on very short stems. The apricot is self-fruitful and sets fruit when its blossoms are self-pollinated. The pit is smooth, somewhat like that of the plum but broader, somewhat flatter and more winged. The fruit is nearly smooth, round to oblong in some varieties, somewhat flattened and in general more like the peach in shape, but with little to no hairiness when ripe.

The flesh is typically an attractive yellow to yellowish-orange. The kernels of some varieties are sweet.

The apricot was once considered a native of the Caucasus and Armenia, hence the species named *armeniaca;* later studies, however, suggest that China is its native home. The fruit is cultivated in all of central and southeastern Asia and in parts of southern Europe and North Africa. It was, doubtless, among the fruits brought into southern California early in the 18th century by the mission fathers. The American Pomological society lists 11 varieties as grown in the United States in 1879. The apricot has been crossed with varieties of plum, particularly the oriental plum. Some of the more promising of these crosses have been introduced under the group name plumcot. No horticulturally satisfactory peach-apricot varieties, however, have been developed.

J. HORACE MCFARLAND CO.
APRICOT. ONE OF THE FRUITS HAS BEEN OPENED TO EXPOSE THE STONE

Apricots are propagated by budding on peach or apricot root stocks, and the peach, plum and apricot may be readily intergrafted. The apricot does well on peach stock, but the peach on apricot is not entirely satisfactory. The tree succeeds in a well-drained, loamy soil, preferably light rather than heavy. Production of this fruit in the United States is restricted to regions where climatic conditions are favourable. Most varieties will withstand winter cold as well as peaches, but the blossom buds, opening earlier than those of the peach, are frequently killed by late freezes. The trees are quite drought resistant and under favourable growing conditions are long-lived. Some trees have been found which are estimated to have lived 50 to 100 years or longer.

The commercial production of the apricot in the United States is confined largely to the Pacific coast and intermountain states. The annual production of the commercial crop is about 200,000 tons, with California accounting for a large proportion of the tonnage. In some years of large yields more than 70% of the crop has been dried. Other apricot-producing countries are Iran and Syria in Asia, and Spain, France, Italy and Yugoslavia in Europe. (F. P. C.)

APRIES, the Greek name for Haa-ib-ra Wah-ib-ra (also called Ouaphris in Greek and Hophra in Hebrew), fourth king of the 26th Egyptian dynasty, who reigned from 588 to 569 B.C. and died in 567. Apries failed to help his ally Zedekiah of Judah against Babylon, but after the fall of Jerusalem received many Jewish refugees into Egypt. Later he took Sidon but failed in an attack on Cyrene. The Egyptians then elected their general Amasis (*see* Ahmose) as king instead (569 B.C.). Apries was imprisoned but escaped and, after a second battle, met his death. *See* Egypt: *History.* (M. S. Dr.)

APRIL (Lat. *Aprilis*), the fourth month of the modern calendar, with 30 days. The Romans considered the month sacred to Venus, and its name has been thought to derive from that of her Greek equivalent, Aphrodite. A more plausible etymology connects the name with Lat. *aperire* "to open," in reference to the unfolding of buds and blossoms at this season; the modern Greek word for spring (*anoixis* "opening") provides a good analogy. As in ancient times April 21 is still celebrated as the *natalis urbis Romae,* the birthday of Rome. Many features of the Parilia, the Roman festival of herds and flocks, find a modern counterpart (and perhaps survival) in the observances practised on St. George's day, April 23, especially in eastern Europe. (F. R. Wn.)

APRIL FOOLS' DAY or All Fools' Day, named from the custom of playing practical jokes or sending friends on fools' errands, on April 1. Although it resembles the Hilaria of ancient Rome (March 25) and the Huli festival of India (ending March 31), the custom is probably of independent origin. Its timing seems related to the vernal equinox, when nature fools mankind with sudden changes from showers to sunshine. It is a season when all people, even the most dignified, are given an excuse to play the fool. In France the fooled person is called a fish (*poisson d'avril*). In April comes the cuckoo, emblem of simpletons; hence in Scotland the victim is called "cuckoo" or "gowk," as in the verse: "On the first day of Aprile, Hunt the gowk another mile." Hunting the gowk was a fruitless errand; so was hunting for hen's teeth, for a square circle or for stirrup oil, the last-named proving to be several strokes from a leather strap. (A. McQ.)

A PRIORI AND A POSTERIORI. These phrases mean literally "from the earlier" and "from the later" respectively. They were used originally to distinguish between arguments from causes and arguments from effects, but they have been employed by philosophers since Kant's time to distinguish between knowledge that is independent of all particular experiences and knowledge that is not.

The first recorded occurrence of the phrases is in the writings of the 14th-century logician Albert of Saxony. Here an argument a priori is said to be "from causes to the effect" and an argument a posteriori to be "from effects to causes" (C. Prantl, *Geschichte der Logik im Abendlande,* iv, p. 78, 1870). Similar definitions were given by many later philosophers down to and including Leibnitz, and the expressions still occur sometimes in nonphilosophical contexts with these meanings. Thus a man might be said to argue a priori if he inferred the guilt of an accused person from the fact that he had been convicted many times before. It should be remembered, however, that medieval logicians used the word "cause" in a wide sense corresponding to Aristotle's aitia and did not necessarily mean by prius something earlier in time. This point is brought out by the use of the phrase *demonstratio propter quid* ("demonstration on account of what") as an equivalent for *demonstratio a priori* and of *demonstratio quia* ("demonstration that, or because") as an equivalent for *demonstratio a posteriori.* Hence the reference is obviously to Aristotle's distinction, knowledge of the ground or explanation of something (*to dioti*) and knowledge of the mere fact (*to hoti*).

It was probably their connection with this antithesis between necessity and fact that made the phrases a priori and a posteriori seem suitable for use in the context in which Kant employed them in his *Critique of Pure Reason.* What we claim to know without recourse to experience is always some necessary truth such as a theorem of mathematics, whereas that which is known only from experience is not seen to be necessary. It is unfortunate, however, that the phrases have come to be applied generally to kinds of knowledge and even sometimes to kinds of concepts. For in this context they are by no means self-explanatory.

Although the use of a priori to distinguish knowledge like that which we have in mathematics is comparatively recent, the interest of philosophers in that kind of knowledge is almost as old as philosophy itself. No one finds it puzzling that he can acquire information by looking, feeling or listening, but philosophers who have taken seriously the possibility of learning by mere thinking have often considered that this requires some special explanation. Plato maintained in his *Meno* and in his *Phaedo* that the learning of geometrical truths was only the recollection of knowledge possessed in a previous existence when we could contemplate the eternal ideas, or forms, directly. Augustine and his medieval followers, sympathizing with Plato's intentions but unable to accept the details of his theory, declared that the ideas were in the mind of God, who from time to time gave intellectual illumination to men. Descartes, going farther in the same direction, held that all the ideas required for a priori knowledge were innate in each human mind. For Kant the puzzle was to explain the possibility of a priori judgments that were also synthetic (*i.e.,* not merely explicative of concepts), and the solution that he proposed was the doctrine that space, time and the categories (*e.g.,* causality), about which we were able to make such judgments, were forms imposed by the mind on the stuff of experience.

In each of these theories the possibility of a priori knowledge is explained by a suggestion that we have a privileged opportunity for studying the subject matter of such knowledge. The same conception recurs also in the very un-Platonic theory of a priori

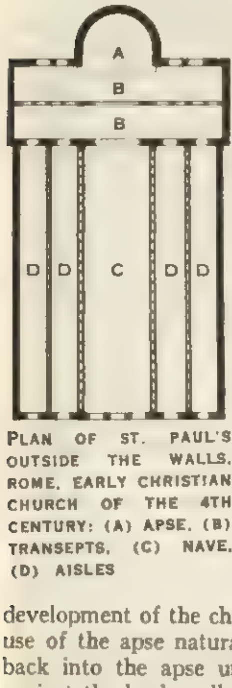
knowledge first enunciated by Thomas Hobbes in his *De Corpore* and adopted in the 20th century by those philosophers who call themselves logical empiricists. According to this theory statements of necessity can be made a priori because they are merely by-products of our own rules for the use of words. In favour of this conventionalist view it may be said that any truth that we know a priori must indeed be certifiable by reference to the rules which determine the meanings of the words or other signs in which it is expressed. But it is by no means obvious that such rules are all arbitrary.

See also Index references under "A Priori and a Posteriori" in the Index volume. (W. C. K.)

APSARAS, in Indian Vedic mythology, a water sprite. In the Rig-Veda the sea apsarases flow to Soma (*q.v.*). Though they are consorts of the Gandharvas (*q.v.*), they also wed mortals. They are also wives of Krishna Vasudeva.

APSE, in architecture, primarily a semicircular recess covered by a half dome. Hence, through the use of such a form to terminate the choir (*q.v.*) in early churches, the word is used, even when no vault is present, for any termination of a choir, a transept, an aisle or a chapel either circular or polygonal in plan. In Roman work, where the apse first appears, it occurred chiefly as an enlarged niche to hold and give importance to the statue of a deity in a temple. From this, the use of the form spread to other types of building, especially to the basilica (*q.v.*) as seen in the Imperial basilica in the palace of Domitian on the Palatine hill.

The apse form thus used was universally adopted by the early Christians as the climax of their churches. In the basilicas of the time of Constantine, in the western part of the empire the apse always faced the west. This was the orientation of the apse in old St. Peter's at Rome. During the 6th and 7th centuries, however, the usage in this matter gradually changed, so that churches in the west, like those in the east, had their apses toward the east and this has remained the custom ever since. The apse of the early Christian basilica was the place in which the clergy sat, the altar being situated between them and the rest of the church. This arrangement is still preserved in the apse of the cathedral at Torcello and in that of the church at Parenzo in Istria. In both cases there are semicircular benches of marble following the line of the apse and arranged in several stages, one above the other, like the seats of an ancient theatre. In the centre, on the axis, was the bishop's throne, raised above the clergy benches and approached by a flight of steps. With the development of the choir as the place for the clergy seats, the old use of the apse naturally disappeared and the altar was pushed back into the apse until, in many Renaissance churches, it is against the back wall.



PLAN OF ST. PAUL'S OUTSIDE THE WALLS, ROME, EARLY CHRISTIAN CHURCH OF THE 4TH CENTURY: (A) APSE, (B) TRANSEPTS, (C) NAVE, (D) AISLES

The apse was the place for the richest decoration in the church structure. It was sheathed with marble, frequently in elaborate patterns of light and dark, and the vault surface was covered with a glass mosaic in which some embodiment of the Godhead was the chief feature. At the end of the 6th century, liturgical changes rendered necessary the addition of other apses besides the main choir apse. These were frequently placed at the end of the side aisles but occasionally, when there was a transept, at the ends of the transept (as in the basilica at Bethlehem and in many examples of Coptic churches).

By the time Romanesque design was developing in western Europe, apse chapels had also been added to the church plan. This at once gave a great opportunity for enriching exterior design, until then severely simple, and led eventually to the development of that complex and magnificent combination of main apse and apse chapels known as the chevet (*q.v.*). In Italy, however, where chapels were usually confined to other portions of the church, the apse remained simple in form and gained its richness from the use of wall arcading, cornices and buttresses.

PHOTOGRAPH, "RADIO TIMES"—HULTON PICTURE LIBRARY

VIEW FROM THE CHOIR, LOOKING EAST, TOWARD THE APSE OF CANTERBURY CATHEDRAL

The apse, because of its shape, enclosed on one side and open on the other, gives great dignity to any object, such as an altar or statue, placed in its centre. It is, therefore, an admirable form with which to terminate any vista or to end any large hall, and it is so used in much modern secular work. *See* also BEMA; RELIGIOUS ARCHITECTURE. (T. F. H.)

APSE or APSIS, in astronomy and mathematics, either of the two points on an orbit that are nearest to or farthest from the centre of motion. They are called the lower (or nearer) and higher (or more distant) apses or apsides respectively. The line connecting these two points forms the "line of apsides," or major axis of the orbit.

APTERYGOTA, the name of the lower of the two subclasses of insects, not to be confused with Aptera, an antiquated term sometimes applied indefinitely to many wingless land arthropods. Apterygota are wingless, a condition apparently inherited from primitive ancestors before their flight organs had been developed. They are world-wide in their distribution and are noted for the generalized condition of many of their anatomical characters, especially for the possession of abdominal appendages. Many groups are seldom seen and only a few have been given common names. Collembola are generally called springtails or snow fleas, and Thysanura bristletails. The silverfish (*q.v.*) and firebrats, which inhabit houses, have become sufficiently well known, however, to receive accepted common names.

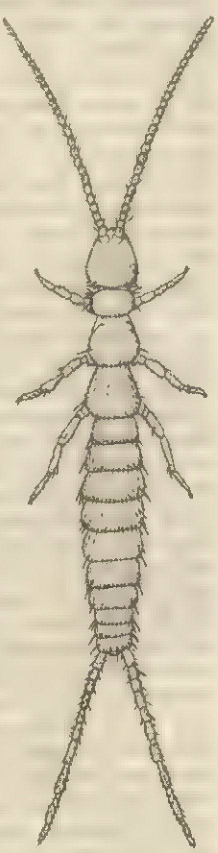
There is a tendency for some taxonomists to separate the Protura, Collembola and Diplura from the Thysanura, placing the first three in a separate class, the Entognatha, which is considered to be co-ordinate with the class Insecta.

The **Protura** (or **Myrientomata**) are very slender, minute, yellowish-brown hexapods, seldom exceeding 1.5 mm. in length. They are commonly found in the lower layers of moist ground litter of forests but occasionally are encountered, even in large numbers, in sphagnum or beneath loose bark. The abdomen of a proturan is composed of 12 segments in the adult. The 9th, 10th and 11th segments are obtained during postembryonic development, one of them being added at a time by a division of the terminal segment, or telson, into two segments.

The process of adding body segments following the embryonic stage is called anamorphosis. It is unknown among any of the other insects but is present in the millipeds and centipeds. Although clearly hexapod in their bodily organization, the peculiar method of development by means of anamorphosis in the proturans together with their possession of certain noninsectan anatomical characters have caused some students to recognize them as a class distinct from the insects, known as the Myrientomata. Fossil proturans have not been discovered.

The **Collembola,** or springtails, have the widest-known world distribution of any group of insects, being found on nearly all land masses regardless of size and in several places on the south polar continent. They occur in great abundance in the soil, in decaying vegetable matter of various kinds, in leaf mould and under loose bark. Some species are aquatic and are found on the surface of the water, a few occur on the snow, where at certain times of the year they congregate in great numbers, while other species live in close association with ants. Springtails vary in size from less than 1 mm. in length to more than 5 mm. They may be almost naked but usually are clothed with setae or scales, the latter giving them a metallic lustre. Although springtails that are provided with the jumping apparatus leap for considerable distances, the more common method of locomotion for most species is a crawling gait. Most springtails are without tracheae, but in the genus *Sminthurus* and some closely related genera tracheae are present. They open through a single pair of spiracles just behind the head. Most springtails are herbivorous, feeding on decaying vegetable matter, fungi, lichens, pollen, diatoms, algae and other lower forms of plant life. A few feed on higher living plants and may cause injury to greenhouse and truck crops. Some are known to be predaceous. Eggs of springtails usually are nearly spherical and are laid singly or in groups in the situation inhabited by the adults. The young are structurally almost the same as an adult but are smaller and frequently of a paler coloration. Individuals moult throughout life. Fossil springtails have been taken in Baltic amber, there being several genera represented. A fossil specimen found in Canadian amber possessed a pair of slender, divergent stylets instead of a true spring. For it the family Protentomobryidae has been created.

The **Diplura** (fig. 1) usually live in the soil, where many of them feed on decaying vegetation or on soft, living plant tissues such as root tips and root hairs. Because of their feeding habits, some species cause damage to growing plants. Some are known to be predaceous. The Diplura are long, slender, white or yellowish insects, and all species are blind. Those in the family Campodeidae possess two long, slender, segmented, apical abdominal appendages, while those in the family Japygidae bear, in place of these slender stylets, two forceplike apical structures resembling somewhat those of earwigs.



AFTER E. O. ESSIG
FIG. 1.—DIPLURAN (CAMPODEA FOLSOMI)

The **Thysanura** (fig. 2) are found in houses, beneath bark and boards, with ants or termites, or in the soil. Because of their long, slender, terminal appendages they are often called bristletails. Thysanura breathe through tracheae that open through paired spiracles. Their food habits have not been investigated exhaustively, but those species that invade houses will attack starchy materials, often causing extensive damage to books and papers. Thysanura are very active insects, running, dodging and jumping with great agility. The house pests prefer warm temperatures and do not exist out-of-doors in northern climates. Thysanura moult throughout their lives. The house-infesting forms grow slowly, maturing in from 3 to 24 months.

BY COURTESY OF ILLINOIS NATURAL HISTORY SURVEY
FIG. 2.—THYSANURAN, THE FIREBRAT (THERMOBIA DOMESTICA), A HOUSE PEST

CLASSIFICATION

Apterygotans may be separated into the following groups:

Order 1. Protura.—Antennae absent; mouth parts apparently withdrawn into the head; abdomen with 12 segments; first to third abdominal segments with appendages.

Order 2. Collembola.—Antennae present; mouth parts apparently withdrawn into head; abdomen with six segments, first always and third and fourth segments usually with appendages, the latter forming a jumping structure.

Suborder 1. Arthropleona.—Body elongate, segments of the thorax and abdomen usually distinct.

Suborder 2. Symphypleona.—Body short, swollen, globular; segments of the thorax and first to third of the abdomen ankylosed.

Order 3. Diplura.—Antennae present, composed of many segments; mouth parts apparently withdrawn into head; blind; abdomen consisting of 11 segments, ending in two long, slender, segmented cerci, or a pair of pincerlike structures.

Order 4. Thysanura.—Many-segmented antennae present; mouth parts not apparently withdrawn into head; eyes usually present; abdomen with 11 segments, ending in three long, slender, segmented stylets.

Suborder 1. Microcoryphia.—Body almost cylindrical in cross section, thorax arched; eyes present and well developed; ventral abdominal appendages well developed and sometimes used as a spring.

Suborder 2. Zygentoma.—Body flattened, nearly crescentric in cross section, thorax not strongly arched; eyes small, and absent in some groups; ventral abdominal appendages weakly developed.

See INSECT: *Classification by the Forms of Metamorphosis.*

BIBLIOGRAPHY.—Literature on the Apterygota is widely scattered and much of it was published many years ago. J. Lubbock's "Monograph of the Collembola and Thysanura," *Ray Society* (1876) is of both scientific importance and historic interest. American Collembola have been dealt with in numerous papers by J. W. Folsom, by H. B. Mills in his *Monograph of the Collembola of Iowa* (1934) and by E. A. Maynard in his *Monograph of the Collembola or Springtail of New York State* (1951). (H. E. E.; H. B. M.)

APTERYX, the genus name for the kiwis (*q.v.*), small flightless birds of remote regions of New Zealand. *See* also BIRD: *Types of Living Birds.*

APTITUDE TESTS attempt to determine and measure those characteristics of a person that are regarded as indices of his capability to acquire, through future training, some specific set of responses (intellectual, muscular, etc.). The tests assume that people differ in their special abilities, and that these differences are related in a predictable manner to their later achievements.

See PSYCHOLOGICAL TESTS AND MEASUREMENTS; DIFFERENTIAL PSYCHOLOGY; PERSONALITY.

APUANIA: *see* MASSA-CARRARA.

APULEIUS, LUCIUS (fl. 2nd century A.D.), Platonic phi-

losopher and rhetorician, author of *The Golden Ass,* the earliest Latin novel extant in its entirety, which secured for him an especial influence on modern fiction after the Renaissance, was born at Madauros in Numidia (near the modern Mdaourouch in Algeria), about A.D. 125. He was educated at Carthage and Athens and then traveled in the east, becoming deeply interested in initiation into religious mysteries. After practising as a rhetorician in Rome, he returned to Africa and married a rich widow, Aemilia Pudentilla. Her family disapproved of the union and accused Apuleius of having won her affections by magic arts. His defense (*Apologia* or *De Magia*) before the proconsul Claudius Maximus is the chief authority for his biography. The remainder of his life was devoted to literature and philosophy.

The work on which Apuleius' fame chiefly rests is the *Metamorphoses* or *The Golden Ass* (the latter title seems not to be the author's, but to have been bestowed in compliment), the narrative of the adventures of a young man changed by magic into an ass. The same theme was treated in a short extant Greek work called *Lucius, or the Ass,* attributed to Lucian, and in the lost *Metamorphoses* of Lucius of Patrae, of which Photius gives a brief report. The relationship between these narratives has been much discussed; probably that of Lucius of Patrae was the earliest and was used both by Apuleius for his elaborate version and by the author of *Lucius, or the Ass,* who gives the story a satirical turn. Apuleius' hero is in some sense also a portrait of the author, and one or two obviously autobiographical details are introduced. In the last book he is restored to human shape by the aid of Isis and finally becomes her priest.

The Golden Ass illustrates the contemporary reaction against a period of skepticism and also the influx of oriental and Egyptian ideas into the old theology. It also has a well-marked literary aim, defined by H. Kretschmann as the emulation of the Greek Sophists and the transplantation of their tours de force into the Latin language. The dignified, the ludicrous, the voluptuous, the horrible, succeed each other with rapidity; fancy and feeling are everywhere apparent, but not less so affectation and meretricious ornament. The style of the Latin is peculiar and has a strong archaistic colouring. The novel as a whole, however, is invaluable as an illustration of ancient manners and is full of entertainment. The "Cupid and Psyche" episode (bk. iv–vi) has been much imitated: in English there are poetical treatments of it by Shakerley Marmion (1637), by Mrs. Tighe (1805), by William Morris (in *The Earthly Paradise*) and by Robert Bridges (1885, 1894); and Walter Pater introduces it in *Marius the Epicurean.* Likewise, Don Quixote's adventure with the wineskins and Gil Blas's captivity among the robbers are borrowed from Apuleius, and several of the humorous episodes reappear in Boccaccio.

Of Apuleius' other writings, the *Florida* is a collection of excerpts from his declamations, ingenious but highly affected. The little tract *De Deo Socratis* expounds the Platonic doctrine of beneficent daemons, an intermediate class between gods and men. Two books on Plato (*De Platone et eius Dogmate*) treat of his life and his physical and ethical philosophy; the third, a spurious work on logic called *Peri hermeneias* or *De philosophia rationali,* was much studied in the Middle Ages. The *De Mundo* is an adaptation of the treatise *On the World* wrongly attributed to Aristotle. Apuleius asserts that he also composed many poems and several works on natural history.

Among works falsely attributed to Apuleius should be mentioned *Asclepius,* a Latin version of an important Greek Hermetic dialogue.

BIBLIOGRAPHY.—Of the collected works of Apuleius the first edition is by Joannes Andreas (1469); later editions are by F. Oudendorp, 3 vol. (1786–1823), by G. F. Hildebrand, 2 pt. (1842) and by R. Helm and P. Thomas (1907–31). *See* further the *Index Apuleianus,* ed. by W. A. Oldfather, H. V. Canter and B. E. Perry (1935); H. Kretschmann, *De Latinitate L. Apulei* (1865); H. Koziol, *Der Stil des Apuleius* (1872).

For the *Metamorphoses* separately *see* the editions by F. Eyssenhardt (1866) and by D. S. Robertson and P. Vallette, 3 vol. (1940–45); also P. Médan, *La Latinité d'Apulée dans les Métamorphoses,* new ed. (1926). For the relation between the *Metamorphoses* and *Lucius, or the Ass* see Erwin Rohde, *Über Lucians Schrift* Λούκιος (1869); K. Bürger, *De Lucio Patrensi* (1887); B. E. Perry, *The Metamorphoses Ascribed to Lucius of Patrae* (1920). There are English translations of *The Golden Ass* by W. Adlington (1566; rev. by S. Gaselee for the Loeb Classical library, 1919); by T. Taylor, with the philosophical works also (1822); and by Robert Graves (1951). Of the "Cupid and Psyche" episode there are separate editions by O. Jahn and A. Michaelis (1883; 5th ed., 1905) and by L. C. Purser (1913).

For the *Apologia,* see the editions by I. Casaubon (1594) and by H. E. Butler and A. S. Owen (1914); also A. Abt, *Die Apologie des Apuleius von Madaura und die antike Zauberei* (1908). For Platonic works and the treatise *On the World* see the edition by A. Goldbacher, *Apuleii Madaurensis opuscula quae sunt de philosophia* (1876). For the *Asclepius* see the *Corpus Hermeticum,* ed. by A. D. Nock and A. J. Festugière, vol. ii (1945).

APULIA, a part of southeast Italy once inhabited by the Apuli, a Samnite tribe (*see* SAMNITES) around Mt. Garganus (Promontorio del Gargano) on the east coast. They mingled with the Iapygians who had come from Illyria, so the district reached the border of ancient Calabria. A rare monument of the Samnite language is the famous *Tabula Bantina* from Bantia on the Lucanian border, a late and important record of the Oscan (*q.v.*) dialect with some southern peculiarities. Dating between 118 and 90 B.C., it shows that Latin had not then spread over the district (*see* LUCANIA). Far older are coins from Asculum Apulum (modern Ascoli Satriano) and Teate (later known as Teanum Apulum, now scanty ruins), the earliest being of the 4th century B.C. Of the few Roman or Latin colonies Luceria (Lucera) and Brundisium (Brindisi) were the chief. The Romans developed the migration of flocks; sheep tracks (*tratturi*) 350 ft. wide, leading from the Abruzzi into the plain of Apulia, date at least from Roman times. Large-scale sheep farming was detrimental to the towns and risings occurred until the Social War. Apulia, with Calabria, formed the second region of Augustus. Hannibalic and later wars, according to Strabo, destroyed the prosperity of the country; in imperial times little or nothing was heard of it. Both Apulia and Calabria were governed by a *corrector* from Constantine onward, but in 668 the Lombards conquered Calabria and Apulia and the former name was transferred to the territory of the Bruttii, the name Apulia being extended to include Calabria also. In the 9th century the greater part of this territory was recovered by the Byzantine emperors.

Teate was the first capital, then Luceria, a military post, and then, under the empire, Canusium (Canosa di Puglia). The old road system consisted of the Via Appia (*see* APPIAN WAY), the Via Traiana and the coast road, more or less parallel east-southeast. The first, east from Beneventum (Benevento), entered Apulia at Pons Aufidi (Ofanto bridge) and ran to Venusia (Venosa), Tarentum (Taranto) and Brundisium. The second, northeast from Beneventum, turned east at Aecae (Troia) and ran through Herdoniae (Ordona), Canusium, Butuntum (Bitonto), Barium (Bari) and Egnatia (Gnatia) to Brundisium. A short cut, from Butuntum to Gnatia through Caelia (Ceglie del Campo), ran inland. The third parallel line ran north of the Via Traiana, entering Apulia near Larinum (Larino), and thence, keeping to the plain south of Mt. Garganus, rejoined the coast near Manfredonia at Sipontum (with a branch at Aecae through Luceria and Arpi just north of Foggia to the Via Traiana). It then passed through Barduli (Barletta) where it was joined by a road from Canusium by way of Cannae to Barium, where it joined the Via Traiana. From Barium a road probably ran through Caelia south-southeast to the Via Appia, some 25 mi. N.W. of Tarentum. Barium was an important harbour, though less so than Brundisium and Tarentum, which, however, belonged to Calabria. (For the modern region and later history *see* PUGLIA.)

APURE, a state of southwestern Venezuela, is one of the most typical llanos states; area 29,537 sq.mi., pop. (1961) 117,577. Cattle raising dominates life, and the size of a ranch is often measured by square leagues (old Spanish unit equivalent to 4,439 ac.). Some ranches exceed 1,000,000 ac. and as many as 4,000 calves are branded at a single roundup. San Fernando de Apure, the capital, has the largest packing house in the country, from which fresh beef is flown daily to Caracas and other large cities. Several dry-season highways run deeply into the state from the north and west. (L. WE.)

APURE RIVER, one of the major tributaries of the Orinoco, has its source in the Cordillera de Mérida of Colombia several

hundred miles to the west and flows northeast and east through the heart of the llanos into the Orinoco. The best part of the llanos lies between the Apure and the northern mountains. The river's principal affluents, including the Portuguesa and the Guárico, flow mostly from the north. During the rainy season (May to November), it is navigable for small steamers from Ciudad Bolívar to the important towns of Nutrias and San Fernando de Apure. The Apure's tributary area is a famous cattle country. Including its headstreams, the river is 509 mi. long. (L. WE.)

APURÍMAC, a department in the interior of southern Peru; area 7,975 sq.mi., pop. (1961) 303,648. Most of the department is at a high elevation, but with deep canyons cut into the highland surface by the Río Apurímac and its tributaries. The inhabitants are mainly farmers and sheep herders. The chief products are wool (from sheep and alpacas), meat, maize, barley, wheat and potatoes. At lower elevations sugar cane, fruit and cotton are grown. The mines are worked for gold, copper, lead and salt. The capital, Abancay, located about 83 mi. W. of Cuzco, is in the centre of the largest area of settlement, located in an intermontane basin that lies between 7,000 and 8,000 ft. above sea level, where sugar cane can be raised. The department was formed in 1873. (P. E. J.)

APURÍMAC RIVER, in south central Peru, one of the headwaters of the Amazon. It rises in the Laguna de Villafro at the north base of the Cordillera de Chilca, 7 mi. from the village of Cailloma. For some 429 mi. it flows northwest and north-northwest through the heart of the Andes, descending from over 15,000 to less than 860 ft., where it joins the Urubamba to form the Río Ucayali. For most of this length it flows through narrow canyons, and its course is frequently interrupted by falls and rapids. It is known as the Apurímac only as far as Puerto Bolognesi at the junction of the Río Mantaro. From this point as far as Puerto Prado at the junction of the Perené it is called the Ené, and thence to the junction with the Urubamba it is called the Río Tambo. Because of its torrential nature and the narrowness of its valley bottom, few people live along the river. It forms much of the Cuzco department western boundary. Its main affluents are the Pampas and Pachachaca. (P. E. J.)

AQABA (AL 'AQABAH), the only sea outlet of the Hashemite Kingdom of Jordan, lies at the head of the Gulf of Aqaba, the northeastern branch of the Red Sea. Pop. (1961) 8,908. It was probably the site of the biblical Elath, and under the Romans it was a military post called Aelana. The old town is built largely of mud brick, with gardens and palm groves down to the water's edge; a ruined castle of the 14th century A.D. stands near the old jetty. There is a small airport, but communication with the interior is mostly by road. It was little used as a port in World War I, developed in World War II, and by the 1960s handled over 400 vessels and more than 700,000 tons annually. (G. W. L. H.)

AQABA, GULF OF, the Sinus Aelaniticus of antiquity, the eastern of the two northern arms of the Red Sea. Varying in width from 12 to 17 mi., it is 100 mi. long, penetrating into northwest Saudi Arabia and the Sinai peninsula (Arabia Petraea) toward the north-northeast. The gulf is in a pronounced cleft with hills rising abruptly from the shore, often to 2,000 ft. The entrance is narrowed and made difficult by Tiran and other islands, while navigation is precarious because of numerous coral reefs and sudden squalls. The gulf is part of the complex Jordan–East African rift valley system, being a southward continuation of the Jordan-Araba depression. At its head the gulf is 5 mi. wide, and there the Egyptian-Israeli, Israeli-Jordanian and Jordanian-Saudi Arabian boundaries converge, giving Israel and Jordan each about 9 mi. of coast line.

The only sheltered harbour in the gulf is at Dahab 33 mi. from the entrance, but both Israel and Jordan, urgently needing outlets to the sea, have created ports at Eilat (Elath) and Aqaba. Aqaba is at the eastern side of the head of the gulf and has a good water supply and refreshing palm groves. Since medieval times it has been a recognized stronghold on the pilgrim route from Egypt to Mecca. It is the site of the biblical Elath (Eloth). The Romans called it Aelana, a military post with paved road up the valley of Wadi Itm to Ma'an and Petra. In the 10th century an Arab geographer described it (Haila or Ailat) as a great port of Palestine and the emporium of the Hejaz. It suffered at the hands of Saladin (12th century), and fell into decay until 1841 when its regular use by Egyptian pilgrims was acknowledged by Turkey's recognition that the Sinai peninsula and Aqaba belonged to Egypt. In 1892 Turkey resumed possession of Aqaba. In 1917 Col. T. E. Lawrence (*q.v.*) and the Hejaz army captured it. Aqaba was then administered together with Ma'an, Petra and Shaubak as part of the Hejaz kingdom until 1925, when Great Britain, fearing a Wahhabi attack, ejected King Husain (*see* HUSAIN IBN ALI) and occupied the Aqaba-Ma'an province. This area later became part of the Hashemite Kingdom of Jordan. During the 1950s the development of the port of Aqaba and improvement of its road and air links with the interior of Jordan were put in hand under agreement between Great Britain and Jordan. The tiny port of Eilat, founded in 1949 (pop. [1961] 5,326), has grown as a result of interference by Egypt with Israeli shipping passing through the Suez Canal and the development of the Negev. An oil pipeline was laid from the port to the Haifa refinery, and an asphalt road built to Beersheba. The port is also served by a small airport. (A. B. M.)

On May 17, 1967, in the course of a Middle East crisis, President Nasser, on behalf of the U.A.R., demanded the withdrawal of the UN force stationed since 1956 at Sharm el Sheikh on the Tiran Strait at the mouth of the gulf. When the UN secretary general complied with his request, Egyptian troops occupied Sharm el Sheikh. Nasser thereupon closed the gulf to all Israeli shipping and to all shipping carrying strategic goods to Israel. Sharm el Sheikh was recaptured by Israeli forces on June 7. (X.)

AQUAE (Lat. "waters"), a name given by the Romans to sites where mineral springs issued from the earth. More than 100 can be identified, some declaring by their modern names their ancient use: Aix-les-Bains in Savoy (*Aquae Sabaudicae*), Aix-en-Provence (*Aquae Sextiae*), Aix-la-Chapelle or Aachen (*Aquae Grani*), etc. Two occur in Britain: *Aquae Sulis*—less correctly *Aquae Solis*—at Bath (*q.v.*) and Buxton (called *Aquae*).

AQUAMARINE, a transparent variety of the beryllium ore beryl (*q.v.*). It is valued as a gem, having a delicate blue or bluish-green colour, suggesting sea water. Emerald is the green variety of beryllium. Aquamarine occurs usually where ordinary beryl does, the finest coming from the U.S.S.R. *See* also GEM.

AQUA REGIA is a mixture of concentrated nitric and hydrochloric acids, usually one part of the former to three parts of the latter by volume. This mixture was given its name by the alchemists because of its ability to dissolve gold and other "noble" metals. Aqua regia and similar mixtures are used in chemistry to dissolve substances that resist being placed in solution.

The solvent action on gold, for example, is caused by the oxidation of the metal by nitric acid and by the ability of the chloride ion (from the hydrochloric acid) to bind the oxidation product, the auric ion (Au^{+++}), in a stable complex, tetrachloraurate ion ($AuCl_4^-$). The formation of this complex ion reduces the concentration of the oxidation product and drives the reaction in the desired direction. The complete chemical reaction can be represented by the equation: $Au + NO_3^- + 4H^+ + 4Cl^- = AuCl_4^- + NO + 2H_2O$. The effect of the chloride ion on the ease of oxidation of gold is reflected in the large lowering of the oxidation-reduction potential of the metal: $E = -1.50$ v. ($Au = Au^{+++} + 3e$) in the absence of chloride, and $E = -1.00$ v. ($Au + 4Cl^- = AuCl_4^- + 3e$) in the presence of chloride.

When the aqua regia solution of gold is concentrated by evaporation, nitrosyl tetrachloraurate ($NOAuCl_4$) is obtained; if an excess of hydrochloric acid is present, tetrachlorauric acid, $HAuCl_4 \cdot 4H_2O$, crystallizes out.

Aqua regia dissolves platinum and palladium rapidly, but the other platinum metals, iridium, osmium, rhodium and ruthenium, are less readily attacked; the reaction must be carried out in a sealed tube to effect complete solution. The reagent is used in analytical procedures for the solution of certain iron ores, phosphate rocks, slags, nickel-chromium alloys, antimony, selenium, etc., as well as for some of the less soluble sulfides; *e.g.*, those of

mercury, arsenic, cobalt and lead. It reacts with the bromide, iodide and cyanide of silver and with lead chromate to give the corresponding chlorides.

Other mixtures of oxidizing agents and complex-forming substances behave in a manner similar to that of aqua regia. The hydrochloric acid may be replaced by hydrofluoric acid or by hydrobromic acid; the nitric acid may be replaced by sodium perchlorate or perchloric acid. In the cyanide process for the recovery of gold, oxygen and potassium cyanide are used for the solution of the metal; the solution process is similar, oxygen serving as the oxidizing agent and the cyanide as the complex-forming substance. (G. W. Sr.)

AQUARELLE, the French term for water colour, used in reference both to the technique and the resultant painting. *See* Water-Colour Painting.

AQUARIUM, a receptacle or institution in which living aquatic animals or plants are exhibited or studied. The term is applied to a public exhibition of aquatic specimens with the object of instructing or entertaining the public, or for scientific study, as well as to such a household ornament as a bowl of goldfish.

Many of the principal cities of the world have or have had public aquariums, supported by either public or private funds, occasionally by both; such institutions have proved so popular that a number of private aquariums have been built, as commercial enterprises, especially in the United States. Although some aquariums engage in scientific activities of greater or less extent, their primary object is that of public education and entertainment. In another category come those aquariums which are chiefly research institutions with or without a secondary public exhibition of relatively smaller size and scope. Among the best known of the latter are those at Naples, Italy; L'Institut Océanographique, Monaco; Plymouth aquarium, Marine Biological station, Plymouth, Eng.; Scripps Institution of Oceanography, La Jolla, Calif. In still another category come temporary aquariums that have frequently been extremely popular exhibits at world's fairs and expositions. Permanent aquariums have always been popular with the public and regularly show larger attendance records than do other comparable public institutions.

Development of Public Aquariums.—The maintenance of living fishes and other aquatic organisms in captivity has a long history. The ancient Romans spent considerable effort in building huge ponds, sometimes directly connected to the sea, which they stocked with rare and valued specimens, while the Chinese of early times developed the practice of cultivating ornamental fishes suitable for keeping in small containers. The Chinese domesticated both the carp and the goldfish and from the latter they developed, by selective breeding, the forebears of the highly modified present-day domestic goldfish. The first public aquarium was opened at Regent's park, London, in 1853. Not until the art of glassmaking had reached a point where it was possible to produce large sheets of clear glass of considerable structural strength, however, did large glass-sided aquariums make their appearance. Glasses used in large-fronted aquariums are generally from 1 to 1½ in. in thickness.

The larger public aquariums suffered heavily after the onset of World War II for a variety of reasons, including those which handicapped most institutions as well as many which are peculiar to aquariums; most of those aquariums which closed or were damaged, however, were later rebuilt and reopened. With 23 public aquariums in the United States, more were in the planning stages. Others were being built in many cities throughout the temperate and tropical parts of the world. In the United States the most notable formal aquariums, as distinguished from the oceanarium type of aquariums which are a special kind of institution, are the Steinhart aquarium, San Francisco; the John G. Shedd aquarium, Chicago; and the New York aquarium, New York city. The pioneer of the oceanarium type of aquarium is Marine studios, Marineland, Fla.; Marineland of the Pacific, Palos Verdes, Calif.; and the Seaquarium, Miami, Fla., are similar. In this type of aquarium the emphasis is on very large tanks, up to 1,000,000 gallons each, in which a great variety of fishes is placed with no attempt to separate them. In the formal aquarium the kinds and types of fishes are separated and the water circulations matched to them. (C. M. Br.; C. W. C.)

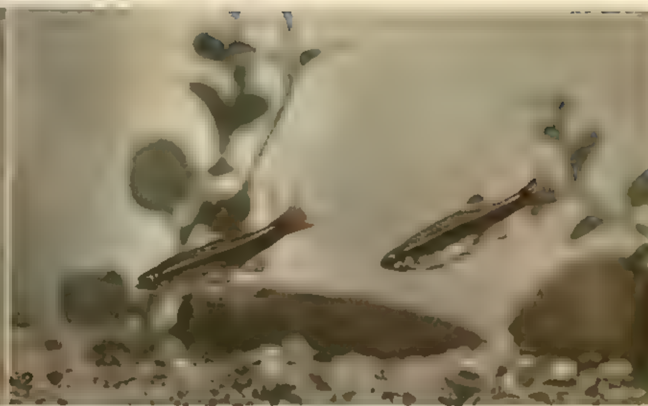
Aquarium Architecture.—The first containers specifically designed for aquatic specimens and positively identified as such were the strictly functional open-air tanks used by the Romans from at least the 2nd century to preserve and fatten fish for the market. It was not until the 18th century that the importation of goldfish into France from the orient for aesthetic enjoyment created a demand for small aquariums; and ceramic bowls, occasionally fitted with transparent sections, were produced to serve as showcases.

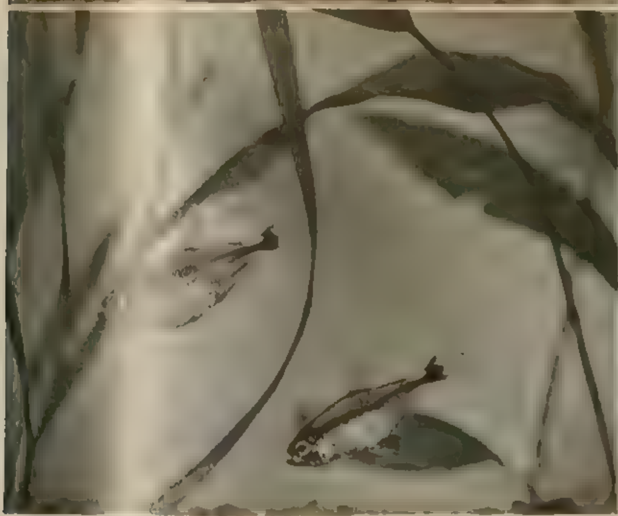
The large public aquariums in many European cities were built for the most part during the epoch of scientific romanticism, between 1850 and 1880—Berlin (1869), Naples (1873), Paris (1878). This was the time when Jules Verne's very popular novel, *20,000 Leagues Under the Sea* was published (1869), and there is no doubt that architects of aquariums were influenced by the romantic concepts of the time and made conscious effort to create the illusion that the spectator was entering into the underwater world. Thus the surface of the water was concealed and labyrinthine plans, rocky wall facings, dark colouring and low lighting were used to produce mysterious and at times terrifying effects.

More recently, as in Marineland in Florida and the New York aquarium (1956), the trend has been to emphasize the natural beauty of the specimens, and to make a sharp distinction between the water and the viewing space. (H. L. Co.)

Maintenance.—Modern aquariums are complex engineering projects involving elaborate machinery for moving and handling water and maintaining it at proper temperature and chemical constitution. In addition, there are the general problems of adaptation and diet, disease and parasitism involved in any project concerned with living creatures. In localities where there is an adequate and suitable water supply, the mechanical features are much simplified; the water is piped or pumped to the exhibition tanks and then allowed to run to waste. Fresh water is usually taken from the municipal supply, although it does not necessarily follow that potable water is suitable for fishes. The heavy chlorination practised by many municipalities for sanitary reasons is quickly fatal to fishes, and such water must first be dechlorinated. Sea water used in open circulation must be pumped from some point removed from contamination or dilution by discharging rivers. This limits the free use of sea water to those aquariums situated in places away from major cities. Even when a suitable site is available, storms may so disturb the water at the place of intake that it is unfit for use. Thus, even under the best of conditions, it is unwise for an aquarium to be dependent on exterior sources alone. When such free use of water is not possible, recourse is made to a closed system in which stored water is recirculated from a reservoir and filtered and conditioned en route. This leads to complicated mechanical operations that require constant vigilance on the part of the technical staff.

The usual arrangement of closed systems is that in which the water flows by gravity from the tank containing the specimens through a filter to a storage reservoir. Here it is lifted by a pump to an elevated distributing reservoir, from which it flows by gravity to the tank of specimens. Temperature is generally regulated in the lower reservoir by a heating or refrigerating unit thermostatically or manually controlled. Chemical treatment is generally made at this same place. Aeration, necessary to replace the oxygen consumed by the specimens and to liberate the carbon dioxide given off by them, may be undertaken at various convenient points along this circuit. In a large aquarium designed to accommodate many different kinds of organisms, both fresh-water and marine, a considerable number of such systems is frequently established. The exhibition tanks of any one system are generally arranged in parallel. Thus in actual practice there may be established three separate marine circulations of three distinct temperatures to accommodate warm, temperate and cold circulations, and a similar set for fresh water. In addition to these it may be necessary or desirable to provide brackish water of varying temperatures and fresh waters of varying degrees of acidity or alkalinity or of special chemical character. The piping and pumps necessary for such purposes must be selected with great care, and





TROPICAL FISHES KEPT IN HOME AQUARIUMS

1. Zebra fish (*Danio rerio*), 1¾ in. An active fish of the minnow family. Habitat: small mountain rivulets, Bengal, India
2. White cloud (*Tanichthys albonubes*), 1¼ in. Habitat: White Cloud mountain, near Canton, China
3. Head-and-tail-light fish (*Hemigrammus ocellifer*), 1¾ in. Habitat: British Guiana and Brazil
4. *Pristella riddlei* (no common name), 1¾ in. Habitat: northeastern South America
5. Black-banded sunfish (*Mesogonistius chaetodon*), 2 in. Habitat: coastal lowland streams, bogs, and marshes, New Jersey to Florida
6. Thick panchax (*Pachypanchax playfairi*), 3¼ in. Habitat: east Africa, Zanzibar, and Seychelles

G. J. M. TIMMERMAN FROM THREE LIONS

COMMON TROPICAL FISHES

1. Buenos Aires tetra (*Hemigrammus caudovittatus*), 3½ in. Habitat: Argentina
2. Rosy barb (*Barbus conchonius*), 3½ in. Habitat: northern India, Bengal, and Assam
3. Pearl gourami (*Trichogaster leeri*), 4 in. Habitat: Thailand and Malaya to Sumatra and Borneo
4. Angelfish or scalare (*Pterophyllum eimekei*), 6 in. Habitat: northeastern South America
5. Swordtail (*Xiphophorus helleri*), 5 in. Habitat: lowland streams of southern Mexico and Guatemala
6. Sailfin Molly (*Mollienesia velifera*), 3½ in. Habitat: coastal waters of the Yucatan peninsula

G. J. M. TIMMERMAN FROM THREE LIONS

metal is usually avoided. Brass is especially likely to produce toxic effects. Tin and titanium are perhaps the least troublesome of the metals, but hard rubber, certain plastics, glass or cement-lined pipes are generally considered most satisfactory, because they are, to all intents and purposes, chemically inert under the special conditions obtaining in aquarium water systems.

Disease and parasites are a continual threat, and there must be a constant guard against epidemics. For this reason it is considered good practice to break the various circulating systems into as small units as is practicable so that any such outbreaks may be more readily isolated. The treatment of fish ailments is difficult, and preventive measures are much more effective than attempts to cure ailing stock. Such cures are chiefly effected by immersing the diseased specimen in a solution which it can stand but which the infecting organism cannot. Selective chemicals of this kind are not always easily found or compounded.

The collection and transportation of aquatic specimens in a living state, especially if they are of considerable size, presents a variety of problems. First, they must be caught in such a manner as to be without serious damage. Transportation must be effected as rapidly as possible and with a full continuation of the immediate needs of the aquatic organism. The water in the shipping tank must be kept in suitable condition by circulation, aeration or chemical treatment throughout the trip. Smaller specimens may be shipped in sealed containers of metal or plastic about half full of water, with the remaining space being filled with air or oxygen under low pressure. Chemicals are now available to render waste products less noxious and to reduce the activity of the animals during their close confinement.

Aquariums in the Home.—A considerable variety of aquatic organisms are accommodated to life in standing water. Such aquariums present none of the difficulties inherent in the maintenance of those in which water is circulated. Caring for standing aquariums is much simpler and it is fishes that can be so accommodated that are generally to be found in the home. These form the basis of the extensive activity of private or amateur aquariists. The principles involved in the maintenance of standing aquariums are naturally similar, whether the tank is a fairly large one in a public exhibition or a relatively small one in a private living room.

A body of standing fresh water such as may be contained in a small, glass-sided aquarium contains in solution the dissolved gases of the air in proportion to their partial pressures. It is the oxygen so dissolved that is available to aquatic organisms unable to use air directly for respiration. As a fish, under these conditions, uses up the dissolved oxygen in the water, more free oxygen from the air dissolves into the water and so replaces that consumed, according to its partial pressure. From this it follows that the rate at which new oxygen dissolves into the water should be equivalent to the rate at which the fish withdraws the oxygen. If the rate is slower, the fish will eventually suffocate. Concomitantly carbon dioxide is expired by the fish. This escapes into the air through the surface of the water, tending to reach a balance with the partial pressure of that gas in the air. The escape of the exhaled carbon dioxide from the water must be at least equal to the rate at which the fish gives it off or the fish will be suffocated, not from want of oxygen but from inability to pass its continually produced carbon dioxide into the already supercharged water. Other things being equal, the rate at which these gases pass through the interface between air and water is determined by the size of that area. Thus, the greater the surface area of a body of water, the more fish—or larger fish—that body will be able to support. It is for this reason that the globular-shaped bowls with their restricted surface areas were largely abandoned. Since for observation purposes and the swimming needs of fishes there are practical disadvantages in extremely shallow aquariums, the practice of making aquariums as wide as they are high, and twice as long, has reached some degree of standardization. Aquariums with circulating water circumvent this limitation because of the opportunity of aerating the water en route. To offset the limits of the surface available in standing aquariums, air in fine bubbles may be passed through the water by means of an air pump. The surface of each tiny bubble adds to the air exposure of the water; the rising bubbles also induce a slow circulation within the tank which checks any tendency toward stratification.

In addition to exhaling carbon dioxide in the process of respiration, a fish also eliminates various body wastes, which, except for the solids, go into solution, thus modifying the chemical nature of the water in which the fish is bathed. Some species are very sensitive to certain of these wastes and are not able to survive long in standing water. Others are not so affected and many are evidently positively benefited. In household aquariums, contrary to popular notions, the water should seldom be completely changed or replenished. Generally, a glass cover should be provided to reduce evaporation and keep the fishes from jumping out.

The introduction of some form of aquatic plant life is practically essential, although the presence of plants in such an aquarium further complicates the situation. What has been mentioned about the respiration of fishes is likewise true of submerged aquatic plants. They consume dissolved oxygen and give off carbon dioxide; also, under the influence of bright light, plants consume carbon dioxide and give off oxygen while engaged in photosynthesis. This operates very well so long as light of a certain intensity falls on the plants; the animals give off what the plants can use and vice versa. Aquariums in which the plants and animals are believed to balance each other in a respiratory sense are generally referred to as balanced aquariums. However, this condition of balance is rarely attained, because when the light falls below a certain value (as at the coming of evening or on cloudy or dull days) the plants are in direct respiratory competition with the animals. Moreover, the atmosphere constantly enters the picture, affecting the exchange of gases through the water surface. Consequently it is best to have the quantities of animal and plant life so related to the surface area that they can survive indefinitely by means of gaseous exchange through the surface film. There is an additional relationship between plants and animals in such an aquarium. The waste products of the fishes form fertilizer or food for the plants and are consumed by them. It is, strictly speaking, such water that aquariists consider conditioned and most suitable for the specimens of their interest. Furthermore, dense, slow-growing plants that consume much of the waste products of relatively few fishes as fast as they are formed usually furnish the most stable and attractive small aquariums. A large variety of plants are suitable for such purposes.

Based on these principles, it is possible to maintain a large variety of fresh-water fishes with relatively little attention and inexpensive equipment. Aside from the aquariums themselves it is necessary to provide only sufficient daylight, a suitable and relatively uniform temperature and the required food. The hobby of keeping fishes in the home supports a sizable business in the importation and culturing of exotic fishes, the manufacture of aquariums and apparatus and a variety of publications devoted to the subject, as well as clubs or societies in the major cities of the world.

Most of the fishes so kept are included in the term tropical, for the vast majority of them come from the areas drained by the Amazon and adjacent lands, from the Indian peninsula and from southeastern Asia and the islands of the East Indian archipelago. These areas supply many hundreds of species of small fresh-water fishes of which 100 or so have found general favour among fish fanciers. A smaller number comes from tropical Africa. Still fewer come from the West Indian islands, Central America and the southern states of the United States.

The most popular groups of fishes usually found in the tanks of fanciers include representatives of the orders Ostariophysi, Cyprinodontes, Percomorphi and Labyrinthici, with a liberal sprinkling from the Nematognathi and a few from several other orders and suborders.

Obviously, not all the members of all these orders can be kept in domestic tanks, or in any tank, but a sufficient number have the requisite abilities to live in relatively stagnant water and close quarters, on artificial diets, and show sufficiently attractive colours or behaviour patterns to keep the fancier interested.

Aside from the attractiveness and colourfulness of the specimens and the aquarium as a whole, one of the principal interests

of the fancier centres on the breeding of the fishes available, not always from a commercial standpoint but rather as the acceptance of a challenge to find exactly what the creature requires to fulfil its life.

Actually, the breeding behaviour of many fishes is astonishingly complete in its familial aspects. This includes the mating for life of some species of cichlids, with the subsequent choosing of a site for the nest, the preparation of it, the careful placing of the eggs and the almost fanatical care and protection of them and the resulting young, even to the extent of providing a place of succour for the young in the mouths of the parents. Some go through all the nesting procedures up to the deposition of the eggs, but then pick them up and carry them until long after hatching, refusing all food until their offspring are ready to leave for good. Others build elaborate nests, using all sorts of materials which may be available, with the bubble-nest-building labyrinthine fishes such as the two-inch-long Siamese fighting fish, *Betta splendens*, using bubbles of air sealed into capsules of mucus secreted by the mouth and assembled into a raft several inches across and sometimes two inches high. The eggs are caught by the male and thrust into the mass of bubbles immediately after shedding, with the male then standing by beneath the nest until hatching is complete and the young are old enough and active enough to be kept no longer in a compact group.

In a different category is the nest building of the stickleback, not properly a tropical fish but one which is sometimes kept in small aquariums. The males of this group secrete a mucoid substance in long filaments which harden into a silklike substance. This they wrap around a small cluster of plant stalks until they have an oval mass with a hole running horizontally through it. Into this they coax a waiting female and induce her to deposit her eggs, which she then abandons to the male for further care. A single male may build three or four such nests, one above the other, for the accommodation of the eggs of as many females, all of which he then attends to, cleaning and causing streams of water to flow over them until hatching.

A simpler breeding pattern is the birth of living young to such fishes as guppies, *Lebistes reticulatus*, and the platyfishes and swordtails, *Xiphophorus maculatus* and *Xiphophorus helleri*, all small fishes of the family Poeciliidae originating in South or Central America or the West Indian islands. Fishes of this group deliver living young in broods which may number 200, at intervals of about a month or so, after they have reached maturity. Of especial interest is the fact that one fertilization is sufficient for the production of as many as eight separate broods. Such fish are able to look after themselves almost from the instant of birth and receive no parental care at all.

A relative of these species, the mosquito fish, *Heterandria formosa*, from Georgia and Florida, is the smallest live-bearing vertebrate known. This fish follows the general pattern of its relatives, but it is so small (approximately one inch long) and its young so large, relatively, that it spreads the delivery of a single brood over a period of about three weeks.

Besides attractive colours or interesting breeding behaviour, some fishes appeal to fanciers by employing odd or unusual means of finding and catching prey. The archerfish, *Toxotes jaculator*, from the brackish waters of the East Indies, has a virtually unerring ability to "shoot down" its prey, insects, by squirting drops of water at them from its mouth. The force of the drops is quite sufficient to knock a large cockroach from a leaf or twig above the water, and the accuracy often is such as to extinguish a glowing cigarette fire at 11-ft. distance. (The fish will sometimes "shoot" at the fire of cigarettes at dusk.)

Such fishes as the mudspringers or mudskippers, *Periophthalmus* species from estuaries and mud flats over a range extending from tropical West Africa to the islands of the South Pacific, always interest fanciers, for they spend more than half their time out of water, hopping about on well-developed pectoral, ventral and tail fins, catching insects on the wing. A mudspringer will even scramble up the knees of mangroves two or three feet above water level in its hunting. It returns to the water to dip first one side of its head, then the other, to replenish storage areas above the gills, and by the constant passage of water from these areas over the gills manages to keep itself alive and moist even in the hottest sun.

Odd fishes as the knifefishes, family Gymnotidae, of which the best known is the electric eel, *Electrophorus electricus*, stir the interest by the habit of swimming backward as easily as forward, and by the habit of retiring beneath the sand to sleep. Fishes as these, once they are brought to the attention of fanciers, readily command a steady market, even though many of them cannot be safely kept in the same tank, let alone bred, and there has developed a considerable trade in these fishes.

Many fishes of the live-bearing kinds are bred literally by the millions in suitable climates, such as southern Florida, with a considerable but lesser number coming from greenhouse types of hatcheries scattered throughout the United States, with a fair number being located in Germany and in England. Germany once held the lead in this type of fish culture, but lost it during World War II.

A fair number of egg-laying fishes, particularly the Amazon angelfish, *Pterophyllum eimekei*, of the family Cichlidae, and the Siamese fighting fish, *Betta splendens*, are raised in commercial establishments, but the majority of the very popular Characidae are caught wild and imported in very large numbers. This is largely a matter of economics, for commercial importers and breeders have found they can catch and import such fishes as the extremely attractive and popular neon tetra, *Hyphessobrycon innesi*, for less than the cost of feed needed to raise a brood to salable size, with no consideration given to housing or heating. Other fishes which are imported must of necessity be so, for their breeding requirements are unknown. Others are of use to fanciers only when they are small and less than breeding size, so that these too must be imported in numbers.

The feeding of tropical fishes is usually not difficult, as they will thrive on many prepared fish foods supplemented with small pond organisms such as *Daphnia*, *Tubifex* and several other tiny animals which may be cultured with a minimum of effort. Fishes take surprisingly small amounts of food, and the novice always errs in the matter of overfeeding. Unconsumed food only serves to pollute the water. Diseases and parasites are not likely to be bothersome unless an aquarium is permitted to be chilled. Chilling lowers the vitality of the specimens to a point where they are likely to become involved in various difficulties, chief of which are outbreaks of disease caused by a ubiquitous protozoan parasite, *Ichthyophthirius*, which may prove fatal. A number of other parasitic, bacterial, rickettsial and fungoid diseases have been identified, and many remedies have been suggested, including dosages with some of the antibiotic drugs. However, it sometimes happens that when these are effective they leave the way open for other organisms to attack the fish, and since the majority of illnesses which afflict fishes seem not to develop as long as the tank is kept warm enough, and proper diet is observed, and besides the fact that most disease-causative agents are unidentifiable by the layman, it seems to be better policy to keep the fishes properly rather than try to identify and treat problematical illnesses.

Prior to World War I the principal interest of U.S. aquarists centred largely on the breeding and development of exceedingly elaborate and fantastic strains of goldfish. Later, the chief interest in fancy fish rearing transferred to so-called tropical fishes breeding of which centred chiefly in Germany before 1900 but gradually spread to all parts of the world. Several domesticated forms of wild types have been developed, including the platyfish, swordtail, guppy and Siamese fighting fish, none of which, however, departs from the wild type to the monstrous degree shown by some goldfish.

Temperate- or cold-water fishes of fresh-water origin can be kept in small aquariums if the water is sufficiently cool and aerated. The usual exotic fishes kept in home aquariums, however, are provided with temperatures of from 72° to 80° F., which is too warm for many temperate-water fishes. Most of these fishes are also not adjusted to living in stagnant water, even though it is kept cool enough, and are not good candidates for domestic fish tanks. They are kept in public aquariums which have large tanks

and great volumes of water under constant circulation. Aside from such fishes as the live-bearing *Heterandira, Gambusia* and *Mollienesia* and the egg-laying *Fundulus, Jordanella* and *Chriopeops* from the warmer states of the U.S., and the Texas cichlid, *Herichthys cyanoguttatus,* there are virtually no fishes in the North American continent suitable for aquarium keeping.

The keeping of small sea-water fishes offers a constantly recurring problem to fish keepers. Many of these, usually from tropical or subtropical seas, are exceptionally brightly coloured, especially in their early stages. One difficulty is that most of them cannot stand much variation in the chemical constitution of the water in which they live, and since sea water removed from the ocean starts to deteriorate almost immediately, the fishes have only a limited life before them. Another difficulty is that most of them are used to, and require, much greater quantities of water than is available to them in domestic tanks, even if it is possible to pump the available water into and out of the tank, so that although this is linked with the other limiting factor, the deterioration of the water, it is a limiting factor in its own right.

These two factors are the main reason for the recurring failure of fanciers to keep marine fishes in domestic tanks, and these are aggravated by the difficulty of obtaining adequate supplies of good sea water. Various formulas for the manufacture of artificial sea water have been produced, all of which are based on analyses of ocean water, but artificial sea water is deficient in many elements which may or may not be necessary to the living of the fishes, and even if these could be provided there are still the organic constituents and the microorganisms of natural sea water which undoubtedly play a vital role in maintaining marine life.

For the fanciers who can afford marine fishes there are few more spectacular, however.

Related to aquarium keeping is the maintenance of fish ponds for ornamental or other purposes, and rather similar principles apply. These may be small garden pools primarily for the raising of water lilies, or larger ponds on farms for the culture of food fishes. Most governments rear fishes in hatcheries for the purpose of stocking public waters. In the United States the federal and many state governments and some private hatcheries have undertaken such work for many years. Most of the activity has centred about the various trouts and salmons, whitefishes, basses, pikes and muskellunge. Where possible the eggs are stripped from the fishes and artificially fertilized. The resulting fry are subsequently released in whatever degree of advancement is desirable or necessary.

AQUARIUS (the Water Bearer or Cupbearer), in astronomy the 11th sign of the zodiac, situated between Capricornus and Pisces. Its symbol represents part of a stream of water, probably in allusion to the fact that when the sun is in this part of the heavens (January, February) the weather is rainy. The constellation, though large, has no striking features, the brightest stars being of the third magnitude.

AQUATINT, a variety of etching (*q.v.*) in which the effect is obtained by the action of acid on the metal plate through the interstices of a porous ground. To lay the ground, powdered resin may be blown over the plate in a fine dust and then fixed by heating the plate at the back; or a solution of resin and spirits of wine may be applied evenly, so that when the spirits of wine evaporate only the particles of resin remain. Those parts of the plate which are to appear white in the print are then covered with stopping-out varnish, and the plate is immersed in acid, which bites between the particles of resin elsewhere so as to produce a granulated tone when the plate is printed. The process of stopping out is repeated and the plate bitten further to produce such deeper tones as may be required. Aquatint has frequently been used in combination with etched linework.

"HERE COMES THE BOGIE MAN." AQUATINT BY FRANCISCO GOYA (1746–1828). IN THE ART INSTITUTE OF CHICAGO

The development of the method is generally credited to J. B. le Prince (1734–81), whose earliest aquatints are of 1768; but it may have been used in some form at a considerably earlier date. F. Janinet, P. L. Debucourt and other French artists of the end of the 18th century brought the process to a technical perfection which has never been surpassed. They used it, with extraordinary skill and success, as a vehicle for printing in colour. In England in the late 18th and early 19th centuries the method was used by such artists as Paul Sandby, Thomas Malton, William and Samuel Daniell, R. Pollard and J. C. Stadler for reproducing water-colour drawings. English aquatints were not printed in colours but were usually coloured by hand. During the latter part of the 19th century the process fell into disuse, but it was revived and successfully employed in the 20th by Sir Frank Short, Théodore Roussel, Oliver Hall, W. Lee Hankey, W. P. Robins and others.

AQUAVIVA (Acquaviva), **CLAUDIO** (1543–1615), fifth general of the Society of Jesus, youngest son of the duke of Atri, was born at Atri in Italy on Sept. 14, 1543. He joined the order in 1567. His exceptional administrative ability marked him out for the highest posts. Shortly after he had terminated his brief course of studies and formation, he was appointed provincial superior of Naples and then of Rome. In 1581 he was elected general, the youngest in the history of the order. Through the fifth general congregation (1593–94) he overcame the interference of some Spanish Jesuits, supported at first by Philip II, which aimed at introducing modifications in the institute of the order and obtaining a privileged status for the Spanish provinces. His tenure of office was marked by rapid growth of the order, from about 5,000 to over 13,000. His practical legislation strengthened the society and made it more efficient in the numerous foreign missions it opened up as well as in the colleges it founded. He promoted the use of the *Spiritual Exercises* of St. Ignatius Loyola for the clergy and laymen. He encouraged the theologians and spiritual writers of the order to more profound investigation and to publication. He organized the first scholarly writing of the history of the order and the compilation of annual reports of all the provinces (*Litterae Annuae*). In the constitutions of the order, St. Ignatius had indicated only in outline the Jesuit system of education. The fourth general congregation, which had elected Aquaviva general, entrusted him with the task of drawing up a practical code of education for its now numerous schools. This work, *Ratio atque institutio studiorum,* was first published in 1586 and sent out to the various schools of the order for criticism and revision; a second edition embodying these suggestions appeared in 1591, and the definitive text of Aquaviva's generalate in 1599. This codification effected essential unity of Jesuit teaching throughout the world and allowed for local adaptation and needs. Besides his work in strengthening the order internally, he also showed himself an able ruler in guiding its external relations. He successfully furthered the apostolate of the church under eight popes from Gregory XIII to Paul V. Aquaviva died in Rome on Jan. 31, 1615. Many have considered him the order's greatest general, called by some its second founder. *See* also Jesus, Society of.

AQUEDUCT. In the broad sense of the word, an aqueduct is an artificial channel for the conveyance of water. In a more restricted sense it is often understood to mean a bridge formed in a series of arches or spans for the conveyance of water across a valley. In the usual acceptance of the word in modern engineering an aqueduct is a primary channel, or conduit, for the conveyance of water from a source to the principal point of distribution or use, subsidiary distribution conduits being generally not classed as aqueducts.

EARLY AQUEDUCTS

Tunneled conduits for springs feeding open pools or fountains were famous features of the ancient world. Hezekiah's aqueduct at Jerusalem, feeding the pool of Siloam (*c.* 725 B.C.), and the Samian aqueduct of Polycrates (*c.* 530 B.C.) are well-known examples. The experience which produced them was probably based upon the construction of irrigation or drainage channels, known early in the Greek world and in the near east and, for irrigation, employed in very remote times in Babylonia, Assyria and Egypt. The benefits of the practice of that art were no doubt taught by the annual overflow of the Nile, of the Euphrates and of the Tigris. Extensive systems of canals in conjunction with storage reservoirs were in existence in Egypt in the time of Rameses II in the 14th century B.C.

The pattern of settlement in the Mediterranean, however, marked by the choice of hilltop towns, demanded greater ingenuity than was often available, so that early water supplies normally depended upon springs, such as Callirrhoe at Athens or Pirene at Corinth. The practice of the 5th century B.C. is represented by the tunneled aqueducts with manholes at intervals described by Polybius near Hekatompylos.

Rome.—These traditions were drawn upon by Rome for its first aqueducts, Appia (312 B.C.; 10.3 mi. long) and Anio Vetus (272 B.C.; over 32 mi. long). Both were underground channels, delivering below ground in Rome near Porta Trigemina and Porta Esquilina, respectively, the deliberate choice of an underground course being governed by tactical considerations. The builder of the Appia was Appius Claudius Caecus, also the constructor of the Via Appia. His aqueduct brought water from springs situated to the east of Rome. The Anio Vetus brought water from springs in the upper Anio valley in the Apennines. It was built by contract, payment being made out of spoils obtained from the defeat of Pyrrhus. The first overhead aqueduct in the Roman Campagna was Aqua Marcia, built by Marcius the praetor (144 B.C.; 55.9 mi. long), of which 5.9 mi. lay on arches, delivering high enough to supply the Capitoline, the Caelian and the Aventine hills. Thereafter the style of conveyance varied according to the source. Aqua Tepula (125 B.C.) and Aqua Julia (40 B.C.) ran upon the arches of Aqua Marcia across the Campagna. Aqua Virgo (completed by Agrippa in 19 B.C.) ran almost entirely underground from a group of springs on the estate of Lucullus until it emerged in the Campus Martius. Aqua Alsietina (2 B.C.), built during the reign of Augustus, went underground to Trastevere. Aquae Claudia and Anio Novus (A.D. 38–52; both initiated by Caligula) returned to arches in the Campagna so as to serve the highest hills, including the Palatine. Aqua Trajana (A.D. 109) ran to the Janiculum everywhere below ground, while Aqua Alexandriana (*c.* A.D. 226) ran mainly upon arches. In A.D. 97, the nine aqueducts of Rome provided per day 38,000,000 U.S. gallons within the walls and 20,000,000 U.S. gallons outside the walls. The system was organized under the republic by contractors, who both built and ran it, and under the empire by a board of curators, with a slave staff directly supervised after A.D. 52 by an imperial procurator, new works being put to tender.

Of this great series of aqueducts long stretches of arches still stand, indicating in monumental fashion the vast extent of the ancient structures required for the conveyance of the high-level supply across the last broad depression of the Campagna to the city of Rome.

The Roman World.—Other towns of the Roman world were content with much less, according to size; but water supplies for public fountains and baths were common, private consumers being relatively few and privileged. The provinces contain many famous examples. Constantine in Africa; Segovia, Mérida and Tarragona in Spain; and the Pont du Gard in France afford splendid examples of valleys bridged. The Lyons aqueducts of Craponne, La Brévenne and Le Gier are remarkable for their inverted siphons (the course of the last containing 14) and are anticipated by the Italian Alatri (134 B.C.). Conduits of stone pipes are known in Jerusalem and of wooden pipes joined by iron collars in Roman Germany, Britain and elsewhere. Distribution chambers are well known, as at Nîmes, Minturnae or Thuburbo Maius. Overflow waters were used for driving water mills in Rome and near Arles. Supplies being normally gravitational, jet fountains or upper-floor services were rare unless pumps or water wheels raised the water to cisterns at appropriate height. Lincoln, Eng., furnishes a rare example of a main water supply which was pumped uphill.

Cost.—The political and economic aspect of ancient water supplies is of considerable interest. Roman aqueducts were normally paid for either by profit from spoils of war or by wealthy public benefactors or, later, by the imperial treasury. A simpler political version of this attitude to the problem of costs is apparent in ancient Greece, where many of the important waterworks were given to the community by autocratic rulers. Thus, while in Rome very few private consumers might be charged a water rate for their share of the public supply, neither Greeks nor Romans entertained the idea of creating the public utility company which might be financed by investors and organized as a profit-making concern based upon a planned capacity to supply a large number of individual or corporate consumers. This more modern practice is in fact closely related to the creation and development of pressure supplies with a flow of given volume related to a foreseeable number of customers. The supplies of the ancient world, though often fed from large reservoirs (for example, the *lacus Simbruinus*), were gravitational flows, running free and continuously in ducts never full. Their supply was also very inaccurately measured, since the fundamental factors of force and velocity of flow do not enter into the simple (and erroneous) calculations of Frontinus (*see* below), based upon the cross section of a standard orifice. The principal function of the ancient aqueduct was to feed public fountains or buildings, which were a gift to the community and were maintained out of public funds or endowments.

Engineering.—The ancient theory and practice of water supply were thus powerfully influenced by political and economic considerations. But on the engineering side the system of pressure supply, upon which is founded present-day ability to meet the demands of a large private consumption, was beyond the reach of the ancient hydraulic engineer, who was unaware of any means of manufacturing a high-pressure pipeline, being always mistrustful of concrete as resistant to stress. Metal pipes capable of withstanding high pressure were nonexistent. Accordingly, the ancient inverted siphon, which comes nearest to the modern pressure conduit, is furnished with blowholes, multiple pipelines of lead and every possible device to reduce pressure even though the flow of water is never impeded or held back. The impasse thus reached sheds a vivid light upon the handicaps to which ancient engineering was subject in the absence of experimental tests or regular standards.

Within these well-defined limits a very complete picture of ancient practice is given at the close of the 1st century A.D. by Sextus Julius Frontinus, supplemented by the shorter and more severely practical observations of Vitruvius, whose introduction of standard bores for pipes had been an interesting development a century earlier. Vitruvius gives detailed and pithy directions for the initial selection of supplies and for judging the quality of water. He also summarizes the various types of conduit available and describes the leveling instruments by which gradients could be worked out. His recommendations of a fall of 1 in 200 indicates a highly competent expectation of technical achievement, which in fact is often attained both in tunneled and in hillside

Pont du Gard, Nimes, France. Built by Marcus Agrippa in 19 B.C., the aqueduct consists of three tiers of semicircular arches; 155 ft. high

Arches of the Aqua Claudia, Rome, begun in A.D. 38 under the emperor Caligula (Gaius Caesar)

Roman aqueduct at Constantine, Algeria, a walled city built on a rocky plateau 500–1,000 ft. above the Rummel river

Segovia, Spain. A 2,700-ft. aqueduct built under Trajan (A.D. 53–117) and still in working order in the 20th century

Aqueduct De Los Milagros, Mérida, Sp., which carried water to the Roman city Augusta Emerita from a reservoir three miles away

sectors. Frontinus has much less to say about this technical side. His work, *De Aquaeductu urbis Romae,* is primarily intended as a political document, extolling the disinterested care and service given by himself as a senatorial *curator aquarum,* head of the water board. He illustrates the inevitable corruption rife among the working staff of slaves and their freedman supervisors; he also stresses the powerlessness of these elements of society in the face of illicit tapping of supplies by influential citizens, whose illegalities could be controlled or impertinences squashed by the reprimand of a former consul. His work is thus a justification of the senatorial contribution to imperial home government, the counterpart of the *Agricola* of Tacitus in relation to imperial provincial government.

The reforms of Frontinus show a department highly dependent upon the personal knowledge and experience of its key men. Only thus can be explained his introduction, so late in the history of the system, of record maps indicating valleys or streams bridged by the aqueducts, hillside channels where slips or washouts were likely and sectors on arches or solid underpinning. Office reference to the course at high executive level thus became possible. In his zeal for the immense practical value of his commitments, Frontinus makes a rhetorical comparison between the useless monuments of Egypt and Greece and the indispensable aqueduct, an early example of the utilitarian attitude to works of art. As for the abuses, reference has been made above to the surreptitious tapping of supplies by owners of land adjacent to the conduits. On the staff side, the standard inlet pipes to the distribution tanks were enlarged and the standard outlet pipes reduced, so that a hidden surplus might be available for illicit sale through unregistered pipes. Within the city, the mains supplying public buildings and fountains were frequently tapped both with and without staff connivance. Nothing is said of corruption in relation to raw materials, among which lead and bronze must have presented opportunities.

From his experience of the upkeep of the system, Frontinus came to the view that the workmanship of the older aqueducts was better than that of the new. But he also observed that maintenance was heaviest in the arched portions. In these, as on the Marcia-Tepula-Julia and the Claudia-Anio Novus, the later conduits were superimposed upon arches intended for one conduit only. This additional weight made flaws more likely to develop and repairs more difficult to execute, and the fault lay less in the quality of the later work than in the choice of course. The fact that there were arrangements, both permanent and temporary, for switching supplies in case of breakdown and that discrimination was made in the distribution of this or that quality of water made repairs more readily possible but not in themselves easier. The underground channels were more easily maintained, the principal disruptive element being tree roots. But the presence of regular manholes, originally the working shafts for the tunnelers, made inspection and cleaning of the limestone deposit comparatively easy.

Medieval Aqueducts.—There are a number of notable medieval aqueducts. The water supply to the cathedral city of Spoleto in central Italy is conveyed by a 13th-century aqueduct about 700 ft. long and 270 ft. high. It is noteworthy for its light and graceful proportions and for the use of pointed arches, there being ten of about 66-ft. span. Several fine examples of arched construction exist on the conduit system of Constantinople, the most noteworthy being the aqueduct of Justinian, which constitutes one of the most imposing monuments of its period. It is 720 ft. long, 108 ft. high and has two tiers of pointed arches with 55-ft. spans in the lower story and 40-ft. spans in the upper. The piers are buttressed and lightened by having small arches pierced through them at different heights. (X.)

MODERN CONSTRUCTION

The primary purposes of water supply are generally: (1) domestic water for cities or other populous communities with related sanitary requirements; (2) irrigation; and (3) hydroelectric power production, or any combination of these. For all these purposes relatively large aqueducts are usually required. Since such aqueducts often are long and costly, the communities providing them must adopt the most economical and suitable types of materials and construction for each project, and this results in a great variety of aqueducts.

Ancient aqueducts, with few exceptions, were free-flowing channels, usually built of masonry, with a continuous slight fall in the direction of the delivery point. When it was necessary to cross a valley, the channel was continued on its predetermined level and gradient on a built masonry construction, either of continuous walling or of piers and arches, until the other side was reached, when it again followed the contour of the ground. The advancement of engineering science obviated the necessity for the use on a large scale of such constructions in modern aqueducts, where the water can be conveyed when required in large, closed pipes or tunnels, flowing full under pressure and arranged within limits to follow the depressions, elevations and other topographic features of the ground.

There are, therefore, two distinct methods of flow which may be used according to the circumstances. In the one case the water flows with a free surface in a channel having a regular, gentle slope corresponding to the natural flow in a river; in the other method the water completely fills the closed conduit in which it is confined and exerts pressure on the whole of the interior surface, tending to burst the walls.

Free-Flowing Conduits.—The principal types of construction used for free-flowing conduits are: (1) open canal formed in the earth, with or without an impervious lining; (2) covered or open conduit built of brickwork, masonry, concrete or metal; and (3) tunnel, unlined or with a smooth lining of brickwork, masonry or concrete.

Free-flowing conduits take many shapes in cross section, such as rectangular, horseshoe and circular. In the case of open canals, the commonest form has a straight, flat floor and sloping sides.

Open Canals.—Open canals in Great Britain are not in favour for conveying domestic water supplies because of their liability to contamination and interference; however, they are used for this purpose in important aqueducts elsewhere. They are principally used on a large scale for conveying water to water-power stations and for the irrigation of large cultivable areas in dry countries. When the canal is unlined, the gradient must be such that the velocity does not become great enough to cause erosion of the bed or banks, say from $2\frac{1}{2}$ to 5 ft. per second, according to the firmness and cohesion of the material. Considerable loss of water from leakage may be expected with unlined canals. In lined canals velocities up to ten feet per second and sometimes much more are possible.

An unlined canal at the Humber-Arm Hydro-Electric works, in Newfoundland, to convey a minimum water flow of 5,000 cusecs (cu.ft. of water per second), was built with a bed width of 100 ft. and water depth of 21 ft. The gradient is 1 in 7,450 and the maximum velocity about three feet per second.

A concrete-lined canal for conveying water to the low head power station at Beaumont-Monteux on the Basse-Isère, in France, is 105 ft. wide on the bottom with 15 ft. maximum depth of water, side slopes of 1 to 1 and cement concrete lining 12 in. thick on floor and sides, finished with a surface rendering of cement mortar $1\frac{1}{4}$ in. thick. The lining was laid in sections with a transverse expansion joint every 23 ft. The maximum flow is 10,000 cusecs. The fall is 1 in 6,400. Many other canals, some of much larger size or length, have been built in various countries. Earth canals undoubtedly aggregate in total mileage more than all other forms of aqueducts combined.

There are a number of important materials and methods other than concrete that are successfully used in rendering canals in earth, which would otherwise leak, suitably watertight. Besides steel-reinforced concrete, which is usually much thinner than the 12 in. cited in the example above, the more important of them are: (1) Asphalt and asphalt-concrete lining, which may be in-

stalled with relatively few joints. Maintenance is a large factor with asphalt linings and an important item with concrete linings, but it is feasible where the canal may be emptied at intervals. (2) Buried asphalt membrane lining, wherein the canal is over-excavated, trimmed to smooth lines and surfaces, and a membrane of $\frac{3}{8}$- to $\frac{1}{2}$-in.-thick asphalt of rigidly specified properties is sprayed on hot without joints. After the asphalt membrane becomes cool it is covered with a selected natural material consisting of a stable mixture of earth or clay, sand and small gravel. The protective covering is generally about 18 in. thick. Buried asphalt membrane lining is usually materially lower in cost than concrete lining. (3) Selected earth or clay blanketing has been successfully used on many important canals. It is important that the blanketing consist of a suitable material, usually containing clay, sand and small gravel such that it is readily compacted into a watertight, stable mass. Where conditions demand, such blankets are as much as ten feet in thickness, especially on the side slopes of large canals where modern compacting machinery is used in placing and compacting the material. (4) Clay silting is also successfully used where conditions are favourable, and is the most economical of all methods. In the silting method, selected clay is dumped into the flowing water of the canal just above the leaky reach so that the escaping water in the leaky reach carries the clay particles into the porous formation, deposits them in the interstices thereof and clogs the porous material, thus rendering the canal watertight. The clogging process is expedited and improved if the clay used is of the bentonite type, which has the property of swelling when placed in water.

Covered Conduits.—Built aqueducts for the conveyance of domestic water supplies in Great Britain are almost invariably roofed and covered over with earth. Numerous examples have been constructed in masonry and brickwork, but concrete is generally preferred. Such conduits in suitable circumstances are more economical than pipes where the quantity of water is large, but they are applicable only where a route can be located on ground having the desired fall along a contour gradient tending in the direction of the point of delivery; pressure conduits, tunnels or flumes are built as parts of the over-all aqueduct as circumstances may require.

Tunnels.—Continued improvements in mechanical drilling, the power and reliability of explosives, the methods of handling and transporting the excavated material, and ground support and concrete lining operations contributed to a decided increase in the speed and relative economy of tunnel construction during the first half of the 20th century. The result is that tunneling is used in aqueduct construction to a much larger extent than formerly. It may be the only way for conveying water from one valley to another through a ridge which cannot be circumvented, and in other cases it may be chosen in preference to a covered conduit because of shortening of the route, greater security, lessened maintenance cost and obviation of surface damage. In very sound, unfissured rock, lining of masonry, brickwork or concrete may be dispensed with, but it is seldom that lining of the invert is omitted. In order to improve the hydraulic flow conditions it sometimes promotes economy to line the entire tunnel, even in the soundest rock. Where reliability of service under determinate hydraulic conditions is essential, a smooth lining on the whole of the wetted surface should be provided. The Loch Katrine aqueduct of the city of Glasgow, Scot., has about 19 mi. of lined tunnel of horseshoe shape with a height of nine feet and width at springing of roof arch of ten feet. It has a fall of $11\frac{1}{2}$ in. per mile and a capacity of 76,000,000 gal. per day. Tunneling on a very large scale has been used in the U.S. in aqueducts supplying certain large cities such as New York, and San Francisco and Los Angeles, Calif. A long, concrete-lined tunnel on the Catskill aqueduct for New York has a capacity of 500,000,000 U.S. gal. per day with a horseshoe-shaped cross section having a width of 13 ft. 4 in., a height of 17 ft. and an effective waterway of 165 sq.ft. The gradient is .37 per 1,000. Notable as being the longest in the world in which construction work was done wholly from the intake and outlet portals, the Alva B. Adams tunnel was built by the bureau of reclamation of the U.S. department of the interior in Colorado for transmountain diversion, irrigation and hydroelectric power purposes. It pierces the high continental divide of North America, and the mountains rise abruptly at each portal to great height above the tunnel, rendering impractical any intermediate adit for construction. It is 13.1 mi. in length, 9 ft. 9 in. finished inside diameter and lined throughout with concrete; it discharges 550 cusecs.

Pressure Conduits.—Conduits required to flow full under pressure are subject to limitations in the matter of shape and material of construction. The material must be capable of resisting tensile stresses and is most effective when disposed in circular form. The commonest types of construction are: (1) cast-iron pipes; (2) steel pipes; (3) wood stave pipes; (4) reinforced-concrete pipes or conduit; and (5) tunnel.

Cast-Iron Pipes.—Cast-iron pipes came into use about the beginning of the 19th century, as an alternative to lead and wooden pipe, for the distribution of water in towns. Cast-iron pipes are still being installed in important systems and in great quantities, but other pipes are being used more frequently in important aqueducts, principally for reasons of economy. With the rapid development of the ironfounder's craft, cast iron became available for aqueducts and has been so used in sizes up to 54-in. diameter and over. Cast-iron pipes usually have end joints of spigot-and-socket form made watertight with lead. Pipes with flanged ends to bolt together, with gaskets for watertightness, are also used. Pressure conduits of cast iron or other pipe may follow any irregular profile imposed by the route chosen, ascending here and descending there and crossing summits and hollows, provided always that none of the summits rise above the hydraulic gradient, which for a pipe of uniform diameter is approximately the straight line joining the inlet and outlet ends on the longitudinal profile. Should air collect at any of the summits, the flow will be interfered with. Air valves are therefore installed on top of the pipe at such places, and automatically discharge the air as it collects without allowing water to escape. Sluice valves fixed on scour branches at the bottom of the pipe are required at the lowest points of the pipe for the periodical discharge of any sediment which may collect there and restrict the flow. Should a burst occur on a large pipe, great damage and loss of water may occur before the water can be cut off. Automatic valves for stopping the flow when a burst occurs are desirable at the upper end of an important pipe and also at the principal summits in the case of a long pipeline.

In Great Britain pipes are secure from the effects of frost if laid with a cover of 2 ft. 6 in. of earth, whereas in more severe climates greater cover up to five or six feet as a maximum may be necessary. Where the foundation is unsatisfactory or where exceptional loads have to be resisted or special forces dealt with, as in changing direction at a bend, the pipe should be reinforced by bedding it on, or surrounding it with, concrete. In normal circumstances cast-iron pipe has long life and is generally more liable to deterioration inside than outside, so that some loss of capacity takes place with lapse of time.

Steel Pipes.—The advantages of steel pipe are its lightness, ease of handling, reliability, watertightness, security from cracking and ruptures and, not least, the fact that it can be used in much larger sizes than cast iron. Experience shows that well-coated steel pipe, when buried in normal soils, will endure for many years. Riveted steel pipe, before the advent of modern welding techniques, was for many years the manufacturing standard. There are many notable examples of riveted steel-pipe aqueduct installations, such as the pipeline from Lake Tansa for the Bombay, India, water supply and the Catskill aqueduct in New York. The diameters of the Catskill aqueduct vary from 7 ft. 4 in. to 11 ft. 3 in., and thicknesses vary from $\frac{7}{16}$ in. to $\frac{9}{16}$ in.

The successful use of steel pipe on the 13 inverted siphons, with a combined length of 49,575 ft., in the aqueduct to bring water from the high Sierras and Owens river across 250 mi. of desert to the city of Los Angeles, is an example of the economy and serviceability of this type pipe. Diameters ranged from $7\frac{1}{2}$ ft. to 11 ft., and thicknesses varied from $\frac{1}{4}$ in. to $1\frac{1}{8}$ in.

After the advent of modern welding techniques, nearly all steel

pipe was manufactured by the welding process. Such pipes are formed of steel plates bent to circular form by means of bending rolls having longitudinal joints butt-welded. The pipes are commonly made in lengths of 40 ft., and one or more plates are used to form the circle, according to the diameter. The steel plates used must be of suitable weldable quality. Frequently weldable, high-strength, alloy steel is used for welded steel pipe. Annealing of these pipe plates is not uncommon for some types of alloy material.

Joints in welded steel pipe for water-supply aqueducts are frequently welded in the field or joined by couplings with compression-type gaskets. Forged steel flanges are shop-assembled to pipe ends for connection to regulating valves and other fittings by bolting. Riveted joints are sometimes used on high-strength alloy steel pipe because of difficulty of annealing at the job site should the joints be welded. Couplings of the compression-gasket type have been used successfully for high-head penstocks where the need for annealing after welding made welded joints impractical. Couplings of this type are more economical and installation of the pipe is much easier than with riveted joints.

Great progress was made, especially after about 1940, in improving protective coatings for steel pipe. Plasticized coal-tar pitch was developed as an excellent steel-pipe protection. This coating material is centrifugally cast on the interior of steel pipe, providing a tightly bonded, water-impervious coating approximately $\frac{3}{32}$ in. thick with excellent smoothness and low friction loss. Plasticized coal-tar pitch, commonly termed coal-tar waterworks enamel, is also applied to the exterior of steel pipe by pouring and smoothing, and a bonded coal-tar–impregnated asbestos-felt wrapper is often applied over the hot coal-tar enamel in such a manner that it is bonded into the enamel. A Fiberglas pipe wrapping material is often embedded in the hot coal-tar enamel to act as a reinforcement, as steel is used to reinforce concrete. Cement mortar lining and coating is also used as a protective coating, and petroleum-base asphalt materials are sometimes used.

Steel pipe is particularly adapted to long-span, self-supporting type structures built above ground with the aid of ring girders. The ring girders are stiff, disk-shaped members which prevent distortion of the pipe at the supports. Steel pipe has the inherent beam strength required to support itself over long spans. The Shoshone river siphon built near Cody, Wyo., is an unusual ring-girder pipeline, its clear span of 150 ft. between supports being the longest unsupported span of any similar structure in the world. The diameter of the steel pipe is 123 in., and the plate thickness at the centre of the span is 1 in. The pipe has a maximum head of 155 ft. and was built with a camber to equal the computed deflection needed to make the pipe level when full of water.

Wood Stave Pipes.—Wood stave pipes, with machined staves bound at close intervals with mild steel hoops, have been found economical for low heads in districts where suitable timber is abundant and cheap. At the Humber-Arm works, Nfd., there are seven lines of such pipe, 9 ft. 6 in. in diameter, used for a maximum head of 167 ft.

A wood stave pipe 16 ft. in diameter and 1,318 ft. long to carry 3,000 cusecs was constructed in 1925 to serve the Hydro-Electric Plant No. 2 of the California-Oregon Power Co.

The use of wood stave pipe rapidly declined because of increasing cost of suitable timber, high maintenance costs and better overall economy of competitive pipes.

Reinforced-Concrete Pressure Conduits.—In the simplest reinforced-concrete pressure pipes, closely spaced hoops or helically wound continuous bands of steel, along with a system of longitudinal bars, are contained in a cylindrical concrete shell and serve to prevent bursting and fracture. The chief advantages of this type of pipe arise from small cost of maintenance, security against collapse and, frequently, saving in first cost as compared with other types. For moderate diameters, pipes may be precast in lengths up to about 24 ft., transported to the site and connected together with joints of the bell and spigot, lock joint or other special type. On the Spavinaw aqueduct for the water supply to Tulsa, Okla., there are 53 mi. of reinforced-concrete pressure conduit. Only exceptionally large conduits need to be manufactured on the site.

Precast concrete pressure pipe reinforced with steel circular and longitudinal bars and steel cylinder pipe, wherein a continuous steel cylinder is embedded in the concrete wall of the pipe, but which pipe is usually classified as concrete pipe, is assuming an increasingly important part in aqueduct construction, especially in the United States. However, many of the basic design concepts were developed and important and successful installations were made by French engineers during the latter part of the 19th century and later. Concrete pipe reinforced with circular and longitudinal bars had been built by the second half of the 20th century only in diameters up to about 15 ft. and for operation under hydraulic heads of up to about 150 ft. Embedded cylinder pipe, generally used for higher hydraulic heads, was built in diameters up to about 15 ft. and to operate under heads up to about 630 ft. The pipe is prefabricated and precast in manufacturing yards or plants, often especially constructed for a given project, and transported and placed in position by special hauling and handling equipment. It is manufactured in units up to about 24 ft. in length as circumstances warrant, and concerted attention is given to all design and construction details, especially to the joints between individual units. The type of joint that proved to be the best provides a rubber gasket compressed into an accurately formed space provided by the metal bells and spigots of the ends of the pipe units.

There were many installations of somewhat varying design and construction requirements. The U.S. bureau of reclamation had constructed by private contractors several hundred miles of this type of aqueduct, the details varying with sizes and heads, and continued to build them as the best available type in this highly competitive field, mainly in the states of California and Washington.

Precast, prestressed cylinder concrete pipe came into considerable use, especially in Europe, for important aqueducts where skilled labour was relatively plentiful and where materials, especially steel reinforcement, were relatively scarce. In this class of pipe the reinforcement for resisting the hydrostatic pressure consists of continuous, helically wound, hard-drawn steel spring wire so applied to the concrete cylinder that it retains a minimum tension of about 115,000 lb. per square inch before the pipe is placed in the trench. It appeared likely that this class of pipe would become more generally used as manufacturing difficulties were overcome and processes perfected and as reinforcing steel became relatively more costly.

Pressure Tunnels.—In hard, sound, unfissured rock, low-pressure tunnels may be unlined, but a smooth lining of concrete in conjunction with the supporting of unstable ground and the sealing of fissured places by the injection of cement through drill holes is generally necessary.

Especially interesting examples of pressure tunnels exist on the Catskill aqueduct of New York. A concrete-lined pressure tunnel, about 4 mi. long, is formed in shale deep down below the valley of the Wallkill river, thus obviating construction with pipes on the surface. It is 14 ft. 6 in. in diameter with a capacity of 500,000,000 U.S. gal. per day, and connects with free-flowing conduit at each end by means of vertical shafts. Many miles of similar tunnel have been formed in rock at a depth of 500 ft. below the streets of New York.

Another notable pressure tunnel is the Eucumbene-Tumut tunnel for transmountain diversion, power and irrigation purposes, the contract for the construction of which was awarded by the Snowy Mountains Hydro-Electric authority of New South Wales, Austr., in April 1954. Specifications included a tunnel length of approximately 14 mi. with a 21-ft. finished inside diameter; a concrete lining nominally 18 in. thick, reinforced and supplemented, as ground conditions require, by heavy reinforcing steel rods, steel support beams and roof support anchor bolts, the surrounding rock being pressure grouted with cement grout as required; operation under a maximum hydrostatic head of about 350 ft. with a maximum discharge capacity of 7,500 cusecs.

Aqueducts for City Water Supply.—The increasing distances from the place of use at which additional water supplies have to be

sought are well exemplified in the case of most of the larger towns of Great Britain, London being a notable exception. Glasgow, when its supply from the nearby Gorbals waterworks no longer sufficed, reached out into the Highlands 30 mi. away and by tunneling on a bold scale obtained an abundant and pure supply from Loch Katrine. Birmingham had to go to the Elan valley in the mountains of mid-Wales, a distance of 73 mi. Manchester went to Lake Thirlmere in Cumberland, a distance of 96 mi., to supplement the original supply obtained from Longendale, 18 mi. E. of the city. Liverpool went to the river Vyrnwy in north Wales, a distance of 68½ mi.

Some of the aqueducts for the supply of cities in the United States are colossal in comparison with the largest in Britain. Los Angeles partially obtains its water supply from the headwaters of the Owens river. The work was carried out in five years at a cost of about $23,000,000. Later Los Angeles, in collaboration with 13 other cities and communities, organized as the Metropolitan Water District of Southern California, carried out the construction of the notable Colorado river aqueduct. The main stem of this aqueduct diverts from the Colorado river at Parker dam, carries the water over several mountain ranges by pumping, and delivers it to the main terminal, Lake Matthews, 242 mi. away. Its designed capacity is 1,600 cusecs. It involved the construction of three concrete dams; five large pumping plants to lift the water a total of 1,617 ft.; 92.1 mi. of 16-ft.-diameter, horseshoe-shaped, concrete-lined tunnel; about 63 mi. of open, concrete-lined canal, 20 ft. wide and 11.71 ft. deep, with sloping sides; long reaches of horseshoe-shaped concrete cut and cover section, 16 ft. inside height and 19 ft. 5 in. inside width; and 144 inverted, cast-in-place, reinforced-concrete siphons varying from 175 to 26,400 ft. in length and operating under heads up to 153 ft. The distribution system below Lake Matthews includes several notable branch aqueducts of various construction and size. A leading branch is the aqueduct to serve the city of San Diego. This was built later than the original main-stem aqueduct and takes off from the main stem at about mile 218 and runs for about 75 mi. to deliver water to San Vincente reservoir near San Diego. The aqueduct consists predominantly of 48-in., 54-in. and 72-in. precast concrete pipe built in two adjacent, parallel and nearly identical lines. Only one line was built first because of limited funds, and it was not yet clearly demonstrated that the capacity of the two lines would be required. For static heads of less than 100 ft., steel cylinders are not embedded in the concrete pipe, but for static heads over 100 ft. and up to the maximum of 630 ft., steel cylinders are used. The 48-in. pipe is made in 20-ft. lengths and the 54-in. pipe in 16-ft. lengths. The aqueduct includes some short tunnels and reaches of welded steel pipe where the static head is the highest. The Hetch Hetchy aqueduct, designed to carry 400,000,000 gal. per day from the Sierra Nevada to San Francisco, began delivering water in 1934. This aqueduct contains two welded steel inverted siphons across the San Joaquin valley, each 47½ mi. long, operating under maximum heads of 500 ft. These unusual siphons consist of 56-in.- to 66-in.-diameter pipe of $\frac{5}{16}$-in. to ½-in. plate thickness.

New York city began work in 1937 on a $273,000,000 aqueduct to increase its water supply by 50%. The project brings water from the Delaware river by a tunnel to the existing Croton and Kensico reservoirs. The Catskill aqueduct, as noted previously, is capable of delivering 500,000,000 gal. a day to New York city.

Modern Italy furnishes an example of one of the most remarkable water-supply systems of the world in the Apulian aqueduct, which conveys water from the moist western slopes of the Apennines to an area of 8,000 sq.mi. of semiarid territory in the southeastern corner of the country. The intake is at the perennial Caposele springs, so that, as in the case of the aqueducts of ancient Rome, a storage reservoir is not required. The main conduit, which has a capacity of about 110,000,000 imperial gal. per day, is carried through the ridge of the Apennines in a tunnel 9½ mi. long and extends westward and southward for a distance of 152 mi., terminating at Taranto. Altogether about 67 mi. of the conduit were formed in tunnel, a typical cross section having a horseshoe shape 8 ft. 9 in. wide by 9 ft. 5 in. high. Water is delivered to a population of 3,000,000 in 266 communities by a system of 841 mi. of main and branch pipes and 550 mi. of distribution pipes.

Of surpassing interest in some respects is the aqueduct constructed in 1903 for supplying the gold-mining centres of Coolgardie and Kalgoorlie in Western Australia with water. The source is near the western coast, and the point of delivery is about 1,300 ft. higher in the arid heart of the country 350 mi. away. The aqueduct was formed as pressure pipe of the locking bar type (later replaced largely by welded pipe), 30 in. in diameter, with steel plate ¼ in. thick. The water is forced up, stage by stage, by means of a series of eight pumping stations with balancing tanks at each station.

High-Pressure Hydroelectric Pipes.—Of special importance are the aqueducts required to deliver water to hydroelectric stations utilizing high falls of 400 ft to 5,000 ft. or more. For such cases the fall is concentrated at the power station in as short a distance as possible. Welded steel pipe is almost exclusively used.

Two contrasting methods of installation are in use, which may be designated the Swiss and the French methods, with variations or combinations as circumstances require. In the Swiss method a heavy concrete anchorage surrounding the pipe is provided at every bend, horizontal or vertical, the pipeline being thus divided into a series of straight lengths, each of which is provided with an expansion joint near its upper end. The anchorages are designed to resist the maximum forces transmitted by the section of pipeline attached thereto. In the French method, main anchorages are provided at top and bottom only, there are no expansion joints, subsidiary intermediate anchorages are provided to hold the pipe in position and take care of the stresses produced by local variations of temperature, and generally bends and elbows are left free to spring somewhat under extremes of temperature.

A notable example of a large steel aqueduct is the Hoover (Boulder) dam combined penstock and outlet system. Noted for its height, the Hoover dam, on the Colorado river near Las Vegas, Nev., was built by the bureau of reclamation during the 1930s for irrigation, flood control, power production and other related purposes. The main penstock system consists of four 30-ft.-diameter steel pipes with various smaller branches, the 30-ft. pipes having an aggregate length of approximately 4,710 ft. The entire system is in concrete-lined tunnels in the two abutments of the dam, the 30-ft. pipe being in 50-ft.-diameter tunnels. The pipe is of welded construction, using special firebox steel having a yield strength of not less than 38,000 lb. per square inch. The system contains 45,000 tons of steel. The 30-ft. pipe operates under a maximum computed head of 619 ft. The plates have a maximum thickness of 2¾ in. The pipe sections, which vary from about 17 ft. to 23 ft. in laying length to fit alignment and related conditions, were fabricated in a large, especially constructed plant near the dam and transported to their final point of installation by special handling equipment. The sections weighed as much as 190 tons each. They were joined together by an outer butt-strap type of joint. One side of the butt strap was welded inside and out to one end of each section of pipe, thus forming the bell. The other and major portion of the butt strap was fastened to the spigot portion of the adjoining section of pipe, after the two sections were forced together by heating of the bell and by pressure, by two rows of staggered pins. The maximum-size pin is $3\frac{1}{16}$ in. in diameter by 6.73 in. long. They are countersunk on the inside end and firmly held in place on the outside end by peening of the adjacent metal of the butt strap into a groove that forms the head of the pin. There are 272 pins in each girth joint for the 30-ft. pipe. Several special and powerful tools were required to make the joints. After being otherwise completed the joints were caulked inside and out by blunt caulking tools. *See* also DAM; IRRIGATION; TUNNEL; WATER TRANSPORT, INLAND.

AQUIFOLIACEAE, the holly family, a group of dicotyledonous (having two seed leaves) plants, with 3 to 5 genera and about 300 species in the warmer parts of both hemispheres. They are all trees or shrubs and all but a few of the species belong in the large genus *Ilex*. Holly (*q.v.*), the European *Ilex aquifolium*, and allied American and Asian species are prized as ornamental shrubs, while maté (*q.v.*), yerba maté or Paraguay tea, much used in South America, is the product of *Ilex paraguariensis*.

AQUILA, the name of two early Christians.

Aquila (2nd century A.D.), a native of Sinope in Pontus (the modern Sinop, Turk.), was celebrated for a very literal and accurate translation of the Old Testament into Greek, completed probably about A.D. 140. Epiphanius preserves a tradition that he was a kinsman of the emperor Hadrian, who employed him in rebuilding Jerusalem (Aelia Capitolina), and that he was converted to Christianity, but, on being reproved for practising pagan astrology, apostatized to Judaism. He is said also to have been a disciple of Rabbi Akiba ben Joseph. Aquila's version is said to have been used in place of the Septuagint in the synagogues. The Christians generally disliked it, alleging that it rendered the messianic passages incorrectly, but Jerome and Origen speak in its praise, and Origen incorporated it in his *Hexapla*.

Aquila (fl. 1st century A.D.), a Jew from Rome, with his wife, St. Prisca or Priscilla, settled in Corinth, where Paul stayed with them (Acts xviii, 1–3). They became Christians and fellow workers with Paul, to whom they seem to have shown their devotion in some special way (in Rom. xvi, 3–5, he says that they "risked their necks" for his life).

AQUILA, in astronomy, the Eagle, sometimes named the Vulture, a constellation of the northern hemisphere, traversed by a bright part of the Milky Way, which is there divided into two branches. The stars, β, α, γ (*see* Altair), form a conspicuous group slightly reminiscent of Orion's belt. Several Novae have appeared in this constellation; in particular Nova Aquilae III, discovered on June 8, 1918, attained a brightness only slightly inferior to Sirius.

AQUILA, L', a city of central Italy, the capital of L'Aquila province and the chief town of the region of Abruzzi e Molise, lies on a hill 239 ft. above the river Aterno in the heart of the Apennines, 60 mi. E.S.E. of Terni by road. Pop. (1961) 57,265 (commune). The city walls, built in 1316 with 12 gates, are still largely extant and extend for about 4 mi. The 13th-century cathedral was rebuilt in 1711 after earthquakes; to its right is the archbishop's palace. On the highest point of the city stands the majestic castle, built in 1535, in front of which stretches a big park. The castle contains the National museum of Roman remains and artistic relics; in the basement is the geodynamic observatory. There is a university faculty in the Piazza dell' Annunziata. Near the castle park is Sta. Maria di Paganica (1308, restored). The chief church of the southern part of the city is the basilica of S. Bernardino (*c.* 1500), containing the mausoleum of S. Bernardino of Siena. To the west is the Fountain of the Rivera, dating from the foundation of the city, which has jets of water playing from 99 grotesque heads. Outside the walls is Sta. Maria di Collemaggio (1270–80). There are many palaces, a large provincial library and a municipal hospital of ancient foundation. L'Aquila is the chief point of departure for nearby Gran Sasso d'Italia (*q.v.*) and it is also a skiing centre. Radio equipment, bricks, wooden chairs, woolen cloth and chocolate are manufactured, and lacework and other crafts are practised. Many inhabitants are employed in agriculture.

After the destruction of Amiternum, Foruli and Peltunium by the Romans and later by the barbarians, the survivors built on or near the ruins. One of these settlements was to become L'Aquila when in 1229 Pope Gregory IX gave permission for a city to be built in the Acculi (Aquila) district. L'Aquila was founded by Conrad IV in 1253–54 and became an episcopal see in 1257. It belonged to Florence in the middle ages and later passed to the kingdom of Naples. L'Aquila took part in the resistance to the French invasion of 1798 and 1799, and the rebellions of the 19th century against the reactionary Neapolitan kingdom. It became part of the Italian kingdom in 1860. During World War II L'Aquila fell to Allied forces in June 1944. (U. Sp.)

AQUILEIA. Formerly a city of the Roman empire and a patriarchate of the Roman Catholic Church, Aquileia is now a village 22 mi. W.N.W. of Trieste in the Italian *regione* of Friuli-Venezia Giulia, 6 mi. inland from the head of the Adriatic.

Aquileia was founded as a colony by the Romans in 181 B.C., evidently to prevent barbarian incursions. Its rapid growth was due, however, not only to its strategic importance but also to its position at the junction of the Via Postumia with roads to Illyria, Pannonia and Noricum, especially after the Romans had succeeded, in the 1st century A.D., in establishing their rule as far as the Danube. In the 3rd or 4th century it became the capital of the administrative region Venetia and Istria.

Unsuccessfully besieged in A.D. 167 by the Marcomanni and the Quadi, the city was captured and devastated by the Huns in 452. The conquest of the Venetian mainland by the Lombards after their invasion of Italy in 568 marked the final eclipse of Aquileia's political importance, just as it sealed its decline as a commercial centre. The city became part of the Lombard duchy of Friuli.

The seat of a bishop from about the middle of the 3rd century, Aquileia became in the 5th century the metropolitan see for Venetia and Istria as well as for the outlying region north and east. According to local tradition the see had been founded by St. Mark. After the condemnation of the "Three Chapters" by Pope Vigilius in 553, Aquileia seceded from Rome, its bishop, Macedonius, adopting the title of patriarch in defiance of the pope; and the see remained schismatic when the patriarch Paulinus I fled to Grado after the Lombard invasion. When Candidianus, who was loyal to Rome, was elected metropolitan at Grado in 607, the suffragan bishops of the Lombard mainland elected an abbot John at Aquileia, and he continued the schismatic policy of his predecessors. The schism finally came to an end under the pontificate of Sergius I (687–701), when at a council at Pavia the schismatic bishops abandoned their resistance. Henceforth Aquileia and Grado were recognized as separate sees and patriarchates. The residence of the patriarch of Aquileia had been transferred at the beginning of the 7th century to Cormons for reasons of safety. From the early 8th century onward it remained at Cividale.

Aquileia's ecclesiastical importance was much enhanced by the mission of Bishop Paulinus II (d. 802) to the Avars and Slovenes, and in 811 the Drava river became the boundary between the dioceses of Salzburg and Aquileia. In the 11th century the patriarchate acquired extensive privileges and feudal dominions, largely from the German kings: Bishop Poppo, who built Aquileia's cathedral (consecrated 1031), was granted the right to coin money; and in 1077 the emperor Henry IV invested Bishop Sieghard with the county of Friuli and the march or mark of Carniola. In 1209, moreover, the emperor Otto IV enfiefed Bishop Wolfger with the march of Istria. The patriarchate remained a feudal principality until the conquest of Friuli by Venice in 1419–20 dealt the last blow to its temporal power, which the Venetians had previously done much to undermine. By the treaty of 1445 the patriarch finally acquiesced in the Venetian conquest and retained only Aquileia itself, San Vito and San Daniele. From the 15th century onward the patriarchs were always Venetians. From the end of the 16th century they resided at Udine.

Under Austrian rule the ecclesiastical jurisdiction of Aquileia was reorganized. In 1751 Pope Benedict XIV suppressed the patriarchate and created in its place the archbishoprics of Udine and Görz (Gorizia). Aquileia with its cathedral was placed under papal jurisdiction.

AQUINAS, SAINT THOMAS (Tommaso d'Aquino) (1225–1274), a Christian philosopher who developed his own original conclusions from Aristotelian premises, notably in the metaphysics of personality, creation, and a particular providence; a theologian responsible in his *Summa theologica* and *Summa contra gentiles* for the classical systematization of Latin theology; and a poet who wrote some of the most gravely beautiful eucharistic hymns in the church's liturgy, among them the *Pangue lingua* and the liturgical office for Corpus Christi. Like an Aristotle between the pre-Socratics and the Skeptics, Thomas linked the humanism of the 12th and the nominalism of the 14th centuries, more scientific in method if less engaging in style than the first, more at ease with metaphysics if less preoccupied with terms than the second. Much loved and venerated, he was canonized by John XXII in 1323 (feast day March 7) and proclaimed a doctor of the church by Pius V in 1567. His title *Doctor communis* dates from the early 14th century; the better-known but less appropriate *Doctor angelicus* was a much later style. His main position was officially confirmed by two encyclicals, Leo XIII's *Aeterni patris* (1879) and Pius XI's *Studiorem ducem* (1923). Though many modern Roman Catholic theologians do not find him altogether congenial, partly in reaction against an over-rabbinic presentation, his position in the authentic tradition of Western Christian theology is firmly established.

LIFE

Thomas Aquinas was born at the castle of Roccasecca near Aquino in the marches between the kingdom of Sicily and the States of the Church. His father was Lombard by origin, his mother was of the later invading Norman strain. Rinaldo d'Aquino, a lyric poet of the Sicilian school, may have been his brother. His people, landed nobility, were distinguished in the royal and imperial service and tragically torn in the civil strife when the Angevin supplanted the Hohenstaufen in southern Italy. Thomas grew to be a man large in physique, with a character of uncommon composure and courtesy, deep and strong in his affections for his family, friends, and religious order, very clear at expressing his thoughts yet so reticent about showing his personal feelings that he is among the most self-effacing of the great writers.

From the abbey school of Monte Cassino near his home he proceeded as arts student at the age of about 15 to the University of Naples, newly founded by the emperor Frederick II, his masters being Peter the Irishman and Martin of Dacia (*i.e.*, Denmark). There, to the formidable displeasure of his family, which had designed a high ecclesiastical career for him (even, it is said, the archbishopric of Naples), he joined the Dominicans in 1243 or 1244. They sent him north of the Alps, perhaps for a year at Paris, and certainly to Cologne (1248–52), where he continued his studies under Albertus Magnus (*q.v.*). The two formed a lifelong friendship and stood together in the controversies that were to come—the master the more extensive, if more ragged, in his learning and the more combative; the disciple the more integrated in his thought and possessing a restraint more deadly in its effect.

Thomas, who began his teaching career in 1252 as bachelor, or reader, at the college of the Jacobins (French Dominicans) in Paris, was officially admitted in 1257 to the corporation of masters in the university. This brought to a head the attack on the friars as para-ecclesiastical formations of unbeneficed clerks, licensed tramps or *vagantes*, which was launched by Guillaume de St. Amour and carried on by Gerard d'Abbeville (for this *see* further Paris, University of). Its defeat, to which the writings of Thomas contributed, was confirmed by the consolidation of his *confrères* in the universities, in Rome, and in the royal courts, particularly of England and France.

Member of a commission to organize Dominican studies, Thomas in 1259 was appointed theological adviser and lecturer to the papal curia, then the centre of Western humanism; his office of "master of the sacred palace" still survives. This was the golden period of his studies, when he assimilated Aristotle in the company of the Hellenist William of Moerbeke. Recalled to Paris in 1269 to defend his brethren and combat radical Averroism (*see* Averroism, Latin), he returned to Naples in 1272 as director of the Dominican house of studies in the university. Summoned by Gregory X to the second Council of Lyons, which was to attempt to repair the schism between Latins and Greeks, he died on his way there, at the Abbey of Fossanova in the Campagna, on March 7, 1274. Three months before he had had a mystical experience of the truth and joy beyond this life, and confessing that his earlier argumentations now seemed like so much straw in comparison he grew increasingly withdrawn; yet he continued to be at the disposal of those of every condition who came to him with their problems and doubts.

WORKS

The output of Thomas Aquinas was prodigious, a fact made possible only by the employment of secretaries for much of his later work; this goes to explain the lack of finish to his style, which is quite unadorned and deceptively sparse—the ideas are more thronging than the words. Authorities do not agree about the dates for some of his works, and those given here are in some cases provisional. The works themselves, apart from sermons, prayers, and hymns, fall into four classes: (1) those arising from his teaching course; (2) monographs; (3) commentaries on Aristotle; (4) systematic expositions of Catholic theology.

Teaching Course.—The standard theological text of the Middle Ages was Peter Lombard's *Sentences*, and Thomas' commentary on it, *Scriptum in IV libros sententiarum* (1254–56), more discursive than the *Summa*, shows his mind as a young lecturer, already anticipating some of the Aristotelian position he was later to hold with more information. There are nine commentaries on books of the Bible, consisting of *expositiones* (on Job, Jeremiah, Lamentations, part of the Gospel of John, some Pauline Epistles) written by himself; *lecturae* or *reportationes* (on Psalms, Matthew, and the rest of John) taken down by students or his chief secretary, Reginald of Piperno; and the *Catena aurea* (as it was later called), a series of comments selected from the Greek and Latin Church Fathers on the Four Gospels. Then there are the scripts of his public debates, comprising (1) ten *Quaestiones disputatae*, each forming a connected series on one topic, such as the considerable *De veritate* (1256–59), *De potentia Dei* (1265–67), and *De malo* (1269–72); and (2) 12 *Quaestiones quodlibetales*, or "quodlibets," the record of free-for-all debates on isolated topics held on special academic occasions.

Monographs.—The opuscula include: (1) three outstanding philosophical pieces, *De ente et essentia* (1254–55) and *De unitate intellectus* and *De aeternitate mundi* (both 1270). (2) Commentaries on the *De divinis nominibus* of Pseudo-Dionysius (the Areopagite; 1261), important for his aesthetic and mystical theory; on the *De trinitate* of Boethius (1258), which contains a careful treatment of the nature of theology and the interrelation of the sciences; and on the *Liber de causis* (1273) (*see* Proclus). (3) Three apologias for the friars, of which the *De perfectione* (1269) is of lasting value. (4) The *Compendium theologiae* (1273). (5) The political treatise, *De regimine principum* (1266), completed by his disciple Ptolemy of Lucca. (6) About 25 other works, some of them replies to correspondents, some of minor interest.

Commentaries on Aristotle.—Between 1266 and 1272 Thomas made close dissections of the works of Aristotle, which he read in Latin translations made directly from the Greek originals. He completed commentaries on the *Posterior Analytics*, *Physics*, *De anima*, *De sensu et sensato*, *De memoria et reminiscentia*, *Metaphysics*, and *Nicomachean Ethics*, but others were left to be completed by disciples (the *De interpretatione* or *Peri hermeneias* by Cajetan, the *De coelo et mundo* and *Politics* by Peter of Auvergne, the *De generatione et corruptione* by Thomas Sutton, the *Meteorologica* by Peter of Auvergne and possibly Jean Quidort).

Systematic Theology.—Thomas Aquinas' two most famous works are (1) the four books of the *Summa contra gentiles* (1259–64) undertaken at the request of the Dominican master general, Raymond of Peñafort, to present a reasoned account of the Christian faith to the world of Islam; and (2) the *Summa theologiae* (*theologica* by later usage; 1266–73), introduced with the modest

intention of instructing undergraduates in Catholic theology.

The majestic and well-proportioned synthesis that is the *Summa theologica* is divided into three parts: the First Part on God and the going forth of all things from him; the Second Part on the return of intelligent beings to him (Part I of the Second Part surveys in general the psychology and morality of human activity, law, and grace; Part II of the Second Part examines in particular the virtues and vices, the gifts of the Holy Spirit, the prophetical spirit, the active and the contemplative life, and the state of perfection); and the Third Part on Christ and his sacraments. This last ends abruptly during the treatise on penance, and the remainder, the Supplement, is a 14th-century compilation from Thomas' commentary on Peter Lombard's *Sentences*.

The *Summa theologica* consists of treatises composed of groups of "questions." The unit of inquiry is the article, which adopts the *sic et non* method (*see* SCHOLASTICISM: *Method*): an open question, not a thesis, is proposed, arguments are advanced for taking one side or the other, a qualifying authority or consideration is advanced, a magistral exposition follows, and the article ends with an assessment of the initial difficulties. Often the whole article must be read for the proper balance of Thomas' teaching.

THOUGHT

The early issue was Thomas' doctrine of the human soul as a single substantial form in the body—the real distinction he drew between essence and existence at the heart of created being was a later debate. It was alleged by his opponents that his thoroughgoing rationalism and even his materialism were irreconcilable with the articles of the Christian faith.

Aristotelian Background.—Western religious philosophy had developed without distinguishing itself from Christian theology; it stressed the directly divine illumination of the mind, its temper was Platonist, and its main sources were Boethius, the Pseudo-Dionysius, and, above all, Augustine (*see* PHILOSOPHY, HISTORY OF: *Patristic and Medieval Philosophy*). Aristotle had been honoured mainly as a logician until, before the middle of the 13th century, his natural and metaphysical and then his moral and political philosophy were gradually recovered, at first transmitted through Jewish and Arab writers, later translated directly from the Greek. This appearance of Aristotle's apparently self-contained system which could engage every rational interest without appeal to the Christian revelation, modified as it was by the speculations of the Muslim philosophers Avicenna and Averroës, set the schools in a ferment. Despite the opposition of the theologians the new movement gained ground in the faculties of arts, and defended itself by proposing the famous double truth theory, associated with Siger (*q.v.*) of Brabant and the Latin Averroists, that reason could reach conclusions contradictory to faith, and vice versa, without detriment to either. A later corollary was the restriction of ecclesiastical authority and the separation of church and state. Doctrines of man's inherent earthiness, of the eternity of the universe, of the triviality of the personal and particular, of an inaccessible God, and of the workings of a cosmic mind apart from individual experience affronted inherited convictions on human immortality, on creation, on the dignity of persons, on a God who spoke to men and shed his light on their minds in a world governed by a particular Providence. Such inherited convictions were defended by the Augustinian schoolmen, nobly represented by the Franciscans. These men were by no means obscurantists who subjected all knowledge to received authorities; they were pioneers in the experimental sciences and were well-versed in the thought of Avicenna and Maimonides.

Christianity and Aristotle Reconciled.—Thomas and Albertus Magnus, however, took a different course. Claiming to be better Aristotelians than the Averroists, they set themselves to prove that the new naturalism could be candidly accepted and without distortion shown to welcome Christian truth and indeed to provide terms apt for its articulation and communication. By the end of the century the whole Dominican order had swung into their position, with the exception of eccentrics, such as Durandus of St. Pourçain. They had to fight on two fronts, against both the conservative theologians and the radical Averroists, though

MANSELL—ALINARI

"THE APOTHEOSIS OF ST. THOMAS AQUINAS" BY FRANCESCO TRAINI, ALTARPIECE IN THE CHURCH OF ST. CATHERINE, PISA, 1363

Thomas' personal relations with both sides, and particularly with the lay-minded members of the arts faculties (*i.e.*, philosophers), were excellent. He had the gift of seizing the point. Thus he showed, for instance, that the question whether the universe is everlasting, which he left an open question to pure reason, was irrelevant to that of its causal dependence on a creator; and again, that the human soul was essentially embodied, and so individuated, and yet could be a spiritual substance. His philosophical interpretation of the world was no more committed to the particular physics of Aristotle, which he did not question, than his ecclesiology was to the papalism of the political canonists, to which he did not refer—a surprising fact when his eminent position at the centre of this theocratic movement is recalled. Though he cannot be compared as an empirical investigator to come of his contemporaries, for instance, Robert Grosseteste, Albertus Magnus, Robert Kilwardby, or Roger Bacon, Thomas resolutely started from the evidence of his senses without imposing on that evidence mental categories or a quasi-mathematical grid; he was so much a phenomenologist rather than an ontologist that it is difficult to appreciate how he has ever been set down as an a priori thinker.

Epistemology.—Though in direct line from Abelard, Thomas is no nominalist on the problem of universal ideas; yet, since the reference of his abstraction is always back to the individual subject as the first substance, he is no ultra-realist either. His epistemology makes no initial cleavage between being and knowing. Recognizing a kinship between all parts of reality and a consequent courteous dialogue between all branches of knowledge, his method of controlled analogy, which sees a likeness between things in

themselves quite distinct, enables him to range from low to high; his thought appears peculiarly coherent. The reason starts from sense data but can support the validity of general judgments. Anselm's ontological argument is not admitted, but the existence of God is arrived at by a posteriori inference along the celebrated "five ways" (*see* THEISM: *Summary of the Theistic Arguments and the Idea of God*). The reason can also reach a guarded knowledge of God's nature; metaphor is respected but anthropomorphism rejected; all the same Thomas' natural theology pushes beyond "negative" theology and the devout agnosticism of Maimonides which held that we can know only what God is not.

Essence and Existence.—Thomas' metaphysical distinction between essence and existence, which is variously interpreted, deepens Plato's and Aristotle's criticism of Parmenides and Heraclitus. Taking the notion of real potentiality (Lat. *potentia;* Gr. *dynamis*) into the heart of being, he establishes the status of plural substances on a basis more general than that of common sense, ethical need, or lyrical protest. Created things are real in themselves, though not of themselves, for there are no realities other than himself of which God is not the exemplar, end, and agent, working in all that they are and do. God is the first and universal cause who without violence produces their very spontaneousness and even that mode of activity called freedom, which lies fundamentally not in a power to choose good or evil but in a poise not subjected to causal determinism by any particular good. Yet under divine causality creatures are not merely occasions or instruments; they are principal causes, though secondary; and so likewise they are not merely means but true final causes, though not ultimate. Thomas sees evil as good out of place and severely argues against Manichaean dualism. His moral teaching is keyed to a world governed by purpose; "ought" presupposes "can," the right coincides with the human good, and obligation is relative to happiness (Lat. *beatitudo;* Gr. *eudaimonia*). Happiness is grasped by an act of mind, not will; Thomas recognizes the present predominance of the dialectic of love, particularly in religion, yet it is the true that defines the good. The "intellectualism" of his position can be contrasted with the "voluntarism" or affective theology of his predecessors and contemporaries. (*See* also ETHICS, HISTORY OF.)

Theology.—Above all Thomas is a theologian, though for long passages he seems to be pursuing the rational evidence, which he never twists to suit an ulterior purpose. His full doctrine, however, can be appreciated only within the dimensions of the Christian revelation. The assent of faith is directly to God himself, not to any lesser teaching authority however august; the life of the spirit lies in friendship (Lat. *caritas;* Gr. *agape*) with God, not in conformity to law properly so called. Thomas' moral theology does not delay on legalism but takes it in its stride; code justice is subordinate to a higher equity. In the history of theology he occupies a salient position with regard to grace; responding to the biblical story of God's deeds with man as progressively construed in the church's consciousness, and acknowledging an almighty justice not tempered but intensified by mercy, he propounded a strongly Augustinian doctrine of what came to be known as intrinsically efficacious grace. The point was not uncreated grace or the condition of being in God's favour, but the actual causality at work in being taken into his friendship. At the beginning of the 16th century Thomas' teaching was not well apprehended by Martin Luther, yet by the end it was the theme of exactingly conducted debates between Dominicans and Jesuits at Rome during 1598–1607 before Clement VIII and Paul V; they finished in stalemate.

Thomas draws a clear typological distinction between the natural and supernatural orders but does not regard a purely natural state as ever having existed in a historical situation. Grace offers no threat to nature; its mode of activity is entirely "connatural," and the life of grace is not to be identified with preternatural or miraculous phenomena. Thomas' dispassionate examination of transubstantiation should be set beside his eucharistic hymnody as a pointer to the many seeming contrasts he combined. Indeed he is a man for the "both," not the "either-or," who sees a continuity between life and thought, mind and sense, faith and reason, law and freedom.

CONCLUSION

Thomas was hotly criticized by traditional theologians after his death, and propositions taken from his writings were condemned by the bishop of Paris. The Dominicans, notably in England and France, however, rallied to his cause, which soon became that of his order. Thomism formed one of the schools of late medieval scholasticism, particularly strong at Louvain and Cologne. The revival of Averroism in north Italy was met by two classical expositors of Thomas' metaphysics, Francesco Sylvestri of Ferrara (Ferrariensis) and Tommaso de Vio (Cajetan), in the early 16th century. They paved the way for the baroque glory of the great Spanish school, whose members included Francisco de Vitoria, Domingo and Petro de Soto, Bartolomeo Medina, Domingo Bañez, and John of St. Thomas.

The tradition stiffened, however, and shrank to courses of ecclesiastical study until, under the aegis of Leo XIII, it was revivified and brought out from the cloister. The movement called Neo-Thomism was a major force in Roman Catholic thought for the first 30 years of the 20th century, particularly strong in its application to social questions and to problems not usually regarded as of ecclesiastical interest. The reasoned conviction, philosophical and theological, that nothing human is alien to it is its strength and will ensure its powerful continuance, less partisan perhaps and better translated into contemporary idiom, as a living body of thought in the church. *See* further THOMISM; SCHOLASTICISM.

BIBLIOGRAPHY.—*Editions:* The capital *Editio Piana* of the *Opera omnia* was published under Pius V, 17 vol. (1570–71). Its *Summa theologiae* text was reissued by the Ottawa Dominicans with excellent critical apparatus (1953). The Parma edition, 25 vol. (1852–72), in Bodoni type, and the Vives edition of Paris, 34 vol. (1871–80), in Didot, are physically readable. The standard *Editio Leonina* in progress, begun under Leo XIII in 1882, includes with the *Summa theologiae* and the *Summa contra gentiles* the classic commentaries of Cajetan and Francesco Sylvestri of Ferrara, respectively. Hymns ed. by G. M. Dreves, *Analecta hymnica*, vol. 50, pp. 583–591 (1907).

Translations: Literal Eng. trans. of the *Summa contra gentiles*, 4 vol. (1923–29), and the *Summa theologiae*, 2nd ed., 22 vol. (1921?–32) by L. Shapcote, the latter being reprinted in *Great Books of the Western World*, vol. 19–20 (1952). Eng. trans. of *Summa theologiae* with Latin text on opposite page, notes, and appendices ed. by T. Gilby, vol. 1– (1964–). Eng. trans. of *Summa contra gentiles* by A. Pegis in paperback (1955).

AQUINO, a town of central Italy in the region of Lazio and province of Frosinone, is situated on the Forme d' Aquino stream and on the Via Latina, 27 mi. (43 km.) S.E. of Frosinone by road and 81 mi. (130 km.) S.E. of Rome by road. Pop. (1961) 3,670 (commune). The old town was laid waste by Totila and abandoned for the more fertile present site, which has important Roman remains, including a triumphal arch supposed to honour Mark Antony (1st century B.C.), a doorway and a temple. The Benedictine church of Sta. Maria della Libera (1125), built on the ruins of a Roman temple, is roofless but has a fine doorway and beautiful mosaics. Natives of the town are said to include Juvenal, the Latin poet, and the emperor Pescennius Niger. St. Thomas Aquinas was born at Roccasecca castle, 3 mi. N. Aquino is on the railway from Rome to Cassino and Naples and agriculture is the chief occupation, especially the production of cereals, grapes and oil. There is a sulfur and iron spring.

The ancient town Aquinum prospered from its position on the Via Latina. During the feudal struggles Riccardo, count of Acerra, uncle of St. Thomas Aquinas, was an important figure. His son captured Roccasecca castle from Frederick II. In World War II Aquino was captured by Allied forces on June 1, 1944. (M. T. A. N.)

AQUITAINE, the name given to a region of southwestern France, still occasionally used as a geographical expression (*see* FRANCE: *Geographical Regions*). Historically it was applied at different times to different parts of the region or to the whole region according to the administrative divisions then obtaining.

In Julius Caesar's description of Gaul, Aquitania is an area bordered in the south by the Pyrenees and in the north just reaching the Garonne river. At this time Celtic Gaul extended as far south as Bordeaux and Agen, while Toulouse belonged to the Roman province of Gallia Narbonensis (*see* GAUL). In 27 B.C. when the emperor Augustus reorganized the administrative divisions in Gaul, the name Aquitania was applied to the area stretching from the Pyrenees to the lower Loire and from the Atlantic coast over Berry, the high regions of the Massif Central, Auvergne and the Cévennes. This vast territory had no single capital: Avaricum (Bourges), Limonum (Poitiers), Mediolanum Santonum (Saintes), Burdigala (Bordeaux) and Elusa (Eauze) were all of considerable importance in the administration. This was the period during which Aquitaine reached its greatest dimensions, but there is no evidence that it developed any real sense of unity.

At the end of the 3rd century A.D. an administrative reform by the emperor Diocletian brought about the division of Aquitaine into three provinces—Aquitania Prima, Aquitania Secunda and Novempopulana, with capitals at Bourges, Bordeaux and Eauze respectively (Eauze being later superseded by Auch). It was within this framework that Christianity took root in Aquitaine and the church with its dioceses and ecclesiastical provinces was organized, leading to rivalry between the archbishops of Bourges, Bordeaux and Auch for the primacy of Aquitaine. The Roman poet Ausonius writes of Aquitaine as a rich country; it produced corn and wine and exported the marble quarried in the Pyrenees.

The invasion of the Visigoths in the 5th century disorganized this Christianized Gallo-Roman province in two ways: by merging the country in a vast kingdom extending over Toulouse and Spain and by imposing Arianism in the place of Catholicism. The defeat of the Visigoths under Alaric II by Clovis at Vouillé in 507 made Aquitaine part of Frankish Gaul and resulted in the overthrow of Arianism. In the partitions of the Frankish kingdom after the death of Clovis, however, Aquitaine was the subject of disputes among Merovingian princes. In the 7th century Gascony was separated from the rest of the country, and the kingdom of Aquitaine established by Charibert did not last long. The state of disorder was made worse in the 8th century by the invasion by the Saracens. A certain Eudes (*q.v.*), or Odo, who had made himself master of Aquitaine, was obliged to call for help on Charles Martel, who exacted homage from him as the price of his support. After Charles Martel's victory over the Saracens in the battle of Tours or of Poitiers (732), however, Eudes' successors, Hunald and Waifer, resisted Frankish rule for some years, but Aquitaine was finally subdued by Charlemagne, who bestowed it as a kingdom upon his son Louis (the future emperor Louis I). It remained a kingdom under Louis' son Pepin I (814–838) and under the latter's son Pepin II (838–865), its chief towns being Toulouse, Limoges and Poitiers. Devastation by the Normans in the 9th century, however, led to political and social upheavals during which various feudal domains were established. The title of duke of Aquitaine, which had already been used by various little-known persons in the 7th century, was assumed at the end of the 9th by William I the Pious, count of Auvergne, the founder of the abbey of Cluny. In the first half of the 10th century the counts of Auvergne, of Toulouse and of Poitiers each claimed this ducal title, till it was eventually secured by William (Guilhem) I, count of Poitiers (William III of Aquitaine). The powerful house of the counts of Poitiers retained Aquitaine during the 10th and 11th centuries, endeavouring from time to time to restore to the name its former significance by extending the boundaries of the duchy to include Gascony and Toulouse. Then, on the death of the last duke, William X (William VIII of Poitiers), in 1137, his daughter Eleanor (*q.v.*), or Aliénor, united Aquitaine to the kingdom of France by her marriage with Louis VII. When Louis divorced her, however, she married in 1152 the count of Anjou, Henry Plantagenet, who two years later became king of England as Henry II. English possession of the duchy was subsequently disputed by the French kings, who won it back region by region until Guienne and Gascony (*qq.v.*) were reunited to France at the end of the Hundred Years' War. *See* BASQUE; POITIERS, COUNTS OF. *See* also references under "Aquitaine" in the Index. (RE. C.)

ARA, a constellation of the southern hemisphere (Latin *ara*, "altar"). South of Scorpio, it has three third-magnitude stars.

ARAB, originally the name of the Semitic people of the Arabian Peninsula. First generally used in this sense about the 6th century A.D., the name was more widely applied after great expansion of Arab influence in the 7th century. In contemporary usage it refers to nearly all persons (about 100,000,000 in the 1960s) whose native language is Arabic.

The article contains the following sections and subsections:

I. PRE-ISLAMIC AND TRIBAL ARABS

A. Origins

1. Traditional Accounts.—The Arabic word *'arab* (plural) probably means "those who speak clearly," as contrasted with *'ajam* ("those whose speech is indistinct"); the latter term came to be applied chiefly to Persians. In the traditional view, recorded in later Islamic times, most people of Arabia were Arabs, and comprised three groups. The first, sometimes called "lost Arabs" (*al-'arab al-bā'ida*), were extinct tribes; *e.g.*, those of Ad and Thamud mentioned in the Koran (*q.v.*). Those reckoned as descendants of an ancient patriarch named Qahtan (Qahtān) were frequently called "true Arabs" (*al-'arab al-'āriba*). Though some of them had migrated northward, it was held that they originated in southern Arabia (*see* YEMEN), and they also are known as Yemenite (Yamani). The third group recorded descent from the patriarch Adnan ('Adnān), and were distinguished as "arabized Arabs" (*al-'arab al-muta 'arriba* or *al-musta 'riba*). Considered to have been the original northern Arabs, they often are called Qaysite from one of the genealogical subdivisions. While distinctions among the groups remain relatively stable, use of names shows much variation. Sometimes the first are said to be the "true Arabs," the second *al-muta 'arriba*, "those incorporated in the Arabs," and the third *al-musta 'riba*, "those seeking to be Arabs."

Mohammed (*q.v.*) came from the northern tribe of Quraysh (Koreish), but most of his followers at Medina were from southern tribes: the Aws and the Khazraj. Later Muslim scholars tried to link the existing genealogies (of Adnan and Qahtan) with those in the Old Testament, since the Koran associates Ishmael (*q.v.*) with Mecca. Views differed, but a common theory identified Qahtan with the Joktan of Gen. 10:25 ff., and held Adnan to be a descendant of Ishmael. The Arabs were very interested in genealogical tables and had many that purported to be complete; the major early biography of Mohammed begins with one that lists 20 names between Mohammed and Adnan, 7 between Adnan and Ishmael, and 19 from Ishmael back to Adam (the latter roughly the same as the biblical names).

2. Validity of Traditional Data.—Muslim scholars did not begin to record the traditional accounts until the 8th century A.D., when an Arab empire stretched from Morocco to Central Asia. Since conditions at that time undoubtedly differed greatly from those of earlier centuries, the accuracy of the pre-Islamic genealogies has been questioned. Some Western scholars suggested that the genealogies do not preserve orally transmitted information from earlier times, but reflect tribal relations in the camp-cities of the empire during the later 7th century; but most scholars now tend to reject the view that the genealogies are mere inventions. The general consistency of this vast mass of detail is impressive, despite some discrepancies. In their earliest historical records, too, the Arabs present themselves as intensely conscious of the importance of descent (*nasab*). Also, persistence of the belief in a twofold origin (from Adnan and Qahtan) indicates some basis in reality, whatever its precise interpretation. Modern scholarship is still far, however, from producing a convincing account of Arab origins and relationships to other Semitic peoples.

3. Archaeological Evidence.—Traditional accounts reveal that some of the nomadic tribes in A.D. 600 previously had been agriculturists in the Yemen, and that they took to the desert after the dam of Ma'rib had burst. This event symbolizes the breakdown of an irrigation system on which prosperity in South Arabia depended, a failure confirmed by archaeology. Archaeologists also tend to follow W. F. Albright (*q.v.*) in holding that camels were first domesticated in Arabia between about 1500 and 1200 B.C. Camel-raiders (Midianites and Amalekites) are mentioned in Judg. 6 to 8, dating them before 1050 B.C. The domestication of camels is also linked with development of a trade route called the incense road, over which frankincense, gold, and other valuable commodities moved from South Arabia to the Mediterranean (via Gaza or Damascus). While temporary vegetation presumably had attracted owners of sheep and goats to go into parts of the desert for short periods in earlier times, camels made it possible for human beings to live there permanently. *See* also ARABIA: *History: Pre-Islamic Arabia.*

B. Culture

The great age of the nomadic Arabs immediately preceded Islam; *i.e.*, it spanned the 6th and early 7th centuries A.D. Because some of them deliberately had abandoned settled life for freedom in the desert, nomads were deeply convinced of their superiority to sedentary groups. Settled peoples in contact with the desert tended to accept this belief and to adopt many nomadic values. With exceptions in the southwest and south, Arabia was dominated by the nomadic outlook during this period.

1. Nomadic Tribal Structure.—Life in the desert depended on seasonal movements. As now, rains usually fell in the spring (*rabī'*) producing lush vegetation in the hollows of the *nafud* (sandy desert); there were no wells, but nomads could maintain life with milk from camels. When vegetation dried they moved to gravel desert where wells could be dug. Since Arabian rainfall is erratic, nomadic movements were irregular. The people grouped for defense and to share the work of herding camels.

The group was conceived as constituted by descent from a common ancestor, its subdivisions being traced to his sons and grandsons. In English the larger groups are usually called tribes and the smaller ones clans. In Arabic, the usual word for such a group of any size is Banū (modern Beni, "the sons of"). Thus Mohammed's clan of Hashim, which was also the name of his grandfather, is called in Arabic Banū Hāshim ("the sons of Hāshim") or Banū Hāshim ibn 'Abd-Manāf ("the sons of Hāshim, the son of 'Abd-Manāf"). In the early Islamic period kinship was reckoned in the male line. Some tribes in pre-Islamic times followed matrilineal kinship predominantly, practising forms of polyandry (*q.v.*) in which paternity was neglected. It is not clear how this fact of matriliny was squared with the patrilineal genealogies recorded in the early Islamic period. Islamic insistence on patrilineal descent was complemented by rules designed to ensure that paternity was known; a woman was restricted to one husband at a time, though a man might have four legal wives as well as slave concubines. Before remarrying, a divorced woman had to spend a waiting period (*idda*), usually three months and ten days, to show she was not pregnant.

Beyond full members by descent, a tribe might have persons attached to it. Women and children captured in fighting and not ransomed became tribal slaves, and could be bought and sold. Should one man ask another for protection, he could become the protector's client (*mawlā*), usually undertaking certain obligations toward his patron. When freed, a slave became a client of his former master. Where protection was temporary, a man was a protected neighbour (*jār*), presumably while he camped in the pasturelands of his protector. A man who had a more or less equal alliance with another was his confederate (*halīf*).

As now, the nominal head of a tribe was the shaykh or sheikh (*q.v.*); it was for him to give the word when the tribe was to move its camping ground. Entertainment of guests from other groups usually was the prerogative of the sheikh. His authority depended largely on his personal qualities, limited by assemblies of all adult tribal males to consider matters of policy. Sectional disputes within a tribe, if not resolved behind the scenes, could be settled in such an assembly. Intertribal differences might be referred to an arbiter (*hakam*), a man respected for wisdom, tact, and for knowledge of tribal customs. Immediate settlement was

not always desired since dispute gave excuse for the manly exercise of a *razzia* against opponents. The *razzia* (from Arabic *ghazw*), a raid aimed chiefly at driving off camels, is described as the Arab national sport.

The basis of such security as was to be had in the desert was the communally applied *lex talionis*, ". . . life for life, eye for eye, tooth for tooth . . ." (Ex. 21:23ff.). Family, clan, or tribe was held responsible for a death caused by one of its members, and any member's life might be taken in revenge. Correspondingly, vengeance was a duty of the community. Wanton injury often was prevented by the likelihood of vengeance. Under this system, an individual separated from his own group would seek to be attached to some other tribe to prevent his being injured with impunity. Tribal solidarity thus was central in desert life.

2. Sedentary Arabs.—Even apart from the southwest and south, not all inhabitants of Arabia were nomads. Scattered over most of the country were oases with subtropical agriculture; a few near the west coast had tropical vegetation.

Medina: Agriculture.—The oasis about which most is known is Yathrib, since Mohammed's time known as Medina ("the city," usually said to be a shortened form of "the city of the Prophet"). Probably of more than 25 sq.mi. (65 sq.km.) area, it produced dates chiefly, and some cereals. Here and throughout Arabia agriculture seems to have been pioneered by tribes or clans professing Judaism, some probably the descendants of refugees from Palestine, others Arabs who had accepted that faith. All were indistinguishable from their Arab neighbours except in religion. Some Arab clans already at Yathrib when the Jews arrived were in subordination to them at Mohammed's advent. However the two main Arab tribes (the Aws and the Khazraj) were later arrivals and had become more powerful than the Jews. Each tribe and clan had small forts or castles to which they could retire when attacked. Otherwise they lived on their lands. There appears to have been no concentration of dwellings anywhere in the oasis until after the coming of Mohammed. The Jewish-occupied oasis of Khaybar north of Medina was somewhat similar, though forts seem to have been fewer and larger. In other cases an oasis supported part of an Arab tribe, the remainder being nomadic. (*See* also MEDINA.)

Mecca: Trade.—Of the small settlements without oasis agriculture Mecca (*q.v.*) became by far the most important. Modern Mecca has a little agriculture, but seems to have had none in the 6th century. The original population probably was a family that controlled and served the shrine. Later known as the Ka'ba (*q.v.*), the shrine had a sanctuary area around it; the months for pilgrimage to the shrine were designated sacred. In the sacred territory and during sacred periods blood feuds were in abeyance. Members of hostile tribes met there peacefully to make Mecca a growing trade centre. By A.D. 600 its merchants held monopolistic control of the trade route from the Yemen to Gaza and Damascus; another route linked Mecca to the head of the Persian Gulf. Most Meccans then were Quraysh (Koreish). This northern Arab tribe had clans that sent their leading members to a kind of senate (*mala'*). This body lacked executive power since the *lex talionis* held, unless the head of a clan disciplined his own people. However, Mecca enjoyed a large measure of harmony; its leaders were merchants who put peaceful business considerations first. This tended to undermine nomadic customs in sedentary communities. Other centres combined trade and agriculture; *e.g.*, at-Ta'if just east of Mecca at a higher altitude, where rainfall supported some agriculture. For a time at-Ta'if was a serious trade rival, but by A.D. 600 its commercial activities had become completely subordinated to those of Mecca.

3. Nomadic Religion.—Data on pre-Islamic Arab paganism collected by Muslim scholars and recorded by Ibn al-Kalbi (d. 819) were carefully evaluated by J. Wellhausen (*q.v.*). Archaeology later provided supplementary material. The evidence indicates beliefs and practices similar to those of primitive, animistic Semitic religion elsewhere. Worship of trees and stones, occasionally of springs and wells, is frequently attested. The holy well of Bi'r Zamzam was near the Ka'ba at Mecca, and the principal object of worship there was the Black Stone (probably a meteorite regarded as the seat of a deity). The Ka'ba was a centre of pilgrimage long before Islam.

Evidently animism was passing into polytheism. Eight deities are named in the Koran, five in lxxi:23 and three in liii:19 ff. The latter (Al-lat, Al-'Uzzā, and Manat) had shrines not far from Mecca. They are sometimes called "the daughters of God" (*banāt al-lāh*), but had no connected myths or family relationships as in the Greek pantheon. The shrine of Al-lat ("the divine one") was at at-Ta'if, where she was also known simply as "the lady" (*rabba*); her seat was a square stone. Al-'Uzzā ("the strong one") had her seat in a tree at Nakhla.

Belief in spirits was widespread; *e.g.*, the *jinn* (sing. *jinnī*, the "genie" of the *Thousand and One Nights; q.v.*). Perhaps originally the forces of nature unsubdued by man, in Islamic times they were confused with Judaeo-Christian angels (*see* JINNI). Other more malevolent spirits were called *si'lāt*, *'ifrīt*, and *ghūl*. While the nomads believed in predetermination, fate was not an object of worship. Though Manāt resembles *manaya* ("fates"), she probably was an agricultural deity like Al-lat. The importance of traces of moon worship is uncertain.

Pre-Islamic Arabic poetry and stories concerning the life of Mohammed suggest that animistic and polytheistic religion had ceased to be important to the nomads and those they influenced. Attempts to base opposition to Mohammed on the old paganism had no great success. Polytheism was linked with agriculture, and much of it must have seemed irrelevant to nomads, since rainfall and seasonal changes were erratic in much of Arabia.

The effective religion of the nomads might be described as a form of humanism focused on belief in the nobility of the tribal stock. Need for solidarity in the desert left little place for individualism. Individual worth derived from the genetic membership in the clan or tribe that gave a man opportunity for noble and heroic deeds. The dominant motive was to maintain the honour of the group. Much of the virility and moral courage of Islam seems to stem from this desert outlook.

Although desert ways had lost relevance for oasis-dwellers and for thoroughly materialistic merchants based in towns like Mecca, contacts with the Byzantine, Persian, and Abyssinian empires led to admiration for monotheism. Christianity and Judaism had spread in Arabia, mainly among the settled populations. Archaeology indicates a monotheistic cult of a deity called ar-Rahman, "the merciful," in South Arabia before A.D. 400. Traces of the cult are found in the works of Muslim scholars and in the Koran. Limited evidence suggests that a number of Arabs acknowledged both the old gods (perhaps as a kind of spirit) and a supreme being (identified with Rahman and the Judaeo-Christian deity). A movement toward a nonpolitical monotheism probably arose, since Christianity was closely connected with the Byzantine and Ethiopian empires and Judaism seems to have had ties with the Sasanian Empire (*see* PERSIAN HISTORY). The Koran records some "pure" monotheists (*hanifs*), but it is unlikely that any pre-Islamic Arabs took this name. (*See* also ARABIA: *History: 6th Century* A.D.)

4. Literature.—Material poverty led nomads to use words as the chief form of artistic expression, especially oratory and poetry. Oratory is evanescent, but grounds exist for supposing that much of it approximated *saj'*, a form halfway between prose and verse. This is a peculiar feature of some later Arabic literature, usually short balancing phrases marked off by rhyme or assonance. Many fine examples of pre-Islamic poetry survive, however. The normal form is an ode (*qasīdah*) of 40 to 100 or more lines, each with the same complex metrical scheme and the same rhyme. The most famous examples are from the collection called *Mu'allaqāt* (*q.v.*); the precise meaning of the word is uncertain. Among many others preserved are the *diwans*, collected poems of individual writers (*see* ARABIC LITERATURE).

Although the *qasīdah* is said to have developed in the first half of the 6th century, earlier experimentation is presupposed; even the oldest known show maturity, perfection, and generally a standard order of topics. First came the *nasib* (prelude) in which the poet imagined a former encampment where he had had an intense, transitory love affair. He escaped from this sorrow riding

off on his camel, next compared to a desert animal such as an antelope or a wild cow. The heart of the poem either boasted of the poet's tribe including himself, satirically exposed the shame of a hostile tribe, or was a panegyric on a patron. The writer's art became manifest in his treatment of these fixed subjects, perhaps itself a reflection of attempts to function nobly in the narrow limits of desert life. As the chief art form, poetry had high social importance, exalting the tribe and its adherence to the highest values of desert nomads. In some ways the poet was comparable to the modern journalist, and the satire of an accomplished writer was greatly feared.

C. History

1. Relations with Other Civilizations.—Egyptian interest in South Arabia as a source of incense may have begun before 2000 B.C. Bedouin (*q.v.*) people are pictured in early Egyptian tombs but may represent nomads west of the Red Sea. The first literary reference to Arabs is usually taken to be an Assyrian inscription on the Battle of Karkar (*c.* 853 B.C.) in which Shalmaneser (*q.v.*) III met an alliance led by the king of Damascus, including Gindibu the Arab with 1,000 men on camels. Under Tiglath-pileser (*q.v.*) III (745–727 B.C.) two "queens of the Aribi" are reported to have paid tribute. Arabs also are noted in later Assyrian and Babylonian records, appearing as nomads (from regions between Syria and Mesopotamia and southward toward Egypt) to be kept in order by rulers of the settled lands. Some expeditions against Aribi may have been in an effort to control important trade routes.

Arabians mentioned in the Old Testament mostly seem to have been nomads from the same regions, though "the kings of Arabia" who gave gold to Solomon (II Chron. 9:14) might have come from South Arabia. "All the kings of Arabia, and all the kings of the *'ereb* that dwell in the desert" (Jer. 25:24) probably were tribal sheikhs. The prophecy of Babylon's destruction (Isa. 13:20) states "no Arab will pitch his tent there." The Arabians in Jerusalem at Pentecost (Acts 2:11) presumably were Nabataeans (*q.v.*).

Arabs also served in armies of such leaders as Cyrus, Xerxes, Alexander, Antiochus, and some Roman generals. The disastrous attempt of Romans under Aelius Gallus to march south from Petra (*q.v.*) in 25–24 B.C. was supported by a Nabataean contingent. Eventually Roman policy was to seek alliances with nomads (*e.g.*, the Ghassanids) bordering their empire who would protect against other nomads. The Sasanian Persian Empire similarly used the half-settled Lakhmids in southern Iraq (*see* Hira).

A great struggle between the Eastern Roman (or Byzantine) and the Sasanian Persian empires (ending in collapse of the Persians in A.D. 628) had been extended to Arabia early in the 6th century. Encouraged by Byzantines, an invasion of South Arabia from Ethiopia doubtless was a move against the Persians who (about A.D. 570) sent a force that occupied the Yemen. About 590 a pro-Byzantine faction in Mecca unsuccessfully tried to gain control of the city. Arab culture was influenced in many ways through commercial and political contact with the two empires. (*See* also Babylonia and Assyria: *History;* Persian History.)

2. Pre-Islamic Expansion.—The most generally accepted modern view is that various Semitic peoples flourished in the Syrian or northern Arabian desert and spread into the Fertile Crescent (*q.v.*). This seems to apply to the Arabs long before Islam; colonies of them established in Syria in the Hellenistic period (323–30 B.C.) were associated with the trade route from Petra by Damascus to Mesopotamia. Stability of Roman-Byzantine rule gradually allowed Arab pastoralists on the desert's edge to change to agriculture. Readier to accept discipline, Arabs settled in Syria substantially aided Mu'awiya, governor of Syria, in the first civil war (A.D. 656–661) of the caliphate (*q.v.*) which brought about the Omayyad dynasty. Trade led to limited Arab expansion in other directions. For example, Arab traders were on the East African coast before Islam.

D. Modern Continuation of Nomadism

Mohammed (*c.* 570–632) and subsequent expansion of the Islamic state under the caliphate had important repercussions on nomadic life. Precluded from raiding one another, tribes in alliance with Mohammed turned against non-Muslim tribes of Arabia, next against settled lands in Syria and Iraq, then farther afield. Nomads constituted much of the rank and file of the Arab armies, receiving annual stipends from the state plus a share of movable booty. Few preferred desert freedom to the luxury of new camp-cities; though they continued to exist, the nomadic tribes lost considerable manpower. Scattered notices from about A.D. 900 reflect tribal movements northeastward or through Sinai into Egypt. Although fuller information was gathered after 1700 by European explorers, centuries of obscurity preclude efforts to link all modern tribes with those of A.D. 600.

The major tribes in modern times are the 'Anaza, Shammar, the al-Murra (Murrah), the 'Ujman, and the (Banū) Khalid. The Ruwalā of the 'Anaza confederation were studied by A. Musil before World War I. All these are noble (*asil*) tribes, so-called because they never paid others for protection. Men of these tribes used to spend most of their time raiding or fighting, ensuring effective control throughout their territories. Other so-called ignoble tribes (*e.g.*, the Hutaym and Awazim) pay for protection. These may be camel- or sheep-nomads, some of whom are hired by noble tribes to look after camels. Other ignoble groups make such important specialized contributions that in fighting they are inviolate. These include the Sulaba (Sulayb, Sulubba), workers in leather, wood, and copper; and families of smiths (*sunna'*, Sunnaa), one usually attached to each noble tribe. Temporary desert visitors include general merchants (Kubaysāt) and cattle dealers ('Uqaylis). Nomads in this complex society always have tended to move toward sedentary life as government of settled regions has stabilized. Airplanes and tracked armoured cars led to stricter control of the nomads than ever before, and petroleum discoveries plunged some nomads directly into Western culture. In these modern circumstances nomadism was declining.

While it often is supposed that the Sulaba have some crusader ancestry (*see* Crusades), C. S. Coon identified them as the earliest people of the desert, probably descended from primitive hunters and representing a desert-adapted Mediterranean genetic strain. (The highlands of the Yemen also are thought to exemplify this ancient Mediterranean group relatively unchanged.) The basically Mediterranean noble tribes probably represent somewhat more admixture, though they are now largely endogamous. Sheep-herders like the Shararat seem to have mixed relatively little with other peoples; but the smiths are negroid. In southern Arabia the cattle-raising tribe of Mahra and some of their neighbours speak a peculiar form of the Semitic languages (*q.v.*); Coon suggested this indicates a pre-Arab strain akin to the Vedda (*q.v.*) of Ceylon. (*See* also Arabia: *The People;* Nomads.)

II. THE CALIPHATE (to 1924)

1. Expansion.—Between Mohammed's death (632) and the Battle of Tours (*q.v.;* or Poitiers) in 732, when Charles Martel stemmed its advance into France, the caliphate expanded west to the Pyrenees Mountains and Morocco; and east to Samarkand and the Punjab. Arabs were the spearhead; at first, instead of settling as owners of lands they conquered, they were continuously available for fighting, receiving their annual stipend from the state. Between campaigns they retired to a base or camp-city, such as Basra in Iraq and Kairouan (Qairwan) in Tunisia. By A.D. 700 their manpower was insufficient for the military needs of the Empire; non-Arabs then were permitted to become Muslims as clients (*mawali*) of Arab tribes. In this way Persians and Berbers helped continue the advance. In most provinces far more non-Arabs soon were becoming Muslims than were required as soldiers and some Arabs sought to settle down. For example, most of the relatively small number of Arabs who entered Spain (*see* Spain: *History: Moorish Spain to 1031*) stayed there for the rest of their lives. Thus the Arabs gradually lost their role as a military aristocracy. They retained most of their privileges (especially in the west) however, and small groups of them came to be found all over the domains of the caliphate.

2. Arab and Non-Arab.—Non-Arabs probably had to become tribal clients because the Islamic state essentially was regarded

as an Arab confederation. The status of client suggested inferiority, and Arabs discriminated against these Muslim converts in some ways; *e.g.*, by not fully sharing booty. Discontent, especially among Muslims of Persian origin, was a major factor in the civil war (747–750) in which the Abbasid dynasty defeated the Omayyads (*q.v.*). Persian ideas of administering an empire prevailed and men of Persian descent were influential under the Abbasids (*q.v.*). Fighting on the frontiers became a matter for professionals rather than ordinary citizens. Annual stipends were dropped, along with the idea of the state as a confederation of Arab tribes. All Muslims became basically equal when they rubbed shoulders in the streets of Baghdad.

Important differences appeared between the eastern and western provinces of the caliphate. To the east of Iraq Arabs tended to become persianized, even if the post-Islamic Persian language that appeared about A.D. 1000 borrowed freely from Arabic. From Iraq west to Spain and Morocco, however, Arabic tended to replace such local languages as Aramaic and Coptic. Some writers note a general tendency for Arabic to replace similar (*e.g.*, other Semitic) languages. Even in the eastern provinces Arabic was the usual language for jurisprudence, theology, philosophy, and other branches of higher learning.

3. Arab-Islamic Culture.—Provinces such as Iraq, Syria, and Egypt had their own highly developed art and literature. It may seem surprising that they should have come to be dominated in such fields by the lesser culture of the Arabs.

The Shu'ubiyya or Shu'ubite movement under the Abbasids toward the end of the 8th century was one factor in promoting Arab dominance. As a forerunner of this movement, Ibn-al-Muqaffa' contributed Arabic translations or adaptions of Persian prose. The Shu'ubite movement has been interpreted by Sir Hamilton Gibb as an attempt by Persian or persianized "secretaries" (*i.e.*, civil servants and administrators) to reassert Sasanian Persian values. For a time they seemed to be succeeding; their literary productions were more entertaining to the growing urban populations of Iraq than the writings of Arabic philologists and religious thinkers. Shu'ubite influence waned in the face of new prose that wedded the art and grace of persianized writings with Arabic values (*e.g.*, *see* JAHIZ, AL-).

The "secretaries" fully accepted the Arab-created Abbasid empire in which they found their livelihood. Many shared the conviction that preservation of the empire depended on maintaining the Muslim values on which warlike Arab efforts originally were based. They joined with other urban Muslims in a so-called general religious movement (a kind of pious opposition to the Omayyads). They cultivated Arabic humanities, studying Arabic grammar and lexicography as aids in interpreting the Koran. Pre-Islamic Arabic poetry was recorded to exemplify the pure use of Arabic. Genealogy and historical tradition of pre-Islamic Arabia were required properly to understand the poems. Interpretation of the Koran demanded knowledge of events during Mohammed's life. Legal decisions were guided by traditional Arabic anecdotes about Mohammed (*see* HADITH). By A.D. 850 this conception of an arabicized empire had been accepted by the Abbasids and never was reversed.

In this way the framework of Islamic culture became essentially Arabic. Nevertheless, place was given to Sasanian conceptions of government and administration; Greek philosophy, science, and medicine; some amplifications of the Koran from the Bible and from other Judaeo-Christian sources; and a little of the history of the Roman Empire. Not held valuable from an Islamic point of view, the Homeric epics and Greek tragedy were completely neglected; eventually little was retained from Greek philosophy except the system of logic.

Arab permeation of Islamic culture is manifest, regardless of the ancestry of its leaders. The philosopher of the Arabs (*see* KINDI, AL-) was so called because he was an Arab at least in the male line. The geographer Ibn Batutah (*q.v.*), born at Tangier, was known as the traveler of the Arabs. A great Muslim historian (*see* TABARI, AL-), on the other hand, was a native of Iran. Most of the great poets were Arabs, some taking pride in their membership in desert tribes (*e.g.*, *see* FARAZDAQ, AL-; JARIR IBN 'ATIYAH AL-KHATFI). The distinctive Arabic literary form of *maqama* ("assembly") was perfected by an Arab (*see* HARIRI, AL-), though its inventor (*see* HAMADHANI, AL-) seems to have been partly Persian. The belle-lettrist Abu-al-'Ala al-Ma-'arri (*q.v.*) was an Arab from Syria. Many city-dwellers of the Islamic empire were of mixed origin. The writer al-Jahiz was of Ethiopian descent largely, but his culture was basically Arabic. In short, cultural allegiance was more important than race; however, this is not to say that all non-Arabic cultures were overwhelmed. A distinctive Persian tradition continued, and a noteworthy achievement of Arabic Islam was that through its stimulation there appeared and flourished a Persian-Islamic subculture.

Only a cultural heritage as powerful and unique as the Persian could resist the subtle Arabic attractions. One expression of the Arabs' intense self-confidence was a reluctance to acknowledge borrowings from other peoples. In one tradition it is suggested that even the Lord's Prayer of the Christians was invented by Mohammed. In Islamic Spain an earlier Christian culture was largely obliterated; although most of the original conquerors had been non-Arab Berbers, Spain under the Arab Omayyad dynasty of Córdoba became more Arab than Arabia. Arab descent was so highly prized that non-Arabs invented Arab genealogies. A Christian bishop complained that his young men were neglecting Latin in their fascination with Arabic poetry. Spanish Christians who lived under Muslim rule were known as *musta 'riba*, "arabizers" (in Spanish, *Mozarabes*). (*See* also ISLAM; ISLAMIC LAW; ARABIC PHILOSOPHY; CÓRDOBA; CÓRDOBA, CALIPHATE OF; ANDALUSIA.)

4. Arab-Islamic Art.—The specific share of Arabs in the Islamic arts hardly can be isolated since Arabic values underlie most Islamic art and architecture, and since ancestry (often obscure) counted less than cultural allegiance. Primitive pre-Islamic Arab material culture offered techniques that were unsuited to higher forms of art. However, the Muslim aversion (certainly not Persian) to representing human and other animal forms in painting and sculpture does seem to come from an iconoclastic tendency in the Arab or Semitic character. There were, however, sculptures of human forms in the Arab palace of al-Mafjar near Jericho (built about 730), and mosaic representation of animals and houses in the Omayyad mosque at Damascus. Opposition to representation encouraged development of geometrical patterns that characterize Islamic art. Similarly calligraphy came to be cultivated as a decorative, nonrepresentational art, probably reflecting the Arab interest in language. Arabs themselves chiefly seem to have been responsible for the Kufic and *naskhi* forms of Arabic script.

The great accession of wealth during the Omayyad and earlier Abbasid periods produced much architecture, most commissioned by the caliphs. The caliphs probably had a general influence on buildings produced by local non-Arab craftsmen; *e.g.* the Dome of the Rock at Jerusalem. In Spain the typical Moorish arch seems to reflect Visigothic style, but something of the general conception of buildings like the mosque of Córdoba and the Alhambra at Granada may be ascribed to the continuing influence of Arabs. The so-called Mesopotamian school of painting in the 13th century was likewise largely Arab. (*See* also ISLAMIC ART; ISLAMIC ARCHITECTURE.)

5. The Ottomans.—Paradoxically, Arab expansion led to much loss of consciousness of Arab origins. Descendants of the Arab military aristocracy of Omayyad times merged with the general mass of townspeople. Relatively few people remembered their descent from Arabian tribes. Foremost were the *sayyids* and *sharifs* who prided themselves in claiming descent from the Prophet's own clan. There also were small groups here and there to whom genealogy meant much. Most of those whose first language was Arabic probably thought of themselves first as Muslims, and second as bearers of Arab culture. This tendency probably began about the 10th century A.D.

Arabic-speaking lands were conquered by the Ottoman Empire: Syria, Egypt, and Western Arabia in 1516–17, and Iraq in 1534; North Africa as far as Algeria came under nominal but ineffective Ottoman suzerainty between 1521 and 1574. This period has

been little studied (apart from a useful political history by P. M. Holt; see *Bibliography*). Arab nationalists attribute its cultural stagnation and decline to Ottoman rule, though there is no final agreement about the causes. Before the end of the 16th century central Ottoman administration began to weaken, often being unable to stop local fighting. Nevertheless Ottoman rule may be said to have kept the Islamic heartlands intact until they could deal with European influences.

In this period the language of administration was Turkish, which brought into prominence other non-Arabic cultural aspects; Ottoman scholars of any ancestry often were familiar with Persian. Arnold Toynbee wrote that the Iranic (or Perso-Turkish) civilization swallowed the Arabic culture in the 16th century A.D. Not until European ideas of nationalism began to influence subjects of the Ottomans did waning Arab self-awareness grow again, fostered by the insistence of British and U.S. missionaries on the use of Arabic language. Christian leaders of a 19th-century literary renaissance centred at Beirut contrasted themselves (to Ottoman Muslims) as Christian Arabs. Later in the 19th century an attempt to foster the concept of Ottoman nationality evoked no deep response, soon being replaced by separate Turkish and Arab nationalisms. *See* TURKEY: *History;* EGYPT: *History;* SYRIA: *History;* IRAQ: *History.*

III. MODERN TIMES

1. Contemporary Meaning of Arab.—A conference of Arab students in Brussels, Belg. (December 1938), defined as Arabs "all who are Arab in their language, culture, and loyalty (or national feeling)." Although it probably is widely accepted, such a definition posed problems in the 1940s and 1950s. Arab culture is in general Islamic, but Christians led in the Arabic literary renaissance of the 19th–20th centuries and in the Arab nationalist movement (especially in Palestine). Such people certainly are Arabs by the definition; though their language sprang from Arabic, the people of Malta just as clearly are not (*see* MALTESE LANGUAGE), since they reject Arab culture and "loyalty." Rarely, Arabic-speaking Jews outside Israel are regarded as Arabs, even by themselves in some circumstances. Arab self-awareness among Arabic-speaking Muslims has grown only gradually; there still may be some (*e.g.*, many in Mauritania) who do not think of themselves as Arabs. When the prestige of Arab sultans in Zanzibar was high, many East Africans without Arab ancestry claimed to be Arabs. After expulsion of the sultans (1964), some people there from Arab families repudiated the name. Many who still call themselves Arab may hold their culture to be Swahili–African and barely come under the definition. (*See* also TANZANIA, UNITED REPUBLIC OF: *Population* and *History.*)

2. Arab Nationalism.—The contemporary meaning of Arab developed after abolition of the caliphate (1924), more particularly after World War II. However, this recovered consciousness of being Arab has roots in the literary renaissance led by the Lebanese Arabs Nasif Yaziji (1800–71) and Butrus al-Bustani (1819–83). Their philological studies increased awareness of the beauty and power of Arabic, thus providing the vehicle for a vast literature on contemporary life. Many of the new writers hoped to contribute to the rebirth of an Arab nation. But a genuine nationalistic movement awaited greater political awareness and further acquaintance with Western thinking. Though there were earlier premonitions, the end of the 19th century came before a clear form of nationalism emerged in the writings of al-Kawakibi (d. 1902). It became effective as a political force only after World War I.

The growth of the movement began in Arabic-speaking Ottoman provinces among men aware of misrule and of the advantages of decentralization. In 1915 demands on the British by the sharif of Mecca on behalf of "the whole of the Arab nation" named the Red Sea the Arab western border, implicitly excluding Egypt. Egyptians had been virtually independent since 1805, and therefore less aware of themselves as Arabs under an Ottoman ruling class. Farther west in Tunisia, Algeria, and Morocco colonial policies of France molded education to produce Europeanized intellectuals who wrote in French. Only after 1945, when most colonial territories were moving toward independence, did Arab nationalism begin to flourish in these countries. The Arab League (or League of Arab States, founded 1945) also fostered Arab self-awareness.

These developments indicated growing membership in an Arab nation as defined earlier by the sharif of Mecca. This racial conglomerate was Arab essentially as a linguistic and cultural community. Some writers have tried to describe *'uruba*, "Arabism" or "Arabness," the essential attitude and outlook involved in being Arab; *e.g.*, Isma'il R. al-Faruqi. If Arab writers tend to exaggerate, they may be balanced by Jacques Berque's sympathetic work.

3. The Arab League.—After World War I Arab intellectuals increasingly turned to nationalism in a struggle with Western powers for fuller independence. Spurred by intellectuals agitating for an Arab nation, plans for a League of Arab States were drawn up at Alexandria, Egy. (October 1944), and the Arab League (*q.v.*) was constituted (March 1945). Continued existence of the league is a considerable achievement; the only other existing regional group with a longer history is the Organization of American States. Many Arab intellectuals are disappointed with progress toward unity; but this was not one of the league's objectives. It has increased cooperation among members and secured the region from external control. Support by the league enabled independent original members to shed vestiges of reliance on Europe, and helped others to attain independence.

The importance of the league is reflected in estimated populations (1960s) of member-states:

United Arab Republic (Egypt)	30,054,000
Sudan	13,940,000
Morocco	13,323,000
Algeria	12,093,000
Iraq	8,222,000
Saudi Arabia	8,000,000
Syria	5,120,000
Yemen	5,000,000
Tunisia	4,457,000
Lebanon	2,400,000
Jordan	1,976,000
Libya	1,677,000
Kuwait	467,000
Total	106,729,000

Potential members of the league in 1967 were Aden and other members of the Federation of South Arabia, the Persian Gulf amirates and sheikhdoms, and perhaps Mauritania.

More than 500,000 Arabs (Muslim, Christian, and Druze) lived in Israel, the victor in a brief Arab-Israeli clash in June 1967. Possibly a third of the 3,307,000 inhabitants of Chad were Arabic-speaking.

Arab minorities live in Iran on the shores of the Persian Gulf, on the east coast of Africa, and in the Americas (especially the U.S.). One major non-Arab minority is found in the southern Sudan; others include the Berbers in North Africa and the Kurds of Iraq. Numbering about 1,200,000, the latter discontentedly aspired to political autonomy, perhaps along with fellow Kurds in Turkey and Iran. Berber-speakers (more than 10,000,000) showed little response to French attempts to develop their sense of community. Many also spoke Arabic and, as arabization continued, Berber political separatism grew more unlikely. Non-Arabs in southern Sudan are divided into many tribes, have no common language, and probably will continue to be arabized.

4. Discovery of Petroleum.—Formation of the Anglo-Persian Oil Company (1909) eventually led to a rich strike (1927) near Kirkuk, Iraq. Petroleum was found in Bahrain (1932), in Al Hasa province of Saudi Arabia (1935), and in Kuwait (1938). After 1945 producing wells appeared in other parts of the Persian Gulf and in Arabic-speaking North Africa. Yielding vast quantities annually, the Middle East in the 1960s was reckoned to have nearly two-thirds of earth's petroleum reserves.

Control of the Middle East with its escalating petroleum production was a prominent factor in international strategy before 1939. During World War II the supply to Anglo-European allies was partly interrupted, requiring supplementary petroleum from the Americas. Postwar control of Middle Eastern wells was in the forefront of calculations by the great powers. Aware of its

bargaining potential Mohammed Mossadegh (*q.v.*) nationalized (1951) production in Iran. Such events heightened respect of oil companies toward Arab desires for independence. Middle East producers lost substantial advantage as new sources were tapped elsewhere.

Petroleum revenues have transformed only a few Arab countries. Although the desert sheikhdom of Kuwait rapidly attained the highest per capita income in the world, deposits are far from equally divided among Arab countries. The Arab League has failed to generate economic cooperation for the region as a whole, which benefits only slightly from the new wealth. Among the primary beneficiaries, Iraq has kept a portion of the revenues for national development; Kuwait (*q.v.*) has enlightened educational and medical programs underway; but Saudi Arabia has a reputation for lavish spending on luxuries for the few. Wise use of petroleum resources and royalties might permit rapid development of Arab countries, but favourable political conditions seldom obtain. (*See* PETROLEUM: *History*). *See* also references under "Arab" in the Index.

ARAB, SHATT AL, the channel formed by the junction of the Tigris and Euphrates rivers of Iraq. The course of the Tigris is clearly defined, but the lower Euphrates spreads into a very shallow lake (Hawr al Hammar), while a channel (Old Euphrates) runs a little to the north of Hawr al Hammar to join the Tigris at Al Qurnah.

The river pattern is probably of relatively recent origin, and divergent views exist regarding the mode of origin of the whole system (*see* IRAQ). From southwest Iran the Shatt al Arab receives the Karun river. Possibly at one time the Tigris and Euphrates entered the Persian gulf by another inlet, the Khawr az Zubayr, and the Karun alone reached the sea by what is now the lower part of the Shatt al Arab.

At Basra the Shatt al Arab is about 40 yd. wide, gradually opening to 600–800 yd. below the confluence with the Karun river near Mohammerah and to about one-half mile in width at Al Faw. Most of the banks are lined with palm groves and the rising tide ponds back fresh river water which floods the groves, providing a remarkable natural irrigation. Another unusual feature is that for about 60 mi. above Al Faw the frontier between Iraq and Iran follows the left (eastern) bank of the Shatt (with one small exception near Al Faw), bringing the entire waterway within Iraq. This has led to a number of disputes. Extensive dredging after 1930 provided a 22-ft. channel at Basra and a 30-ft. one at Al Faw —an indication of the growing importance of the Shatt al Arab as an outlet both for Iraq and Iran. (W. B. FR.)

ARABESQUE, in 16th-century France a word meaning merely "Arabian," but by 1611 translated in R. Cotgrave's *Dictionary* as "rebesque work, a small and curious flourishing." In fact the word arabesque, which should properly have been used to characterize ornament that followed the Muslim law forbidding the representation of the human figure, came to be the appellation of the Renaissance imitations of classical rinceaux which at first seem to have recalled to their finders the graceful scrolls of the Muslim style. (The term has also come to mean a ballet position. *See* BALLET: *Technique of Ballet.*)

The Roman stucchi (plaster modelings), which were revealed to Italian humanists in such remains as the *tombe latine* ("Roman tombs"), were used as models for stonework by Filippo Brunelleschi at the Badia di Fiesole, which, though not finished until 1462, was designed earlier, and inspired the painted decoration by Giulio Romano and the pupils of Raphael in the *loggie* (open galleries) of the Vatican. Similar compositions adorn the walls of the Villa Madama at Rome and the palaces at Mantua. Considerably rationalized, they inspired the design of such decorative sculptures as the Martinengo tomb and the façade of Sta. Maria dei Miracoli at Brescia. They inspired much of the plateresque (*q.v.*) style that gave the delicacy of silver work to the architecture of northern Italy and, later, of Spain. Traveling craftsmen brought them to France; the application of sculptured panels of arabesque design to what is essentially a Gothic structure is the first impress of Renaissance style in France. Native engravers such as Jacques Androuet du Cerceau and Marc Duval did much to naturalize them. Arabesques soon passed from the field of architectural decoration into other spheres; *e.g.*, the decoration of majolica at Urbino, of armour at Milan, of tapestry at Florence and of illuminated manuscripts at Mantua. Such Renaissance arabesques maintained the classical tradition of median symmetry, freedom in detail and heterogeneity in ornament, but there was no slavish copying. Cameolike scenes of modern life in the *loggie* include a medallion of Raphael's pupils working at the very designs that the medallion adorns.

Henry Peacham, writing in 1612, admirably describes such compositions:

> The forme of it is a generall, and (as I may say) an unnatural or unorderly composition for delight sake, of men, beasts, birds, fishes, flowers etc., without (as we say) rime or reason, for the greater variety you show in your invention, the more you please . . . You may, if you list, draw naked boyes riding and playing with their papermils or buble-shels upon Goates, Eagles, Dolphins etc., the bones of a Ram's head hung with strings of beads and Ribands, Satyres, Tritons, Apes, cornu-copias, Dogs yoakt, and drawing cowcumbers, Cherries, or any kind of wild traile or vinet after your owne invention, with a thousand more such idel toyes, so that herein you cannot be too fantastical.

The word arabesque thus came to take a wider range and to mean any elegant ornament upon the surface of verse or prose.

ALINARI

PAINTED ARABESQUE IN THE LOGGIA OF RAPHAEL IN THE VATICAN

Arabesques became familiar to craftsmen who might never have visited Italy through the engravings of such designers as Nicoletto Rosex da Modena and such northern engravers as Lucas van Leyden.

As the humanist conception of classical style passed into the three dimensions of the baroque, such surface ornament gradually lapsed from favour. It was little used during the 17th century and the *rocaille* style fulfilled the same purpose in the first half of the 18th century. Then the discovery of a new series of Roman "arabesques" at Herculaneum and Pompeii, followed by their publication in engravings, revived the style, especially in France. In 1757 the comte de Caylus published his *Recueil de peintures antiques* and by 1770 engraved models for arabesques were once more being published in Paris.

The French reliefs and paintings in the style by such masters as J. Rousseau are, perhaps, the most beautiful arabesques ever produced. The formality of Directoire and Empire design gradually brought the fashion to an end.

In England there was a parallel development of arabesque. Horace Walpole wrote that the discoveries at Herculaneum "testify that a light and fantastic architecture of a very Indian air" was in common use in Roman houses, and it was not long before Robert Adam was applying it to English use. His Etruscan manner, first used about 1775 in Lord Derby's London house and at Osterley, represents a new version of arabesque, purified by a severer taste. By 1780 T. Leverton's decorations of the saloon at Woodhall park showed a pseudo-Grecian version of the style.

Nonrepresentational ornament inspired by the east had, too, its place in Renaissance design, but it was termed not arabesque but Moresque. Arabic forms and inscriptions had long been familiar in Sicilian and north Italian textiles and in the Spanish decorative arts of Mudejar (*q.v.*).

It seems rather to have been from Ottoman Turkey that a revived fashion for such ornament reached 16th-century Italy and inspiration seems to have come not from textiles but from damascened metal work. Benvenuto Cellini tells how he imitated such metal work, but that he introduced birds and animals among the stylized foliage. Far more often the conventional leafage was retained, though it might be a little classicized and the frets and knots and symmetry of its basic lines were little changed. Its essentially surface character seems to have attracted great pictorial artists; Albrecht Dürer and Hans Holbein, the Younger, as well as a crowd of lesser men, designed in the style. It first appeared in Venetian metal work about 1520, and gradually merged into the strapwork and flower decoration current about 60 years later.

ARABIA (Jazirat al Arab, "Island of the Arabs"), the name applied to the peninsula in the extreme southwest of Asia, bounded by the Red Sea on the southwest, the Gulf of Aden and the Arabian Sea on the south, and the Gulf of Oman and the Persian Gulf on the northeast. Geographically the peninsula and the Syrian Desert merge in the north with no clear line of demarcation, but the northern boundaries of Saudi Arabia and Kuwait are generally taken as marking the limit of Arabia there.

In shape the peninsula forms a trapezoid whose symmetry is flawed by the eastern projection of Muscat and Oman. The total area is about 1,000,000 sq.mi. (2,590,000 sq.km.). The length, bordering the Red Sea, is approximately 1,200 mi. (1,900 km.) and the maximum breadth, from Yemen to Oman, 1,300 mi. (2,100 km.). The larger political divisions are the kingdom of Saudi Arabia, the republic of Yemen, the sultanate of Muscat and Oman, and the Protectorate of South Arabia with the colony of Aden. Seven British-protected Trucial States lie on the Persian Gulf and the Gulf of Oman, along with the independent amirate of Kuwait and the British-protected sheikhdoms of Bahrain and Qatar on the Arabian side of the Persian Gulf.

Geographically Arabia is linked to Africa by the Sinai Peninsula, whose terrain and inhabitants are similar to those of neighbouring Arabia, though territory held by Jordan and Israel at the head of the Gulf of Aqaba intrudes between the two. The Red Sea affords the usual avenue of approach to Africa. Arabia has easy access to the rest of Asia by both land and sea. The island of Socotra (*q.v.*), though lying about 220 mi. (350 km.) off the mainland, belongs politically and ethnographically to Arabia.

This article contains the following sections and subsections:

I. GEOGRAPHY

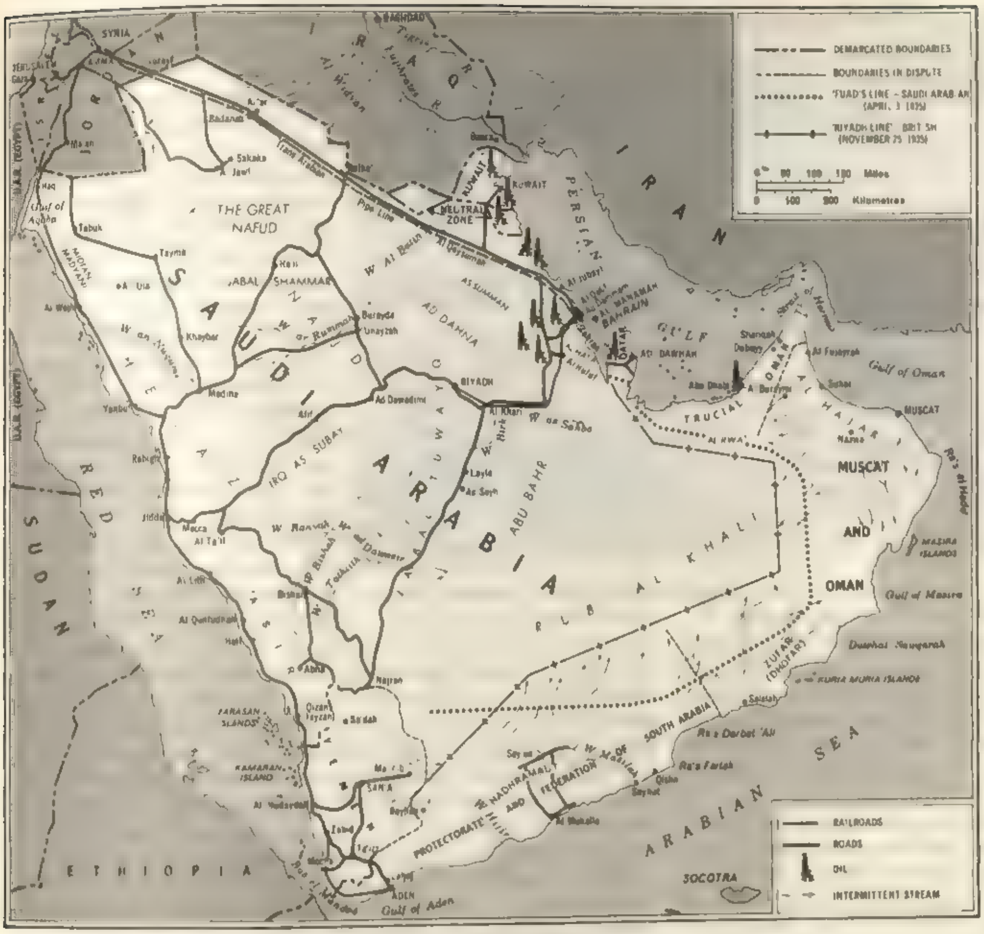
Arabia may be described as a great plateau sloping gently eastward from a mountain range running along the whole length of its west side. At the southeast extremity the character of the peninsula is disturbed by the lofty excrescence of Al Jabal al Akhdar of Oman. Except for Yemen, Oman, and numerous scattered wadis or valleys in the western range, it is a land remarkable for its aridity and barrenness.

1. Geology.—Geomorphologically the bulk of Arabia consists of two main provinces, the Arabian shield in the west and sedimentary areas dipping away from the shield to the northeast, east, and southeast into the great basin consisting of lower Iraq, the Persian Gulf, and the eastern part of the Rub' al Khali. The eastern edge of the shield curves eastward from the head of the Gulf of Aqaba to a point about midway across Arabia and then trends southwestward and southward to the Yemen mountains. Many extinct volcanoes overlie the shield; their eruptions, which ceased seven centuries ago, produced the broad black lava beds (*harrahs*) characteristic of the western Arabian landscape.

The sedimentary areas, not nearly as ancient as the shield, represent the deposits of seas which once reached it and at times partially covered it. The sedimentary strata have been extensively eroded. The harder members, more resistant to erosion, now stand up as westward-facing escarpments following the curve of the shield. The sedimentary province consists primarily of limestone, together with much sandstone and shale. The first deposits are early Paleozoic, which in eastern Arabia may be almost six miles (9,700 m.) below the surface. In the Jurassic and Cretaceous limestone occur oil and gas accumulations at depths of two miles or less. Some of the limestone strata take in rainfall at outcrops in the western highlands and carry it underground to the Persian Gulf lowland.

The Yemen (Yaman) mountains are physiographically very different from those of the shield, even though composed of similar rocks. In Yemen, geological confusion replaces the relative simplicity of the regions farther north. The main range along the southern coast is basically sedimentary in origin. The Oman ('Uman) mountains are geologically more closely related to the ranges of Iran than to their counterparts in Arabia, despite the sea barrier on one hand and the land link on the other. The sea is only about 30 mi. (48 km.) wide at the Strait of Hormuz.

2. Regional Geography.—Mountain walls shut off the interior of Arabia from the sea on three sides. From these lofty walls the interior slopes gradually down into the basin whose lowest portion is filled by the Persian Gulf, the descent being eastward from Hejaz (Al Hijaz) and 'Asir, northward from the southern coast and westward from Oman. The interrelationship of the regions may be emphasized by reviewing in order (1) the western wall, the core of which is the Arabian shield, and the various stages of the descent from this crest into the basin; (2) the southern wall; and (3) the Oman wall, geologically the least intrinsic part of Arabia. As the individuality of Yemen forbids its being bracketed



THE ARABIAN PENINSULA

improvements have been made to the port of Yanbu' (Yenbo) for Medina. Qizan (correctly, Jayzan) is the district capital of Tihamat 'Asir. Islands are particularly numerous along the southern part of the coast, where the Farasan Archipelago lies, and coral reefs are common.

In the Midian hinterland the sandstone plateau of Hisma has an elevation of about 4,000 ft. (1,220 m.). South of it are great *harrahs* such as 'Uwayrid, while others ring Medina. Tongues of lava, lapping over the mountains, descend almost to the coast. The sand plain of Rukbah, traversed by the highway from Mecca to Najd, unrolls south of Harrat Kashb. Among the *harrahs* east of Mecca is one surrounding the mountains of Hidn (Hadn), the traditional border area between Hejaz and Najd. (*See* also HEJAZ; 'ASIR.)

Najd.—The western part of Najd (Nejd), known as Upper Najd, lies within the Arabian shield with an average elevation of 4,000 ft.; the eastern part falls within the sedimentary province with Riyadh (Ar Riyad), near the eastern edge, having an elevation of 1,950 ft. (594 m.). The principal drainage of Najd ("highland") consists of a number of eastward-flowing wadi systems which carry water only seasonally. In the north, Wadi ar Rummah rises in Harrat Khaybar and runs past the twin cities of Buraydah (Buraida) and 'Unayzah (Anaiza) to lose itself in the Ad Dahna' sands, after which it reappears under the name Al Batin and goes on to the vicinity of Basra (Al Basrah) in southern Iraq. In the centre a number of valleys, including Wadi Hanifah, empty into Wadi as Sahba' in the Al Kharj district; after struggling through Ad Dahna', Wadi as Sahba' is submerged in the sands of Al Jafurah. In the south the wadis of Ranyah, Bishah, and Tathlith converge out of the highlands on Wadi ad Dawasir (named after the Dawasir tribe), which sinks away in the Rub' al Khali.

The parallel ranges of Aja' and Salma tower above the plateau to form Jabal Shammar (named after the Shammar tribe), the northernmost district of Najd. Just south of the Mecca-Riyadh road is the Jabal an Nir. East of the Hejaz highlands lies 'Irq as Subay' (named after the tribe of As Subay'), the largest sand desert within the shield.

The broad mountain-studded plateau gives way in central and eastern Najd to a series of escarpments curving from north to south along the contour of the shield: Al Khuff, Jilh al 'Ishar, Jabal Tuwayq, and Al 'Armah. Of these the longest and highest is Jabal Tuwayq, which with its length of 800 mi. (1,290 km.) constitutes the backbone of the most densely settled part of Najd. The steep western face of Tuwayq, rising about 800 ft. (240 m.) above the plains to the west, is pierced by half a dozen wadis, of which the most spectacular is Wadi Birk, a tributary of Wadi as Sahba'. West of Tuwayq a series of sand deserts (*'irqs* and *nafuds*) forms an almost continuous link between the Great Nafud and the Rub' al Khali; these also conform to the curve of the shield.

The district of Al Aflaj on the gentle eastern slope of Tuwayq and the neighbouring district of Al Kharj contain pools remarkable only in a lakeless land such as Arabia. (*See* also NAJD.)

The Great Nafud (*An Nafud*).—The second largest sand desert

with either the western range or the southern, it may be considered separately as a hinge between the two. Unless otherwise noted, all regions belong politically to Saudi Arabia.

Hejaz and 'Asir.—A virtually unbroken mountain chain runs the length of the peninsula above the Red Sea. The stretch from Aqaba to a point about 200 mi. (320 km.) S of Mecca is called Hejaz (*al hijaz*, "the barrier"), and the stretch from there to Najran near the Yemen border has in modern times acquired the name of 'Asir (from the name, meaning "difficult," of a prominent highland tribal confederation). In places the chain consists of two parallel ranges separated by a plateau, with the lower range closer to the coast. In Midian (Madyan), the northernmost part of Hejaz, the peaks have a maximum elevation of nearly 9,500 ft. (2,890 m.). The elevation decreases to the south, with an occasional upward surge such as Jabal Radwa west of Medina (Al Madinah). Wadi al Hamd, drawing water from the Medina basin on the inner side of the chain, breaks through the mountains to reach the Red Sea, though the main road to Medina from the coast takes a shorter course via the village of Al Musayjid. Another pass leads to Mecca and At Ta'if in the highlands. The mountains become higher again in 'Asir, where some peaks rise to more than 9,000 ft. The passes there are particularly difficult. A *harrah* descending from the mountains and reaching the sea near Hali long formed the natural southern boundary of Hejaz. The high plateau of 'Asir, coming within the area watered by the Indian Ocean monsoon, is more fertile and populous than rural Hejaz. Abha is the highland district capital.

The Red Sea coast plain is constricted throughout its length, attaining its greatest widths, well under 50 mi. (80 km.), south of Medina and south of Mecca. The name Tihamah, used for the whole plain, is sometimes subdivided into Tihamat al Hijaz and Tihamat 'Asir. There are no natural harbours adequate for large vessels, but the many inlets are well suited for sailing craft. A modern port for Mecca was constructed at Jidda (Juddah), and

KHAFS DAGHRAH, ONE OF THE MANY OASES SCATTERED THROUGHOUT THE ARABIAN PENINSULA

in Arabia, the Great Nafud, marks the northern limit of Najd. Lying just beyond the shield, it occupies an area of about 26,000 sq.mi. (67,300 sq.km.). Its sands almost reach the oasis towns of Tayma' (Taima) in the west, Al Jawf and Sakaka in the north, and Ha'il in the south. The sands are gradually moving toward the southeast, where they enter either 'Irq al Mazhur, the first of the deserts lying west of Tuwayq, or Ad Dahna'.

The Great Nafud contains few watering places, and the central crossing is not easy for either camels or motor vehicles. When the dunes are covered with annuals after the winter and spring rains, the desert is a favourite grazing ground for the flocks of the nomadic Bedouin herdsmen.

Northern Arabia.—From the northern edge of the Great Nafud the old highway to Jordan and Syria runs northwest through Wadi as Sirhan, a depression rather than a true wadi, about 200 mi. (320 km.) long and 1,000 ft. (305 m.) below the adjacent plateau. Among the settlements there are Qurayyat al Milh (the Little Salt Villages). East of Wadi as Sirhan are wide *harrahs* and chert plains belonging to the southern part of Al Hamad, the Syrian Desert. The basin containing the Great Nafud is rimmed on the north by escarpments, down the northern slope of which run Al Widyan or Widyan 'Anazah (the wadis of the tribe of 'Anazah), to empty into the Euphrates Valley; among the largest of these are 'Ar'ar and Wadi al Khurr. The wadis are crossed by the Trans-Arabian Pipe Line (Tapline), which transports oil from Saudi Arabia to the terminal at Sidon (Sayda) in Lebanon; after its construction in 1950 its companion road became the main artery for traffic to Jordan and Syria, the frontier post in Saudi Arabia being Turayf.

Ad Dahna'.—The Ad Dahna' belt, separating Najd from eastern Arabia, is a sand stream moving slowly over 800 mi. (1,290 km.) from the Great Nafud to the Rub' al Khali. Usually no more than 50 mi. (80 km.) wide, Ad Dahna' is crossed in several places by motor roads and in one place by the Ad Dammam–Riyadh railroad. The sands, often reddish in colour, vary greatly in form; particularly in the central stretches, long parallel ridges rise to heights of about 150 ft. (45 m.), while some dunes are three times that height. Ad Dahna' also provides pasture in winter and spring. In 1957 the Khurays oil field was discovered beneath its sands.

The Rub' al Khali.—The largest uninterrupted sand desert in the world, the Rub' al Khali covers an area estimated at about 230,000 sq.mi. (595,700 sq.km.). The name Rub' al Khali (Empty Quarter) is not commonly used by the Bedouins who roam there; they call it simply Ar Ramlah (the Sand). Only parts of it are truly empty; through the central portion a string of watering places makes the north–south crossing not too formidable for nomads, and camel routes lead into other areas. Traversed for the first time by a westerner, Bertram Thomas, in 1930–31, the desert has been intensively explored by the Arabian American Oil Company since 1950.

Some areas may have droughts of more than ten years' duration, while others sometimes have thunderstorms or high summer humidity. In the west the gravel plains of Rayda' and Abu Bahr separate the Rub' al Khali from the southern end of Ad Dahna', while another gravel plain, Al Jaladah, lies within the Rub' al Khali. What appears to be a northern extension of the Rub' al Khali, Al Jafurah, is regarded by the Arabs as an independent desert. Southeast of Qatar the sands give way before the vast salt flat of Sabkhat Mati, which runs north about 60 mi. (nearly 100 km.) to the Persian Gulf coast. East of Mati the oasis hamlets of Al Jiwa' (Liwa') lie among the dunes on the desert's northern fringe. The largest dunes of the Rub' al Khali are in the far east, where heights of well over 500 ft. (150 m.) are reached and sand ridges extend for more than 30 mi., with salt flats as the usual floor in between. Along the Oman edge is the large salt flat of Umm as Samim, whose surface is unusually soft in places. Near the southeastern corner of the Rub' al Khali is situated the comparatively well-watered area of Muqshin, much frequented by Bedouins. In the southwest, sand ridges running in a straight line reach a length of 150 mi. (240 km.).

Most of the Rub' al Khali falls within Saudi Arabia, but eastern portions of it, including the oases of Al Jiwa', are in dispute between Saudi Arabia and the British-protected Trucial State of Abu Dhabi. The sultanate of Muscat and Oman also has claims in this vicinity.

The Persian Gulf Lowland.—A low-lying region follows the Arabian shore of the Persian Gulf from Kuwait round to the Oman mountains at the mouth of the gulf. The gravel plain of Ad Dibdibah lies inland southwest of Kuwait. Adjacent to Ad Dahna' is the low plateau of As Summan, between which and the coast scattered hills rise a few hundred feet. Broad patches of sand occur here and there and salt flats are numerous. The Persian Gulf on this side provides no good deep-draft natural harbours, but many inlets offer shelter to sailing craft, and modern ports have been built in Kuwait, Saudi Arabia, Bahrain, and Qatar.

This lowland region is relatively well supplied with underground water from springs and wells. Deep in the sedimentary strata enormous accumulations of oil and gas have been found.

The western part of the lowland belongs to Kuwait and Saudi Arabia, which share undivided half interests in a Neutral Zone. Saudi Arabia has a similar arrangement with Iraq respecting another Neutral Zone in the interior. Bahrain consists of one large island and a number of small ones. The boundary between Qatar and Saudi Arabia is not fixed. The easternmost part of the lowland, known as the Trucial Coast, is occupied by six of the seven Trucial States. In the hinterland is the oasis of Al Buraymi, which is claimed both by Saudi Arabia on the one hand and by Abu Dhabi and Muscat on the other. After a long-drawn-out dispute (*see* SAUDI ARABIA: *History*) British-officered forces from the latter states occupied the oasis in 1955. (*See* also MUSCAT AND OMAN; BAHRAIN.)

Yemen.—Arabia's highest mountains occur in Yemen: Hadur Shu'ayb, west of the capital, San'a', reaches 12,336 ft. (3,760 m.). The Tihamah in Yemen, broader and more fertile than the Tihamah farther north, supports flourishing towns such as Zabid set back from the coast. Ta'izz in the mountains is served by the port of Mocha (Al Mukha), which won fame in the Middle Ages for the export of coffee. San'a' is served by the old port of Al Hudaydah and its extension, the new port of Ra's al Katib. Off As

Salif, a salt-mining centre on the coast, lies the British-controlled Kamaran Island. Receiving the monsoon rains, the mountains and high plateaus of Yemen form the most fruitful and populous region in Arabia. The easy slope from the highlands to the southwestern corner of the Rub' al Khali was the principal home of the pre-Islamic civilization of south Arabia (*see* SABAEANS), and the ruins of Ma'rib dam, the greatest monument of that age, still stand there. The seaward descent from the mountains of Al Kawr at the southern end of Yemen is precipitous. (*See* also YEMEN.)

Aden and Hadhramaut (*Hadramawt*).—The harbour of Aden, a British crown colony, is formed by two volcanic peninsulas of the lowland below the southern mountain face of Yemen. The southern coast from Bab el Mandeb (Bab al Mandab), the entrance to the Red Sea, to Ra's Darbat 'Ali, a distance of about 800 mi. (1,290 km.), and the hinterland constitute the Protectorate of South Arabia with the colony of Aden. The coast plain, about 30 mi. wide behind Aden, is narrower nearly everywhere else. Along this coast the stream of Wadi Hijir (Hajar), the only truly perennial river in Arabia, flows about 60 mi. to the sea.

Eastward the mountains of Al Kawr merge with the highlands of Hadhramaut known as the Jol (Al Jawl). Hadhramaut strictly speaking is a great interior valley cleaving through the Jol, with its lower course reaching the sea under the name Al Masilah, but the whole of the eastern area of the Protectorate of South Arabia is often loosely referred to as Hadhramaut. The valley contains many old towns such as Say'un and Tarim, the port for which is Al Mukalla. The island of Socotra is attached to the sultanate of Qishn on the coast of the protectorate. In the interior the sand desert of Ramlat as Sab'atayn lies on the slope descending from Al Kawr to the Rub' al Khali, which is gentle both here and going down from the Jol. (*See* also ADEN; HADHRAMAUT; SOCOTRA; SOUTH ARABIA.)

Zufar (*Dhofar*).—The mountains of the tribe of the Qara in Zufar, the southern province of the sultanate of Muscat and Oman, are about 3,000 ft. (900 m.) high, with one peak higher than 5,000 ft. (1,500 m.). The monsoon keeps the seaward side of the mountains fertile, as well as the coast plain, where the provincial capital, Salalah, lies. A gradual slope leads down from the water divide to the Rub' al Khali; many valleys from the slope converge on the area of Ramlat al Mughshin at the desert's edge.

Muscat and Oman.—The name Oman, formerly applied to the whole eastern protuberance of Arabia, is in modern times restricted to the interior on the landward side of the main Al Hajar mountain range, the remainder of the territory being named after the port of Muscat, the capital of the sultanate of Muscat and Oman. The sultan's authority over Oman was disputed in 1955 and 1957 by the pro-Saudi imam of Oman, Ghalib ibn 'Ali, but, aided by British forces, the sultan defeated the imam and drove him into exile.

The mountains of Al Hajar, about 10,000 ft. high in places, differ from the other Arabian coast ranges in being steep on both sides. An imposing fastness near the centre of Al Hajar, called Al Jabal al Akhdar (the Green Mountain), reaches 10,194 ft. (3,107 m.). The coast plain of Al Batinah belongs to the sultanate of Muscat and Oman. North of it is the sheikhdom of Fujairah, the only Trucial State lying wholly on the Gulf of Oman coast. Among the numerous towns of interior Oman is Nazwa (Nizwa), the former capital of the imam. Plains fall away almost imperceptibly from these towns to the Rub' al Khali basin. No mountains bar Oman's outlet to the Arabian Sea in the south, toward Al Masirah Island; the plateau along the coast has an average elevation of about 500 ft. (150 m.). (*See* MUSCAT AND OMAN.)

3. Climate.—Although the Tropic of Cancer bisects Arabia, passing south of Medina, Riyadh, and Muscat, most of the southern half of the peninsula is too high or isolated to be characteristically tropical, the main exception being the lowland coast.

Meteorological records are not full enough to give a detailed picture of the Arabian climate, but the outlines are clear. The summer heat is intense everywhere, reaching 54° C (130° F) in places. Much of the interior is dry, but along the coasts and in some of the southern highlands and deserts the humidity is extreme in the summer. Fogs and dews are frequent in the humid areas, dew often serving as a substitute for rain. In the dry zones the sun blazes fiercely throughout the summer. Spring and autumn are pleasant seasons, and biting cold and snow are rare in winter, except at high elevations and in the far north.

Rainfall is scanty in all parts beyond the reach of the Indian Ocean monsoon, averaging only 3–4 in. (77–102 mm.) a year. The desert rains are torrential on occasion, causing flash floods in the wadis; sometimes these rains turn into hailstorms. It is not unusual for a drought to last several years. The monsoon increases the precipitation fourfold or more in the southwest and south. Lying within the trade wind belt, northern Arabia receives westerlies from the Mediterranean which blow toward the Persian Gulf and then south and southwest through the Rub' al Khali toward Yemen. The monsoon strikes Arabia from the opposite direction. In midwinter and again in early summer the Persian Gulf experiences seasonal winds laden with dust and sand similar to the Egyptian khamsin; in Arabia these are called *shamal* ("north"), though the prevailing direction is actually from the north-northwest. In contrast to the *shamal* is the less frequent *kaus* from the southeast. The wind regimes of Najd and the Rub' al Khali are complex, particularly during spring. The winds may come from any point of the compass and vary in intensity from zephyr to gale.

4. Vegetation.—The date palm grows almost everywhere, except at very high elevations and in Zufar, on the coast of which it is replaced by the coconut palm. The date is a staple in the diet of both townsmen and Bedouins, and uses are found for the trunk, branches, and fibre of the palm. Among places noted for the quality of their production are Medina, Bishah, and Al Hasa (Al Ahsa'). Alfalfa (lucerne), widely used as fodder, often fills the space between palms. The principal grains are wheat, barley, and millet. Evanescent patches of grain planted by nomads in moist wadi beds are often encountered in the desert. Rice has to some extent supplanted wheat as a food, but little is raised locally. Cotton does well in a few places, such as Abyan near Aden. In general the people of Arabia have a greater fondness for fruits than for vegetables. Melons, pomegranates, and the jujube are particularly favoured, and Al Buraymi is noted for its mangoes. Figs, grapes, bananas, prickly pears, and other fruits are also grown, and the citron and Java almond flourish in the oases. The indifference of the Arabs toward vegetables is indicated by the fact that many of those produced in small quantities have non-Arabic names.

Although Arabia is no longer as renowned as formerly for its coffee, fair amounts are still cultivated on the terraced mountainsides of Yemen and 'Asir. In places coffee has given way to the more profitable *qat* (*kat; Catha edulis*), a narcotic. Tobacco is a product of the Hadhramaut coast.

The home of incense in antiquity, Arabia still numbers various aromatics among its herbs, though the trade in frankincense and myrrh has long been languishing. Mimosas and acacias are widespread, but little advantage is taken commercially of their gums. Indigo and other native dyes are extensively used in the south, both for cloth and for ornamenting the human body. Cactus, cactiform *Euphorbia*, and the aloe grow profusely in some areas.

Arabia is not the most hospitable of lands for flowers, but the roses of At Ta'if are well known, the oleander thrives in a desert environment, and other flowers sometimes brighten the general bleakness of the landscape.

The peninsula is singularly devoid of trees. Clumps of junipers in the southwestern highlands make the closest approach to true forests. The tamarisk, which grows well without much water, is often planted in rows to retard the encroachment of drift sand. The *rak* tree supplies the local version of the toothbrush. Trees are so rare that the standard Arabic word for tree, *shajar*, is ordinarily used by the Bedouin for bushes in the desert which furnish grazing for his animals and firewood for his tent. The leaves of varieties called *hamd* have enough salinity to satisfy the camel's need for salt. The tough perennials are as essential to life as the tender annuals nourished by the rains of winter and spring. The rains also assist in growing the truffle (*q.v.*), which the Bedouins dig out of the ground.

5. Animal Life.—The camel is the chief support of nomadic life in Arabia. Without the camel the Bedouin could never move far from water fit for human beings; with the camel he can survive for months on its milk and penetrate deep into the deserts. The camel also furnishes food, clothing, fuel (dung), transportation, and power for drawing water or for plowing. For the Bedouin the camel represents the best form of capital and the most valuable article of commerce. The noblest breeds of camel come from Oman, but some of the more plebeian breeds show greater stamina. Sheep and goats, known collectively in Arabic as *ghanam*, are numerous, but Arabia has no great herding tribes to compare with those farther north. Mutton and lamb are the favourite meats, and goat's milk makes the best cheese. Ghee (clarified butter) is used universally in cooking. The Arabian horse, noted for its beauty and endurance, is a disappearing strain in Arabia, where only a few thousand remain, though the breed is now fostered in other countries. A large white donkey is raised in eastern Arabia. Cows are usually small and humped, though the humpless variety is found on Socotra. Chickens tend to be of inferior quality. Many Bedouins own salukis, a speedy hunting dog; trained falcons are also used in the chase. Gazelles used to range the plains in large numbers, but formerly unrestricted hunting decimated them. Very few oryx are left in the Rub' al Khali, their last stronghold, and the ibex has also become rare. Other large wild animals are the hyena, wolf, and jackal. Despite the multiplicity of names for the lion in Arabic, the beast itself has long been extinct in Arabia. Baboons abound in the southern mountains. Among the smaller animals are the fox, ratel, rabbit, hedgehog, and jerboa.

Deadly desert snakes are the horned viper and a species of cobra differing considerably from the Indian. The striped sea snakes are also poisonous. Large lizards include the desert monitor, and the smaller lizards the sand-swimming skink.

Ostriches have become extinct. Eagles, vultures, and owls are common, and the lesser bustard is often hunted with falcons. Flamingos, pelicans, egrets, and other sea birds frequent the coasts. Smaller birds found in the towns and oases include the pigeon, cuckoo, swallow, and hoopoe, while the sand grouse, lark, and courser inhabit the desert.

The seas around Arabia contain mackerel, groupers, tuna, porgies, and other food fish, as well as shrimps. Sharks and sardines are plentiful off the southern coast and whales occasionally enter the Persian Gulf.

Swarms of locusts periodically descend as a plague, devouring every green plant in their path. Other common insects are the fly, which appears out of nowhere even in the depths of the desert, the mosquito, tick, beetle, scorpion, and ant. In some places bees are kept for their honey.

II. NATURAL RESOURCES

The mineral resource of greatest value so far discovered in Arabia is oil. Kuwait and Saudi Arabia are leading countries in world production, and the Arabian Peninsula holds perhaps a third of the world's reserves.

The Arabian oil fields lie in the same great sedimentary basin as the fields of Iran and Iraq. Although oil was discovered in Iran in 1908, the first field on the Arabian side of the basin, in Bahrain, was not found until 1932. The appearance of oil in Bahrain inspired an intensive search in eastern Arabia which in time reached far into the interior. Oil was discovered in Saudi Arabia and Kuwait in 1938, in Qatar in 1939, on the mainland of the Saudi Arabian/Kuwait Neutral Zone in 1953, on the mainland of Abu Dhabi in 1959, and in Oman in 1964. In 1951 oil was discovered in the Persian Gulf off Saudi Arabia, in 1958 in the Abu Dhabi offshore, and in 1960 in the Neutral Zone offshore. These discoveries, coupled with favourable geological prospects, provide a strong incentive for continued large-scale exploration. Oman, Zufar, Hadhramaut, Yemen, Najd, and the Red Sea coast and islands are regions where oil may exist in commercial quantities.

Saudi Arabia's proved reserves in the mid-1960s were estimated at about 70,000,000,000 bbl. and the estimate for Kuwait was well over this figure. In association with the oil are enormous amounts of natural gas; Saudi Arabia's reserves were estimated at more

BY COURTESY OF ADEN PUBLIC RELATIONS AND INFORMATION DEPT

THE REFINERY AT LITTLE ADEN PROCESSES 5,000,000 TONS OF CRUDE OIL A YEAR: ADEN HAS NO OIL FIELDS OF ITS OWN

than 25,000,000,000,000 cu.ft. Making use of this gas commercially requires extremely large investments. Some gas is liquefied for local consumption or for export, some is reinjected into the oilbearing strata for storage and to help maintain pressure for oil production, and the rest, because of the poisonous elements it contains, has to be burned in flares.

Europe is the principal customer for Arabian oil, taking about half the production. The Far East comes next, followed by the Western Hemisphere, where both the United States and Canada import considerable quantities, and the Near East. (*See* also PETROLEUM: *After World War II*.)

Whether the biblical Ophir (*q.v.*) lay in Arabia or not is open to conjecture, but many ancient mining sites bear witness to the once flourishing production of gold. Between 1934 and 1954 gold and silver worth more than \$30,000,000 (£10,000,000) were taken out of the old mine of Mahd adh Dhahab in Hejaz, but no other site for gold that would be profitable under present conditions has been found. As igneous and metamorphic areas often contain rich deposits of minerals and precious stones, thorough scientific surveys of both the Arabian shield and Yemen are needed, and the governments of Saudi Arabia and Yemen endeavour to promote them. Deposits of iron have been found in northern Hejaz and Najd, but it has not been determined whether exploitation is economically feasible. Other resources, some of which are being used, are copper, barite, gypsum, salt, lime for cement, clay for bricks and pottery, shale, quartz sand for glass, marble, and building stone.

For many centuries the oyster beds of the Persian Gulf produced some of the world's finest pearls, and pearling was once a thriving and profitable occupation, with Bahrain as the chief centre and participation by the Trucial States, Qatar, and Saudi Arabia. Since about 1931 the trade has suffered a sharp decline as a result of the world economic depression, the competition of Japanese cultured pearls, and the siphoning off of labour into other less onerous and more lucrative fields. As the use of mechanical devices for stripping the pearl beds is forbidden, this resource remains abundant, and an increase in the demand for the delicately shaped and tinted Persian Gulf pearl might enable the pearling business to return to its former level of prosperity.

Even in the southwest, where rainfall is heaviest, the water supply is not constant enough for the generation of power. The water scarcity and the frequent poverty of the soil have hampered the development of an export trade in agricultural produce. Some progress has been made in improving the irrigation system and expanding the cultivated area. (G. S. RE.)

III. THE PEOPLE

According to ancient tradition, the Arabs are originally descended from two stocks. Of these the first were believed to have

originated in the uplands of the southwest corner of the Arabian Peninsula, while the second or northern group were those located in northern central Arabia and often alleged to be the descendants of Ishmael (*q.v.*), the son of Abraham. To this day almost every Arab tribe claims to be descended from one or other of these two stocks. It seems probable that these legends, so firmly rooted in tradition, did at one time represent some actual racial variants but, if so, their distinguishing features have long been lost.

A more practical division of the peoples of the Arabian Peninsula, who probably number 10,000,000–12,000,000, is that between the nomads and the settled communities. So scanty and precarious is the Arabian rainfall that the natural grazing available for livestock is everywhere sparse. A flock of sheep or a herd of camels will soon consume all the grazing in any given area, whereupon the owners are obliged to move camp in search of fresh grazing elsewhere. As a result, all the large-scale rearing of camels and sheep must perforce be done by nomadic tribal communities.

As opposed to the nomads, the settled communities live in towns and villages, either on the springs or wells of central Arabia or along the sea coasts. In central Arabia the settled population live either by agriculture, chiefly gardens of date palms, or by acting as middlemen, buying camels, sheep, wool, or animal oil from the tribes and exporting it to neighbouring countries such as Egypt, Syria, or Iraq. These commercial voyages abroad enabled the townspeople of central Arabia to acquire a certain familiarity with other civilizations and thus exercised a refining influence on Arabian society. As contrasted with these settled communities, the Arab nomads, or Bedouins, devoted the greater part of their time to raiding, hunting, and war, were capable of enduring severe physical hardships and, until after World War I, terrorized central Arabia and the surrounding territories. The settled inhabitants themselves, in most cases, were descended from the nomadic tribes and were considerably influenced by their warlike traditions. Thus they formed, as it were, a bridge connecting the tribal warrior class with the civilizations of the outer world.

The mountainous regions of Yemen and, to a lesser extent, of Hadhramaut received rain from the monsoon and a higher level of agriculture was possible. The earliest wealthy Arab kingdoms were established in these southwestern mountain regions at least 1,000 years before Christ, spices being in those days a principal export. Although the fertility of their country should, in theory at least, have resulted in a high standard of civilization in Yemen, the inaccessibility of their mountains and the fanaticism of their religion kept Yemeni society in a medieval stage of development until mid-20th century.

Muscat and Oman has for a long time been considerably influenced by the India-Pakistan subcontinent. There is a sprinkling of Indian inhabitants and more particularly of Balochi (*q.v.*). Many of the sons of the chiefs went to India for their education. The Arabs of the Persian Gulf and the seaboard of the Indian Ocean, unlike the northern Arabs, have always been great traders and seafarers. Hadhramaut has long had an intimate connection with Malaya, a fact which emphasizes the skill in navigation developed by these southern Arabs. Many of the inhabitants of the Persian Gulf coast provinces of Arabia lived by pearl fishing till the industry declined (*see* above, *Natural Resources*).

The province of Hejaz is set apart by the fact that it contains the Muslim sacred cities of Mecca and Medina (*qq.v.*), venerated by the whole Islamic world. Some of the pilgrims who flock there settle in the holy cities in order to terminate their lives on holy ground. Thus, although the inhabitants of the open country of Hejaz consist of largely tribal oasis dwellers and nomads, similar to those of central Arabia, the holy cities and the Meccan seaport, Jidda, contain extremely cosmopolitan populations.

There are few racial minorities in Arabia and indeed the population of central Arabia must be one of the most homogeneous communities in the world. The sole important exception is that of the African Negroes. In the past the Arabs were considerable owners of slaves, and slavery was not abolished in Saudi Arabia until 1962. However, partly for economic reasons and partly because slavery is now illegal throughout Arabia, the Negro population is free, living and working with and beside the Arabs. In certain especially hot areas, such as the oasis of Khaybar in Hejaz, Negroes appear to congregate particularly and to have intermixed with the local people. Considering the length of time during which Africans have been living in Arabia it is surprising that they have not intermarried more with the Arabs.

Such was the general picture of the peoples of Arabia until World War II. The discovery of vast oil fields in Arabia near the shores of the Persian Gulf, however, rapidly began to transform the whole scene. The exploitation of the oil wells was not seriously undertaken until 1943 and 1944. Thenceforward central Arabia, which in the past had been almost closed to Europeans, was suddenly thrown open to great numbers of United States oilmen and their families. In addition to senior officials and technicians, the oil companies needed a great number of minor employees, such as clerks, and foremen, drivers, fitters, and lower-grade technical staff. So primitive were educational standards in the country that the companies were obliged to import nearly all this personnel from Lebanon, Syria, Jordan, Iraq, or Egypt, countries with more modern social organization than existed in central Arabia. The impact of this invasion of Arabic-speaking semiskilled workers could not but be considerable.

The sight of "foreign" Arabs occupying so many lucrative posts in their country naturally impelled the Saudi Arabians to demand technical education for themselves, with the result that, for the first time, students were allowed to go abroad to study. Thus Arabia was suddenly propelled from a primitive patriarchal society straight into the modern oil age. At the same time, Saudi Arabia and some of the smaller Persian Gulf sheikhdoms, previously among the poorest countries in the world, became immensely rich. No oil had been found in Yemen or Hadhramaut by mid-20th century, with the result that in those countries the old social conditions still prevailed.

See further ARAB; BEDOUIN. For population figures *see* articles on the individual countries. (J. B. GL.)

IV. EXPLORATION

The exploration of Arabia is virtually complete, except for parts of Yemen. The term exploration, however, is perhaps a misnomer. Arabia has never been an unknown country, and it has at all times been inhabited even in its remotest quarters. It was divided by the Romans into Arabia Petraea (rocky Arabia) in the Sinai, Arabia Deserta (desert Arabia) in the northern interior, and Arabia Felix (fertile Arabia), usually restricted to Yemen but used by Ptolemy to describe most of the peninsula (*see* also ARABIA, ROMAN PROVINCE OF). In the past its inhabitants had little use for the instruments of the map maker or for the presence of infidels or unbelievers. But Muslims from every part of the world have always been welcome, and many of these were learned men who left interesting and informative accounts of their pilgrimages to Mecca and Medina.

Arabia has mainly appealed to two kinds of travelers—those interested in examining the precepts of Islam as manifested at its centres in the holy cities and those wishing to acquire fresh knowledge by exploring difficult and inaccessible terrain. To the ancient world it was known as the source of spices and incense, eagerly sought after by Sumerians, Babylonians, and Egyptians. So far the only accounts of such trading ventures in this area have been from the latter, if "God's Land" and the "Land of Punt" can be accepted as referring to southwest Arabia as well as to Ethiopia and Somaliland. There is no doubt that the Sumerians journeyed along the east coast to Muscat and Oman in search of gold and other precious materials. In the 8th century B.C. the Assyrians conquered the north Arabian tribes, who were a constant threat to the security of the overland trade routes from Yemen and Hadhramaut. The first connected accounts of the Arabian coastal region come from the classical writers Pliny, Theophrastus, Strabo, and the unknown author of *The Periplus of the Erythraean Sea*, written about A.D. 60. Further information about land routes was brought back by those who took part in Aelius Gallus' ill-fated expedition sent by Augustus to explore the region of the Arabian Gulf and to reduce the tribes to submission.

After the rise of Islam in the 7th century, Arabia became a closed area to those not professing the faith, but in the Middle Ages a large number of Muslim travelers visited the holy places and left records of their journeys. Among these may be recorded Ibn Hauqal and al-Maqdisi (Muqaddasi), both in the 10th century, Idrisi and Ibn Jubayr (12th century), Abdul Feda and Yaqut (13th century), and Ibn Batutah (14th century).

1. Early European Travelers.—European interest in Arabia may be divided into three periods: first, travels from the 15th to the 18th centuries, some of them involuntary, as in the case of Europeans captured and sold as slaves; second, the period of 19th-century exploration; and third, 20th-century travels, scientific missions, and oil surveys. The first recorded European to visit Arabia is Pedro de Covilhão (*q.v.*), who is known to have touched at Aden in 1493 on his way to Ethiopia. One of the earliest Europeans to stay any length of time in the country was an Italian, Lodovico di Varthema (*q.v.*), who traveled extensively in Arabia, Syria, Palestine, India, and Ethiopia. He enrolled himself in the corps of Mamelukes in Damascus and so accompanied the *hajj* (pilgrimage) to Mecca. His description of the city and the religious ceremonies carried out were to a large extent supported by such later travelers as J. L. Burckhardt and Richard Burton. Varthema also visited Aden and Lahej, which he describes in accurate detail. His book on his travels appeared in Rome in 1510.

The next to visit Arabia were the Portuguese under Affonso de Albuquerque (*q.v.*), who in 1513 made an abortive attack on Aden with the object of closing the Red Sea to Muslim commerce, and who later sailed along Yemen and acquired a knowledge of the coastal area. According to Albuquerque's commentaries, Gregorio da Quadras, a Portuguese captain wrecked off the Yemen coast, crossed Arabia after great difficulties and arrived at Hormuz (Ormuz), a Persian Gulf island. If this account is correct, Da Quadras was the first European to cross the Arabian Peninsula.

2. 17th and 18th Centuries.—In the early years of the 17th century the English East India Company was trying to force a way into the Indian trade. By this time Aden and Yemen were in Turkish hands, and in 1609, when Alexander Sharpeigh visited Aden in the "Ascension," he was not allowed to trade without Turkish permission. John Jourdain, the factor on the ship, traveled to San'a', the capital of Yemen, to arrange matters, and returned overland to Mocha. He thus became the first Englishman to travel inland in Yemen. An involuntary English visitor to Mecca and Medina was Joseph Pitts, captured at sea in 1678 as a boy of about 15 or 16; after forcible conversion to Islam he accompanied his master to Mecca, later publishing, on his return to England, a description of the town and an account of his journey. By the end of the 17th century the coasts of Arabia were fairly well known; the Persian Gulf had been examined by ships of the East India Company as well as by Dutch and Portuguese vessels. The Portuguese fort at Hormuz controlled shipping in the Persian Gulf until its capture by the Anglo-Dutch fleet in 1622. J. B. d'Anville's chart of Arabia of 1755 still had some serious mistakes: the Persian Gulf and the Red Sea were too small, and the position of deserts such as the Great Nafud was not shown.

The first scientific expedition to visit Arabia was a Danish one, sent out between 1761 and 1764 for the purpose of biblical and geographical research. The main object was to visit Yemen, once more independent; this region had already been partly explored by Jourdain, Sir Henry Middleton, and the Frenchmen Barbier and De la Grelaudière. The Danish expedition consisted of a doctor, botanist, zoologist, orientalist, and surveyor, but only Carsten Niebuhr (*q.v.*) survived to return to Denmark. Landing at Al Luhayyah on the coast of Yemen, they explored the Tihamah, visiting Ta'izz, San'a', and the mountains. They investigated the coast fairly thoroughly but met with less success and a good deal of suspicion in the mountain regions. At Mocha they got into difficulties and lost some of their equipment. Niebuhr gives a description of San'a', and, though he was unable to draw a ground plan, his account served as useful information for later travelers. His report on Yemen and his information about the recently formed Wahhabi movement provide the first scientific account of Arabian affairs.

3. 19th Century.—*Hejaz and Najd.*—In the 19th century the number of travelers to Arabia greatly increased. Mecca and Medina were frequently visited and described, and the position of the former was accurately ascertained. The first to visit the holy cities in this period was a Spaniard, Domingo Badía y Leblich, who went under the name of 'Ali Bey al-Abbasi and claimed to be a descendant of the Abbasids. He traveled in state with a train of servants and with scientific instruments. Landing at Jidda in 1807, he went to Mecca and fixed the position of that city at latitude 21° 28′ 9″ N, longitude 40° 15′ 0″ E of the meridian of Greenwich. These figures conform closely to the position now recognized. Unfortunately his chronometer was stolen near Mecca. He was turned back from Medina by the Wahhabis but was able to describe the lava formations of western Arabia and the routes to and from Medina and Mecca to the coast. He was able to fix by astronomical observations at least 18 places on the Red Sea. In 1818 he died on his way to Mecca for a second time, traveling overland from Damascus.

'Ali Bey was followed by Ulrich Jaspar Seetzen, a botanist with a European reputation serving at the Russian court. An accomplished Arabist, he nevertheless seems to have aroused a certain amount of suspicion, and although he performed the pilgrimage unharmed he was murdered near Ta'izz in Yemen after extensive travels in that country and in Hejaz. The next Arabian traveler was Johann Ludwig Burckhardt (*q.v.*), who under the name of Ibrahim ibn Abdullah posed as a learned doctor. After perfecting himself in Arabic in Aleppo, he visited all of Syria and later discovered Petra (*q.v.*). In 1814 he disembarked at Jidda and went to Mecca and later Medina. His main interest was in the trade, social life, and religion of the Arabs. His topographical information is somewhat meagre, as he traveled at night and had no instruments save a ship's compass, but his description of the *hajj* and of Mecca has seldom been surpassed. He remained in the country for nine months but was ill for the greater part of the time and died within a few years of his return to Cairo.

Richard Francis Burton (*q.v.*), a British officer on leave from the Indian army, landed in Yanbu' (Yenbo) in 1854 and proceeded to Medina. He followed the inner route, or Darb al Sharqi, to Mecca, a track previously unknown to Europeans. From Mecca he had intended to travel overland to Muscat, thus crossing Arabia; but he found that the journey was not practicable and was obliged to abandon the idea. The last noted European to visit and describe Mecca in the 19th century was the Dutch orientalist Christiaan Snouck Hurgronje (*q.v.*), who spent five months in Jidda and five months in Mecca. He published a detailed account of life in Mecca, of particular value since he stayed there at a period when the *hajj* was not taking place.

Central Arabia was visited by a number of travelers in the 19th century, after the overthrow of the Wahhabi power by Ibrahim Pasha in 1818. The first was Capt. G. F. Sadlier, who was sent in 1819 by the British administration in India to sound Ibrahim Pasha with regard to the suppression of piracy in the Persian Gulf. Starting in June of that year, he reached Al Hufuf (Hofuf) and followed the retiring Ibrahim to Medina, later leaving the country at Yanbu'. Sadlier was the first Englishman to cross Arabia, and as a result of his conscientious observations the distances between many points in central Arabia were established. He was followed in central Arabia by a Finnish Swede, George Augustus Wallin, who, proficient in the language, was disguised as an Arab. In 1845 he reached the Jabal Shammar via the Wadi 'Arabah and the Wadi Sirhan and went on to Al Jawf and Ha'il. Wallin supplied some useful information about the tribes and their localities, although he was equipped only with a compass. He crossed the Great Nafud and later made his way to Mecca and Medina. In 1848 he returned to Ha'il, crossing from the Red Sea coast at Al Muwaylih through virtually unknown country. He died in 1854 before his work really became known.

The next visitor to Ha'il was an Englishman, William Gifford Palgrave, whose intimate knowledge of Arabic led him to write a remarkable account of his journey but whose florid style has led

to doubts as to its authenticity. H. St. J. Philby has disputed his account, but Palgrave had the support of D. G. Hogarth and later R. E. Cheesman. In 1865 Col. Lewis Pelly visited Riyadh to see Faisal ibn Sa'ud, with whom he established friendly relations; but he could do nothing with regard to the suppression of the slave trade and piracy in the Persian Gulf, the real object of his journey. As a result of his sojourn the positions of both Riyadh and Al Hufuf were fixed. Pelly was one of the first to describe the Selaib, a non-Bedouin people about whose origin little is known. Al Jawf was visited in 1851 and 1864 by Carlo Guarmani, an Italian Levantine, who went there to buy Arab horses. His observations were extremely useful to later cartographers, and his maps were published by the Franciscans at Jerusalem. Charles Huber, an Alsatian resident in Syria, also crossed the desert to Al Jawf and Ha'il some years later, in 1878. He returned accompanied by a German archaeologist, Julius Euting, but they were not on good terms and parted after going to Tayma' and purchasing the famous Tayma' stone now in the Louvre. Euting was later attacked by Bedouins but escaped; Huber was less fortunate and was murdered by his guides near Rabigh in July 1884.

In the same year that Huber was at Al Jawf, Wilfrid Scawen Blunt (*q.v.*) and his wife, Lady Anne Blunt, visited Najd accompanied by a young Palmyran sheikh who was searching for a bride among his kinsfolk. His protection enabled the Blunts to travel openly as Europeans and to collect Arabian horses for the establishment of the Crabbet Park stud. They returned to Baghdad via the Persian pilgrim route. Charles Doughty (*q.v.*) traveled down from Damascus to Mada'in Salih to copy the inscriptions. After doing so he went to Tayma', Jabal Shammar, and Ha'il, traveling openly as a Christian. He emerged at Jidda in 1878, having spent 21 months in Arabia. On his return to England he produced a book, *Travels in Arabia Deserta*, regarded by many as the classic of Arabian travel.

The last of the 19th-century travelers to central Arabia was Baron E. Nolde, who crossed the Nafud and visited Ha'il and Ash Shaqra' in 1893, returning via the Persian pilgrim route. Though he contributed little of topographical value, he compiled considerable information on the climate, animal life, and vegetation. Thus it was by the end of the century that the northern part of Arabia had been extensively explored. It is perhaps not chance that the really famous names in Arabian exploration are connected with Hejaz and Najd. 'Ali Bey, Burckhardt, Burton, and Doughty produced books that are classics of exploration and that only those who eventually crossed the Rub' al Khali could emulate.

The Southwest and Southeast.—The southwest and the southeast regions of Arabia were not so extensively explored at an early date. In 1835 the British East India Company dispatched Lieut. James Wellsted to ascertain how far the power of the sultan of Muscat extended inland. He traveled extensively in the interior of Muscat but could not penetrate beyond Obri because of the Wahhabis. Wellsted also pioneered in Hadhramaut, visiting the ruins of Naqb al Hajar and collecting the first Himyaritic inscriptions. He was followed in Oman many years later by Col. S. B. Miles, who crossed the mountains from Suhar to Az Zahirah, visiting Al Buraymi oasis and collecting material for his work on the tribes of the Persian Gulf. In 1843 Adolf von Wrede, a Bavarian from Egypt, entered Hadhramaut disguised as a Muslim pilgrim visiting the tomb of the prophet Hud. He was recognized and never reached his destination but was returned to Al Mukalla with the loss of his notes and baggage. Wrede's information, communicated to the Royal Geographical Society by Captain Haines of H.M.S. "Palinurus," was the earliest account received of the fertile Hadhramaut valleys. He failed to climb the main valley, but this was made up for by the explorations of Leo Hirsch and Theodore Bent, who made a useful survey of this area.

After Niebuhr, there were no travelers of note to the southwest for a long time. Then came Louis Arnaud, who penetrated Yemen from Jidda and went to Ma'rib, where he studied the inscriptions and the dam. Twenty years later he was followed by Joseph Halévy, a French Jew from Edirne (Adrianople), sent out by the Académie des Inscriptions et Belles-Lettres. He visited the ruins of Ma'in and Khirbet al Bayda' (Roman Nesca), where the Romans under Aelius Gallus defeated the Sabaeans in 24 B.C. Halévy copied more than 600 inscriptions and made various contacts with the Jewish colonies in Yemen at Najran and elsewhere. Éduard Glaser, an Austrian archaeologist, also visited this region in 1889 and collected inscriptions from Ma'rib and other parts of the country. His copies numbered more than 1,000, and these two collections formed the basis of the *corpus* of south Arabian inscriptions. Travel in the interior of Yemen continued to be difficult, but accounts of San'a' and other cities in the interior began to appear toward the end of the century from such authors as R. Manzoni and W. B. Harris.

4. 20th Century.—The north Arabian deserts became well known as the result of the work in the first two decades of explorers such as Gertrude Bell (*q.v.*), Alois Musil, Lieut. Col. G. E. Leachman, W. H. I. Shakespear, Douglas Carruthers, H. St. John Philby, and Maj. A. L. Holt. Their interests were varied, including botany, archaeology, surveying, hunting, and politics, but they all added their quota to the increasing knowledge of this area. Shakespear was killed in 1915 in a battle between Ibn Saud and Ibn Rashid, but it was largely because of his careful cartography that maps of the central and eastern portion of Arabia could be compiled. His work on the east was continued by H. R. P. Dickson, working from Kuwait, who also collated and published some useful information about the tribal customs in this region. In Al Hasa Maj. R. E. Cheesman mapped the region and made an important botanical survey.

The Rub' al Khali.—The major interest of 20th-century exploration in Arabia was focused, however, on the crossing of the Rub' al Khali. This was accomplished by three men, independently of each other: Bertram Thomas in 1930–31, Philby in 1932–33, and W. P. Thesiger in 1948–50. Thomas crossed from Zufar in the south to Qatar on the Persian Gulf. His expedition was not just a dash across the sands at their narrowest point but was carefully prepared. He collected valuable geological, anthropological, and botanical information in the course of his journey. Thomas, an accomplished Arabist, was vizier to the sultan of Muscat. He traveled in Arab clothing but was not disguised. He discovered that only part of this great desert was uninhabitable, as the southern sands at Dakkah are occupied by the Rashidi tribes. He was fortunate in that his crossing was helped by local rain, which supplied fodder for his camels. As a result of his journey he was able to write one of the best works on Arabian exploration, *Arabia Felix*.

Philby, who had been living in Saudi Arabia for some time, had been planning the same journey, but from east to west. He crossed the northern Empty Quarter from Al Hufuf but was unable to penetrate to Zufar for lack of a *rabia* (surety). He also collected information of interest to geologists and natural historians. First a political officer with the Mesopotamian Expeditionary Force, Philby later resigned from government service and settled in Mecca, having become a Muslim. With the aid of Ibn Saud he made a series of journeys throughout central and western Arabia, and as a result of his work it became clear that there was no chain of oases linking Najd with either 'Asir or Yemen, or between Najd, Oman, and Hadhramaut. One of the most interesting facts he recorded was the presence of a permanent lake at Umm al Jibal, south of Layla, and he also noted the existence of water tanks and supplies at Aflaj and Al Kharj.

The last traveler to cross the Empty Quarter was Thesiger, who had already made long journeys in Arabia on behalf of the Locust Control. Starting from Zufar, he crossed to the eastern section of Oman and later retraced his steps to the south. All these three travelers suffered from the unsettled conditions rife throughout this territory, where raiding was a constant threat. With Thesiger's journey ended the last great phase in Arabian exploration.

The South and Southwest.—The rich valleys of the south and southwest also received a number of explorers in the 20th century. Yemen still remained for the most part inaccessible, although A. J. Wavell, Col. H. F. Jacob, and G. Wyman Bury all visited the country before 1914. Bury lived there for many years and did much exploratory work on behalf of the Royal Geographical Society. In 1937 a visit was paid to the Yemen mountains by Hugh Scott

BY COURTESY OF (RIGHT) STANDARD OIL CO. (N.J.), PHOTOGRAPH, (LEFT) CAMERA PRESS-PIX FROM PUBLIX

AGRICULTURE IN ARABIA. (LEFT) EXPERIMENTAL FARMS IN KUWAIT GROW VEGETABLES AND CITRUS FRUITS. (RIGHT) BREAKING GROUND WITH PRIMITIVE TOOLS IN SAUDI ARABIA

to make a collection on behalf of the British Natural History Museum. During 1950–52 the American Foundation for the Study of Man conducted archaeological work in Yemen at Ma'rib and elsewhere and also in Hadhramaut.

Hadhramaut was explored, mapped, and described by a number of modern travelers, including O. H. Little, Freya Stark, Harold Ingrams, H. von Wissmann, and D. van der Meulen. The last of these was a Dutch official who was attracted to Hadhramaut through his contacts with emigrants from Arabia in the Dutch East Indies. He undertook a number of journeys in Hadhramaut, of which he left interesting accounts, and eventually was appointed Netherlands minister in Jidda.

Mecca and Medina.—The 20th century has seen further visits to Mecca on the part of Europeans, such as that paid by A. J. Wavell before World War I. He left an excellent account of Medina and Mecca and later visited San'a' in 1911. In 1925 Eldon Rutter, who had learned Arabic in the Malay States, went to Hejaz. He approached from the south, from Al Gaham on the coast to 'Asir, and spent a year traveling in and about the country at the time the Wahhabis were reestablishing their power. In addition to Rutter's account of his experiences, there have appeared a number of books by Muslims of European origin who made the pilgrimage in the middle of the century.

Later Developments.—With the consolidation of Ibn Saud's power in Saudi Arabia after World War I, conditions in this region became increasingly stable; and after World War II there was an influx of foreign technicians, geologists, agricultural experts, entomologists, and economists. The Arabian American Oil Company (Aramco) has explored and surveyed extensively in eastern and southeastern Arabia, particularly in Al Hasa province. An American mining engineer, K. S. Twitchell, sent to Saudi Arabia in 1942 on behalf of the U.S. government agricultural mission, conducted investigations into the natural resources of the area, not only in Hejaz and Najd but in Al Hasa, 'Asir, and Yemen. Such ventures marked a new development in the history of Arabian exploration.

With the advent of the airplane and motor car to Arabia the old days of nonremunerative exploration were over; but the discovery of Arabia had been the work of men who ventured alone with no resources behind them, pitting wits and endurance against an often merciless environment.

V. ARCHAEOLOGY

No adequate archaeological survey of the Arabian Peninsula has been undertaken, and the rather scanty information available depends to a large extent upon the interest and knowledge of travelers, agricultural experts, oil men, and officers of the Locust Control. The difficulties of archaeological work in this region are great, and the problems relating to the pre-Islamic period do not interest the local rulers, who are on the whole reluctant to issue permits. Only in the south and on the eastern coast has some intensive exploration and excavation been undertaken.

It is evident that Arabia was the home of Paleolithic hunters. Flint tools of Acheulean type, including hand axes, have been found at Ad Dawadimi in central Arabia. Other Paleolithic-type tools were discovered in Al Hasa and Hadhramaut. Travelers crossing the Rub' al Khali have reported the presence of flint tools of Neolithic or Bronze Age types.

1. North Arabia.—Archaeologically, Arabia may be divided into the northern region and the southern, the north having settlements only in the oases; while the south and southwest are habitable over a wider area. No archaeological work has been done in the north except in the coastal areas of Al Hasa province near the Persian Gulf. Work in this region was linked to that on Bahrain Island, where burial mounds have been found and investigated at intervals since 1879. These are extremely difficult to date because of the lack of related material. Cairnlike mounds (tumuli), consisting of loosely piled stones over a crude oblong cist burial, also occur on the mainland. Mounds of this nature have been reported from all over Arabia, varying in size from 6 to 20 ft. (2–6 m.) in height and from 10 to 60 ft. (3–18 m.) in diameter, but only a few have been investigated.

At Jawan, where a pre-Islamic and Islamic cemetery of this type was cleared, the earliest graves have been dated to between the 6th and 4th centuries B.C. Investigation of other mounds would probably indicate that they range in date from prehistoric times to the present day, as nomadic burial customs are very similar. Such mounds are usually found in areas where there are wells or subterranean water. They should not be confused with the stone circles which have also been reported from the Red Sea side of Arabia. These were probably refuges for herding animals in times of danger and are well known from farther north in the Arabian desert. Tumuli were not the only mode of burial in Arabia; in the northwest at Mada'in Salih and Al 'Ula, rock-cut tombs of Himyaritic and Nabataean date have been found. These may be as large as 18 ft. square, cut in the soft limestone, and decorated with facades strongly marked by classical influence.

Inscriptions have been found in north Arabia, consisting mainly of graffiti, cut or scratched by nomads. There are three groups of these—Thamudenic, Lihyanic, and Safahitic—and they are usually dated from between the 1st and 2nd centuries B.C. down to about the 4th century A.D.

Ruins of ancient cities have been reported from various parts of the Arabian plateau, but on examination certain of these have turned out to be natural rock, usually of volcanic origin. There is, however, a large ruin at Daht al Oukdud in the Najran Valley, covering an area of about 20 ac. (8 ha.) and containing numerous Himyaritic inscriptions. Rectangular temples are known from Sirwah, Ma'in, Riyan, and Medinat Haram.

2. South Arabia.—The material from south Arabia consists mainly of sculpture, frequently in alabaster. Some of these pieces show classical influence, others Phoenician. Bronzeworking was a south Arabian specialty and a large number of bronze figures must have existed in the temples, although only a few examples are now remaining. The lion riders from Timnah show a marked technical excellence. Coins, minted by the Qataban kings, follow Hellenistic models. An examination of the irrigation works at Bayhan (Beihan) and Wadi 'Amd has shown some of the most remarkable of the south Arabian achievements, consisting of a series of tanks and drainage channels used in former times for the

cultivation of incense trees and spices. Over a large portion of the area *qanats*, or underground water systems, thought to have been derived from Persia, were found. The tradition of fine stone-working begun by the early south Arabian architects can still be seen in the modern towns of Yemen and Hadhramaut.

The most important part in pre-Islamic Arabian history was played by the kingdoms of south Arabia, Ma'in, Saba (Sheba), Qataban, and Himyar (*see* below). Because of the lack of stratified deposits and controlled excavation in these regions, the chronological order of the rulers of these kingdoms has not been finally settled. They owed their prosperity to the incense trade, an important commodity supplied to both Mesopotamia and Egypt and later to Greece and Rome. There is archaeological evidence in Ethiopia to indicate an influx of population from south Arabia before the classical period.

Since Carsten Niebuhr first drew attention to the south Arabian inscriptions in 1772, these have been of the greatest interest alike to the philologist and the archaeologist. But circumstances have made it easier in this area to excavate temples rather than town sites, and as a result the areas dug have not supplied sufficient stratigraphical information. In 1928 C. Rathjens and H. von Wissmann excavated a temple dedicated to a sun-god called Dhat Badan at Hugga in Yemen, and dated it to between 100 B.C. and A.D. 300. In 1937–38 Miss G. Caton Thompson excavated a temple at Al Huraydah in Hadhramaut, dedicated to the moon-god Sin and used between the 6th and 3rd centuries B.C. In 1950–52 the American Foundation for the Study of Man carried out work in Wadi Bayhan in Hadhramaut, at Timnah, the capital of Qataban, and at Ma'rib, the capital of Saba. The Bayhan and Ma'rib excavations were important as serving as a cross check upon one another. At Ma'rib the temple dedicated to the moon-god was only partially cleared, but it appears to have been built in the 8th century B.C. It was a large oval building, 984 ft. (300 m.) in circumference, with an imposing entrance court surrounded by inscribed stones. To the east was a mausoleum contemporary with the temple. In this region, as in other parts of the ancient world, tombs were grouped around important sanctuaries. The end of this site may be dated to the bursting of the Ma'rib dam in the mid-6th century A.D.

The most difficult task in south Arabia has been the deciphering of the inscriptions and the dating of the respective dynasties and establishment of their interrelationship. These kingdoms were almost continually at war with one another, and written evidence for their activities comes, as is so often the case, from classical authors without direct knowledge of the problems concerned or writing later than the events chronicled. There are two schools of thought as to the dating of these dynasties: one, represented by É. Glaser and F. Hommel, advocates a date in the 2nd millennium B.C., while the other, represented by F. V. Winnett, D. H. Muller, W. F. Albright, and A. Jamme, would place Saba at the beginning of the 8th century B.C. and Ma'in in the 5th century. Jamme and Albright suggest that Qataban began at least in the 9th century B.C. because of the date of the graffiti found by the expedition at Timnah. Qataban appears to have come to an end somewhere between 125 and 75 B.C.

The south Arabian inscriptions appear to be of west Semitic origin and number many thousands. They consist chiefly of dedications, building inscriptions, and invocations, but many are as yet unpublished. The first copies reached England in 1837 as a result of the work of Lieut. J. R. Wellsted, but the majority were collected by J. Halévy and É. Glaser between 1869 and 1894. The south Arabian script was deciphered by E. Rödiger and W. Gesenius. (M. V. S.-W.)

VI. HISTORY

A. Pre-Islamic Arabia

Before the rise of Islam (and to some extent after as well) the term "Arab" meant preeminently the Bedouin nomads who inhabited the desert tracts which form the core of the peninsula, with a tongue stretching northward into what is now the Syrian Desert between Damascus and the Euphrates Valley; the term did not apply to the settled populations of the southwest or to those of the townships and oases along the west coast. The historical significance of the Bedouins lay chiefly in the raids they were constantly making on the settled folk around the fringes of the desert. It is this recurrent pattern of incursions from the desert into the sown that led L. Caetani and others to formulate the hypothesis that Arabia was the original home of the Semites and that the village and urban populations of Semitic culture in the Fertile Crescent (the lands of the eastern Mediterranean littoral and the Euphrates Valley) represent an overspill of desert nomads who had become settled. With some modifications, this hypothesis was also advanced by S. Moscati (*Chi furono gli Semiti?*, 1957), who, however, emphasizes that in this context "original" means only as far back as present data make it possible to trace ethnological features and that the settlers have become closely intermingled with other strains. A subsidiary hypothesis—that central Arabia was formerly more fertile than it is now and that it was the process of desiccation which forced the current of emigration outward into the surrounding lands—is, as Moscati allows, hardly tenable. It is true that the configuration of the peninsula shows that at one time considerably more water flowed there than ever does now. But such a time was almost certainly in a remote past, and within historical times it is improbable that there has been any significant climatic change. To this and related problems of Arabian prehistory, however, no final answer will be possible until the archaeological exploration of the peninsula, still in its infancy, has progressed much further.

1. Early Civilization in the South.—More than a millennium before the rise of Islam there flourished in the mountainous southwestern corner of the peninsula a native civilization of a high order, which has left as its evidences the ruins of massive buildings and extensive irrigation works and, above all, a wealth of inscriptions in a language which forms a separate branch of the Semitic linguistic family (distinct from Arabic) and was written with its own alphabet. This culture had trade links across the Indian Ocean, though it is altogether uncertain when these began; it had close links with the part of Africa lying immediately opposite, although the civilization of this latter area seems, from what little is known of its earliest phases, to be an offshoot of south Arabian culture rather than an independent phenomenon; and there are sporadic traces of contacts with Egypt. But the civilization with which the south Arabian culture had by far the most marked affinities is that of the Semitic populations of the northern Fertile Crescent, to such an extent that a common origin seems certain. A few odd features inexplicable on a Semitic basis could be regarded as relics of a pre-Semitic past, if the hypothesis of C. S. Coon were accepted—that the shores of the Indian Ocean were once inhabited by a race which was pushed back by invasions from the north into a few remote pockets, represented by the Veddas of Ceylon and the cow-raising peoples of the Mahrah country of southern Arabia, who are noticeably different from the peoples of the rest of the peninsula with their marked affinity to the northern Semites. Viewed overall, the south Arabian culture is unmistakably Semitic. Nevertheless, in certain limited aspects of life, Greek influence made itself felt. Coinage, for instance, first introduced into southern Arabia in about the 4th century B.C., is from first to last modeled on Greek prototypes; and from at least the 1st century B.C., the plastic art of southern Arabia is strongly subjected to Hellenistic influences.

In spite of a considerable mass of epigraphic texts, scholars are severely handicapped in arranging and interpreting this material by the almost total lack of cross checks in the form of references to Arabian events in the literature of the ancient world outside Arabia. The Greek geographers possessed some data about the peninsula, gathered largely no doubt from the traders from both northern and southern Arabia who made their appearance in the markets of the Mediterranean world. But of the march of events in Arabia the outside world seems to have known virtually nothing until the 6th century A.D. As a result, a controversy exists over the problems of the internal chronology of the Arabian epigraphic sources. Only on one occasion in recorded history did the Mediterranean world attempt to take a direct hand in ancient southern Arabia, with the Roman expedition in 25–24 B.C. under Aelius

Gallus, which perished miserably on the threshold of the south Arabian culture area; yet even in this case it has proved impossible to trace in the south Arabian inscriptions any absolutely certain allusion to this expedition and thereby obtain a cross reference as a basis for the internal chronology of the inscriptions.

2. The South Arabian Kingdoms.—The Greek geographer Eratosthenes (3rd–2nd century B.C.) tells of a fourfold political division of southern Arabia between Minaeans, Sabaeans, Qatabanians, and Hadhramautites. This is confirmed by the inscriptions, which attest four principal kingdoms, each with its own dialect, corresponding to those of Eratosthenes.

The Minaean kingdom had its centre in the lower Wadi al Jawf at Qarnau (now called Ma'in, in northern Yemen). According to a view of which the main proponent was F. Hommel, the whole period of the Minaean kingdom antedated the 6th century B.C., and its beginnings stretched back to around 1200 B.C. Hommel's views have been widely copied in books by nonspecialists, but research since 1937 has conclusively invalidated them and showed that the flourishing period of the Minaean kingdom, insofar as it is attested by the inscriptions, was approximately the 4th to 2nd centuries B.C. It is therefore the period of the early Sabaean inscriptions which constitutes the beginning of written records of south Arabian culture. This has been variously dated to around the 8th or to the 5th century B.C.; in either case there must have been several centuries of evolution preceding the written records, since these present a picture of an already fully developed civilization.

The Minaeans were never a territorial power of great significance. They appear rather to have been a community of traders, as was the population of Mecca in the 6th century A.D. Nearly the whole body of Minaean inscriptional material comes from a narrowly limited range of sites: Qarnau and Yathil (now Beraqish), both close together in the lower Wadi al Jawf, south of Najran; and Dedan (now Al 'Ula in northern Hejaz), where the Minaeans had a colony. The actual territorial area under their sovereignty seems to have been small.

For the kingdom of the Sabaeans, with its capital (at least in the earlier period) at Ma'rib (in eastern Yemen), *see* SABAEANS.

Qataban was centred in Bayhan or Beihan and the adjoining areas. The kingdom flourished from approximately the 5th century B.C. (perhaps somewhat earlier) to the turn of the era. Its capital, Timnah, was destroyed shortly before or shortly after the beginning of the Christian era, and the political fate of the former Qatabanian dominion thereafter is obscure. One text of probably the 1st century A.D. suggests that the Wadi Bayhan was then under the suzerainty of Hadhramaut, but in texts of the following centuries from this area a strong Sabaean dialectal influence is perceptible and it is likely that Saba (Sheba) absorbed it sooner or later in the first Christian centuries.

Hadhramaut had its capital at Shabwah, near the head of Wadi Hadhramaut, and its area spread between there and the sea. It maintained its political independence down to the end of the 3rd century A.D. but was then absorbed by Saba. It is uncertain whether the Ethiopian domination of southern Arabia, which lasted for some decades in the middle of the 4th century A.D., included Hadhramaut, or whether the latter during this interlude regained its independence; but by the end of the 4th century the restored Sabaean kingdom again included Hadhramaut.

A fifth power which made its appearance on the south Arabian political scene about the beginning of the Christian era was that of the tribe of Himyar. The first mention of this tribe, whose original habitat was on the coast rather west of Al Mukalla, shows them in conflict with the kingdom of Hadhramaut in the 3rd or 2nd century B.C. But a Greek source of the 1st century A.D. states that at that time there was a sort of dual monarchy of Saba and Himyar, with the royal residence located at Zufar in the southern Yemeni highlands instead of at the old Sabaean capital of Ma'rib. Himyar figures in the Greek accounts as the "Homerites." In succeeding centuries Himyar seems to have become the dominant element in south Arabian affairs, for the Christian Greek authors commonly refer to the people of southern Arabia as a whole as Homerites and the Islamic authors apply the term Himyarite to all pre-Islamic south Arabian antiquities. Yet the tribal name Himyar never appears in the official title of south Arabian monarchs; "king of Saba" was to the last the first element of the title, to which was added in the early centuries A.D. "and of the Raidan territory," and from the end of the 3rd century (apart from the 4th-century episode of Ethiopian domination) the further addition "and of Hadhramaut and Yemen."

Viewed overall, the pre-Islamic history of southern Arabia is thus one of Sabaean expansion. The kingdom of Saba began by absorbing several petty kingdoms in the near vicinity of Ma'rib, and then gradually over the centuries absorbed the territories of the rival kingdoms of Ma'in, Qataban, and Hadhramaut. By the 5th–6th centuries A.D. the ancient kingdoms and political boundaries had vanished, and the entire south Arabian culture area was under a unified political control which (whatever the actual position of Himyar in it may have been) saw itself as the historical successor to the ancient Sabaean kingdom. Moreover, the earlier isolation of the area now began to break up, and southern Arabia more and more tended to play a part in the political affairs of northern Arabia and the Mediterranean world.

3. The Kingdoms of Central and Northern Arabia.—Information about this area in the early period, down to about the 2nd century B.C., is extremely scanty. It is clear that such culture as it possessed was vastly inferior to that of southern Arabia on the one side and the Fertile Crescent on the other. Throughout the middle part of the 1st millennium B.C. it seems to have been merely a "buffer area" between those two cultures and subject to influences from both. But it is noteworthy that all the pre-Islamic inscriptions of the peninsula (apart from the extreme northwestern sector) are in scripts closely akin to the south Arabian alphabet rather than to the Aramaic types of script prevalent in the Fertile Crescent which are the ancestors of the ordinary Arabic script of today.

In the late 8th century B.C. Assyrian records mention certain "queens of the Aribi," the Aribi being obviously nomad Bedouin confederations of northen Arabia; but these have left no certainly identifiable written records of their own. The oasis of Tayma' emerged briefly into the limelight of history when the neo-Babylonian monarch Nabonidus (*q.v.*) made his residence there for part of his reign.

Perhaps round the 2nd century B.C. a kingdom of Dedan (Al 'Ula; *see* above) had an ephemeral existence, to be succeeded by a kingdom of Lihyan which maintained a governor in Dedan and may have been centred somewhere in the same area; this seems to have flourished in the centuries immediately preceding and following the Christian era. About the same time there also flourished the Nabataean kingdom centred in Petra (southern Jordan; *see* NABATAEANS); but the latter belongs rather to the orbit of the Mediterranean world, for its inscriptions are Aramaic in language and script, in spite of the fact that the majority of the population probably spoke a dialect akin to Arabic. The same remark applies to the Palmyrene kingdom in the 3rd century A.D., whose most famous monarch was Queen Zenobia (*q.v.*).

In northwestern Arabia, after the disappearance of the Nabataean kingdom, a certain Imru' al-Qays, son of 'Amr, who died in A.D. 328, claimed the title of "king over all the Arabs" (*i.e.*, Bedouins). Although he campaigned as far south as Najran, the actually effective extent of his dominance is altogether uncertain.

Somewhere around the middle of the 4th century A.D. a section of the tribe of Kinda emigrated from southern Arabia and settled in central Arabia southeast of Mecca under the rule of a succession of petty kings. In the latter half of the 5th century the kings of Kinda established a hegemony over most of central Arabia. At the same time they maintained their ancestral connection with southern Arabia, and the kingdom was always within the political orbit of the south. The Kinda hegemony broke up early in the 6th century as the result of a disastrous war with Hira, and the remnants of the tribe returned to southern Arabia.

The kingdom of Hira (*q.v.*), in northeastern Arabia, flourished under the Lakhmid dynasty, from the end of the 3rd to the end of the 6th century A.D., and normally aligned itself with Sasanian Persia. A counterpoise to Hira in the northwest was furnished by the kingdom of Ghassan (east of the Jordan River), under rulers

of the house of Jafna, which allied itself with Byzantium; but the history of this kingdom belongs rather to the 6th century.

4. 6th Century A.D.—Early in this century the Arabian Peninsula emerged from its isolation and began to take a part in world affairs. Ghassan and Hira played an important role in the strategy of the intermittent wars between Byzantium and the Sasanian empire.

Southern Arabia, by the end of the 4th century A.D., had abandoned its ancient polytheism in favour of a monotheistic cult of a supreme deity under the name of Rahman, "the merciful." The exact nature of this cult is uncertain; specifically recognizable Jewish and Christian formularies do not appear in the texts until the 6th century. Early in the 3rd decade of that century, however, the south Arabian king, who is said to have professed Judaism, pursued a policy of persecution of the Christians in his dominions, culminating in a massacre of them at Najran (Nagran). This caused a profound shock throughout the Christian world and has left a large martyrological literature in Greek, Syriac, and Ethiopic. Byzantium seized this as an excuse to incite the Christian king of Aksum in Ethiopia to invade southern Arabia; the Greek historian Procopius alleges that the real motive behind this was to draw southern Arabia into the Byzantine political orbit and thereby secure access to the markets of India over a route bypassing the trade channels running through Sasanian dominions. The invasion was successful, the persecutor killed, and a Christian puppet ruler, subject to Aksum, set up. But his reign lasted only a few years, after which he was dethroned by a native rising which placed on the throne Abraha (or Abreha; also a Christian, but possibly of Nestorian tendencies in opposition to the Monophysite doctrine prevalent in Ethiopia), whose long and successful reign was the last flowering of the millennium-old south Arabian sovereignty. By cautious diplomacy, Abraha seems to have early shaken off allegiance to Aksum and maintained southern Arabia in a precarious independence between the powers of Byzantium, Ethiopia, and Iran. He also made military expeditions deep into the heart of central Arabia, bringing him up to the frontiers of Hira, and executed repairs on a vast scale to the great irrigation installations of Ma'rib. But a few years after his death (perhaps around A.D. 570) his kingdom collapsed and southern Arabia was subjected to Iranian occupation for some years; it never regained a unified independence.

The closing years of the century also saw the fragmentation of the kingdom of Ghassan and the decline of the power of Hira. At the opening of the 7th century Arabia was a mass of petty autonomies with no unifying focus. (A. F. L. B.)

B. Muslim Arabia, to the Rise of the Wahhabis

1. The Rise of Islam.—The history of Arabia after the advent of Mohammed (*q.v.*) and the spread of his teaching (*see* Islam) at first followed much the same general lines as in the days of the *Jahiliyah* ("ignorance"). The tribal structure of Arab society remained unchanged and continued to prescribe its horizon and limit its loyalty. The restraints of a central authority emanating from a capital, near or remote, were quite contrary to the Arab way of life and were accepted only under compulsion. The Prophet was well aware of this characteristic of the Bedouins, and the Koran described them as "the worst in unbelief and hypocrisy" (9:97). However, by the ninth year of the Hegira (*q.v.*), Mohammed was able to exact from the majority of the tribes nominal adherence to Islam and, what was more important, payment of the *zakat* tax, with its implication of submission to the rising hegemony of Medina. On his death (A.D. 632), many of those tribes, as well as those which never had acquiesced in Islamic power, seized the opportunity to reassert their independence and the former stopped payment of the *zakat*. In Yemen and Hadhramaut in the south, in Oman and Bahrain in the east, in Al Yamamah (Al Kharj; *q.v.*) and Kinda in central Arabia, and even in Hejaz itself, dissident tribes rose in revolt. At least four rival prophets appeared, but Abu Bakr (*q.v.*), the first caliph (632–634), proved equal to this first important crisis in the life of the new faith since the founder's death. His reign was mostly occupied with *ridda* ("secession," "apostasy") wars, waged not only to bring secessionists back within the fold of Islam but also to win over many who had previously been outside the faith. The brilliant generalship of Khalid ibn al-Walid, backed by the energetic determination of the caliph, ensured complete victory. Arabia was united in a common fraternity; administratively it was divided into ten provinces, each headed by a provincial governor directly responsible to the caliph himself. (*See* further Caliphate.)

The warlike spirit of the tribes, now unable to find expression in intertribal raids, had to be channeled into new outlets outside the peninsula. This step, in all likelihood contemplated by the Prophet, became Abu Bakr's next objective. He therefore dispatched three detachments of about 3,000 men each to start operations in southern and southeastern Syria. But he died (A.D. 634) before he could witness the results of this fateful adventure.

The conquests Abu Bakr started were carried forward by his successor Omar I (*q.v.*; 'Umar), during whose reign (634–644) Arab arms wrested Egypt and Syria from the Byzantine emperor, destroyed the Sasanian empire, and annexed Iraq and Persia to the fast-growing Arab domains. A year before Omar's death in 644, his armies were at the border of India.

Meanwhile, Omar strengthened the hold of the central administration over the peninsula and initiated a policy of making it an all-Muslim country. Non-Muslim communities, however, survived in different areas for several centuries. Omar also addressed himself to the problem of administering the vast territories acquired by conquest. His "reforms" emphasized Arabism, according Arabs a privileged position in the empire, but secured for non-Arab Muslims a status superior to that of non-Muslims. Omar's extreme Arabism may have been partly responsible for his assassination by a disgruntled neo-Muslim.

With his successor, Othman (*q.v.*; 'Uthman), who reigned from 644 to 656, the old Meccan aristocracy, whose predatory predilections were held in check by the strong hand of Omar, was able to reassert itself. Furthermore, the conquests, which absorbed the energies of the tribes and well-nigh exhausted their manpower, came to a temporary standstill. The return to near normality in the peninsula helped to focus attention on internal affairs. Tribal jealousy of the privileged position of the Quraysh (the clan of the Prophet), Arab deep-seated dislike of governmental authority, dissatisfaction in the occupied territories against the growing control of Medina, and rivalries among leading members of the Quraysh combined to precipitate civil war which led to the assassination in 656 of Othman, whose greatest achievement had been the codification of the Koran. The unity of the peninsula, achieved by the first caliph and strengthened by the second, thus came to an abrupt end under the third.

The rift among the aspirants to the caliphal throne widened with the election of 'Ali (*q.v.*), Mohammed's first cousin and son-in-law, who reigned from 656 to 661. Mohammed's widow, 'A'isha, and two of his companions, Talha and al-Zubayr, refused to swear allegiance to the new caliph and rose in rebellion. 'Ali defeated the rebels at the "battle of the camel" and won Iraq, where he established his capital. This marked the beginning of the final recession of Arabia to a secondary position in the Islamic empire. Stubborn resistance, however, came from Damascus, where the provincial governor, Mu'awiya, raised the flag of rebellion, accusing 'Ali of complicity in the murder of Othman. Because of his inability to hold the support of his followers for his policies, 'Ali was never able to follow up his initial successes against Mu'awiya, and after the Battle of Siffin (657) he allowed himself to be tricked by the ruse of the arbitration. His assassination in 661 made Mu'awiya's military and political victory complete and ushered in Omayyad rule of the peninsula from the new capital, Damascus.

2. The Omayyad Dynasty.—The new caliph had no difficulty in securing the abdication of 'Ali's eldest son, Hasan, whom the 'Alids set up as caliph in Kufa, or in reuniting the peninsula, which became simply a province in his vast empire. At the death of Mu'awiya I (680) and the accession of his son Yazid I, however, trouble broke out again. 'Ali's second son, Husain, embarked on an ill-advised adventure against the Omayyads; the little support he was able to muster in Kufa soon vanished, and he met his death

in the same year at Karbala, bequeathing to the Shi'ites an enduring battle cry and to the community of Islam its greatest schism (*see* HASAN AND HUSAIN). It was, however, at Yazid's death that Omayyad (Umayyad) power in Arabia received its gravest challenge, when, for nine years (683–692), 'Abdullah ibn al-Zubayr held the title and power of caliph and received the allegiance of nearly every quarter of Islam.

Both the Omayyads and Ibn al-Zubayr had to contend with the turbulent Kharijite sect (*see* KHARIJITES), which, under Najdah ibn 'Amir of the Banu-Hanifa, threatened to dominate a large part of the peninsula until Ibn 'Amir was overthrown by another Kharijite, Abu Fudayk. During the reign of 'Abd al-Malik (685–705), an Omayyad army under al-Hajjaj crushed Ibn al-Zubayr and another army destroyed Kharijite power in eastern Arabia. Thereafter, until the last years of the dynasty, Omayyad authority in Arabia was unchallenged. The rivalry of the Qays (Kais) (north Arabian) and Yemeni (south Arabian) tribes, however, continued to be felt. This had plagued Omayyad rule since the times of Mu'awiya I, who had leaned heavily on Yemen. The struggle between the two factions flared up again at the death of Mu'awiya II, but Marwan I succeeded in defeating the Qays at the battle of Marj Rahit (684). Enmity between the two groups continued, largely contributing to the fall of the dynasty in 750.

3. The Abbasid Dynasty.—With the coming of the Abbasids, stubborn remnants of the Kharijites known as the Ibadiya established their own imamate in Oman under al-Julanda ibn Mas'ud. Though crushed by Abbasid arms in 752, they were able to revive their imamate in this remote part of the peninsula, whence they spread to Zanzibar and even to North Africa. Trouble broke out also in Medina, where the 'Alids, who thought that the overthrow of the Omayyads presaged an 'Alid restoration, refused to submit to their Abbasid cousins. The precautionary steps taken by the Abbasid governor of Medina precipitated, late in 762, an 'Alid rebellion on behalf of the Hasanid pretender, Mohammed al-Nafs al-Zakiyah. The caliph al-Mansur had no difficulty in crushing the movement but treated the city of the Prophet itself gently. In fact the Abbasids made a point of favouring the two holy cities of Islam to gain popular acclaim among the faithful. Another Hasanid rebellion flared up during the reign of al-Hadi, but was easily put down in 786 at Fakhkh, near Mecca.

'Alid discontent continued to plague the Abbasids. One pretender followed another but their only success was in Yemen. In the early 9th century the struggle for the caliphate between al-Amin and al-Ma'mun favoured such adventures. Al-Ma'mun attempted to appease 'Alid sentiment by designating an 'Alid as his successor and substituted the 'Alid green for the Abbasid black as the royal colours, but with the death of his 'Alid candidate in 818 he withdrew his support. He then tried to deal with the situation by force. Mohammed, his able viceroy in Yemen, defeated the 'Alid rulers there but soon established his own Ziyadid dynasty (820) at Zabid, according the caliph only nominal allegiance. Abbasid attempts to control the peninsula were successful under al-Wathik (842–847), but the situation deteriorated under his successor, al-Mutawakkil (847–861). Toward the end of his reign, the Ya'furids established themselves in San'a' (861). Later the Banu-al-Ukhaydir seized Al Yamamah (*c.* 864) and the Zaidite Rassids seized Sada (*c.* 894). A more serious danger to the empire arose when a certain 'Ali ibn Mohammed who claimed 'Alid descent stirred up the Negro (Zanj) labourers in the salt marshes of southern Iraq in a rebellion (869–883) which spread as far as the two holy cities before it was finally suppressed.

While the central authorities were occupied with the Zanj rebellion, other 'Alids were active in other parts of the peninsula. Isma'ilism found a fertile soil in southern Arabia, where toward the end of the 9th and beginning of the 10th century the chief propagandist (*da'i*) of the Fatimids, Abu 'Abdullah al-Husain al-Shi'i, made his appearance (*see* ISMA'ILISM; FATIMIDS). His missionary labours during the pilgrimage among members of the Kitama Berber tribes ensured support in North Africa for the Fatimids. More serious, however, was the danger in eastern Arabia where, under Abu Sa'id al-Jannabi (fl. *c.* 900) and his son Abu Tahir Sulayman (914–944), the Isma'ilite Karmatians were able to organize a state which for many years was a cause of severe disturbance to the caliphate. Under Ibn Zikrawayh they had already, in 900, moved against Syria, defeated the Tulunids, and laid siege to Damascus. The Abbasids restored their authority over Syria, but the Karmatians in eastern Arabia proved more difficult to suppress. In 930 Sulayman occupied Mecca and carried the sacred Black Stone (*see* KA'BA) off to his capital, Hajar. It was not restored till 20 years later at the behest of the Fatimid ruler al-Mansur, with whom the Karmatians were allied against Baghdad. When the Fatimids occupied Egypt (969), the Karmatians switched to the support of the Buyids. Gradually the Karmatians were forced back to Al Hasa, and their designs on Baghdad were checked by the Buyids.

As the Buyids (*q.v.*) with their Shi'ite leanings reduced the power of the caliphate and Fatimid influence increased, the power of the Abbasid dynasty began to disintegrate, especially in the outlying districts of the empire. In the peninsula the tribal spirit, which had been temporarily checked by Islam, was reasserting itself, and human resources, which had been drained by the conquests and civil wars, were regaining their strength and restiveness. In spite of the arrival of the Seljuks in Baghdad (1055), which gave the empire a new lease on life, petty dynasts continued to appear in different parts of Arabia. (*See* also ABBASIDS.)

4. Minor Dynasties.—In the 11th and 12th centuries the Shi'ite Sulayhids in San'a' were supplanted by the Hamdanids; the Najahids in Zabid gave way to the Kharijite Mahdids; the Isma'ili Zurayids asserted their independence in Aden; while the Zaidite Rassids continued to hold their own in Sada. Oman, Bahrain, and Al Hasa were successfully cleared of the Karmatians. In Mecca a Hasanid dynasty established sharifian rule, and a Husainid dynasty ruled in Medina. Once again tribal loyalties and rivalries dominated the entire area. In 1174, only three years after he had destroyed Fatimid power in Egypt, Saladin moved into Arabia and toppled most of the native dynasties. (*See* SALADIN; AYYUBIDS.) Only the Zaidites survived. Ayyubid rule meant the triumph of Sunnism over Shi'ism throughout the peninsula. Mecca recognized Saladin as sovereign, and he dispatched his brother Turan Shah to occupy Yemen. Turan Shah suppressed the Hamdanids of San'a', the Mahdids of Zabid, and the Zurayids of Aden, and for over half a century (1173–1228) Yemen remained in Ayyubid hands.

On the death of the last Ayyubid ruler in Yemen, his governor of Mecca, 'Ali ibn Rasul, succeeded his master in the government of all the country and established the so-called Rasulid dynasty which extended its control from Hadhramaut to Mecca and maintained its power for over two centuries (1229–1454). At the execution (1258) of the last Abbasid caliph by the Mongol conqueror Hulagu, the second Rasulid ruler assumed the title of caliph; but the Mameluke sultans, whose power in Egypt was increasing, assumed nominal overlordship over the holy cities of Islam and had their own plans for the restoration of the caliphate.

5. The Mamelukes and the Ottoman Turks.—Disturbances in Mecca around the middle of the 14th century offered the Mamelukes (*q.v.*) an opportunity to intervene and dealt a heavy blow to Rasulid power. The eighth Rasulid ruler, Ahmad ibn Isma'il (who reigned from 1400–24), regained temporary control and offered Mameluke trade in the Red Sea keen competition, but soon after his death the dynasty fell. The Rasulids were succeeded by the Tahirids (1446–1517), who maintained their authority until the conquest of Arabia by the last Mameluke of Egypt, Kansu al-Ghuri (who reigned from 1501 to 1516). In the following year (1517) the Ottoman sultan, Selim I (reigned 1512–20), assumed the title of *Khadim al-Haramayn* (servant of the two sanctuaries), but Ottoman authority over Hejaz and Yemen was not established until the reign of Selim's son and successor, Suleiman I the Magnificent (reigned 1520–66). Even then stubborn resistance to Ottoman rule continued, especially under the Zaidite imams who succeeded in 1635 in forcing the Ottomans out of Yemen.

Ten years before Selim I assumed titular authority over the holy land of Islam, eastern Arabia witnessed the first European incursion into Arabian territory proper since the ill-fated Roman

expedition of Aelius Gallus in 25–24 B.C. This was the capture of Oman by the Portuguese in 1508. The remaining years of the century saw Dutch-Portuguese rivalry for trade in the Persian Gulf intensified. In the early 17th century both rivals were displaced by English traders of the East India Company, who allied themselves with the Persians.

At this time the rising power of the Safavid dynasty in Persia and the increasing problems the Ottomans had to face in Europe weakened the Ottoman hold on Arabia and enabled local chiefs to assert their power. Not only were the imams of San'a' able to drive the Ottomans out of Yemen but Hejaz also became practically independent under its sharifian rulers. In the east, the Ibadi Ya'rubids (1624–1741) established themselves in Oman and succeeded in driving the Portuguese out of Muscat. Other Bedouin chiefs drove the Ottomans out of Al Hasa and dominated the grazing grounds of the area until the last quarter of the 19th century.

Except for Yemen, which was at that time controlled by the San'a' imams, and Hejaz, which in spite of nominal Ottoman suzerainty was practically independent, the peninsula reverted to its time-honoured pattern of tribal rivalry and strife. It was in these circumstances that the rivalry between two rather insignificant princes in Wadi Hanifah, the rulers of Al 'Uyaynah and Dar'iya, was destined to serve as the background for a reform movement which ushered in a new era for the peninsula.

(N. A. F.)

C. The Wahhabi Movement

1. Origins and Early Expansion.—Mohammed ibn 'Abd al-Wahhab, the founder of the Wahhabi (*q.v.*) movement, was born in Al 'Uyaynah in 1703 and as a young man traveled widely in Iraq, Syria, and other countries of the Middle East. It was upon his return to Al 'Uyaynah (*c.* 1750) that he first began to preach his revolutionary ideas of religious reformation on puritan lines. The laxity and backsliding of the Arabs in religious matters were at this time notorious; and Mohammed's aim was to restore the practices and precepts of primitive Islam among his countrymen. His teaching was influenced by that of Ibn Taimiya (*q.v.*), whose efforts to revive the puritanical doctrines of the Hanbalite school had resulted in his death in a Syrian prison in 1328. It was among his own fellow citizens of Al 'Uyaynah that Mohammed ibn 'Abd al-Wahhab decided to open his campaign.

The ruler of Al 'Uyaynah, Othman ibn Mu-'ammar, gladly welcomed the returning prodigal and even adhered to his doctrines. But the temper of the people was less complaisant, and Mohammed's preaching and sincerity were put to a number of severe tests. From these he did not flinch, but Othman now received threats from the Banu-Khalid chief of Al Hasa, demanding the death of the innovator on pain of withholding annual gifts from the province, and even of invasion.

Othman, unable to face the risks of financial loss and actual danger, but unwilling to kill his guest, decided to dismiss Mohammed from his territory, leaving it to him to choose his destination. He chose Dar'iya, the seat of Mohammed ibn Sa'ud, some 40 mi. downstream in Wadi Hanifah; and thither he was sent under escort, walking the whole way. Othman soon had reason to regret his action and to remember the words spoken to him by Mohammed on his first arrival at his court: "I hope," he had said, "that, if you rise in support of the one and only God, God Almighty will advance you, and grant you the kingdom of Najd and its Arabs!" Othman had thrown away the chance of making Al 'Uyaynah the capital of an Arab empire; and his later invitation to Mohammed to return was duly declined by the latter, who had transferred his prophetic blessing to his new protector.

The people flocked to the teaching of the new "prophet" (he himself never claimed such a title), conducted at first discreetly on the outskirts of the capital. Women were among his earliest proselytes, including Mudhi, the wife of Mohammed ibn Sa'ud, to whom she introduced the preacher. The latter was then installed in more comfortable quarters in the town itself; and the alliance of priest and prince, duly sealed by mutual oaths of loyalty, soon began to prosper in terms of military success and expansion. The parochial wars of old continued in the new guise of a crusade against the infidel—a term which specifically included all who held aloof from the Wahhabi interpretation of God's will as preached by the founder of Islam.

One by one the enemies of the new dispensation were swept into oblivion. The earliest conquests brought Al 'Uyaynah and Al Hasa under Wahhabi control; but Riyadh and Manfuhah maintained their stubborn resistance for 20 years before succumbing to the steady pressure of the new movement. An invasion in force of the Sa'udi realm by the Makarima (Isma'ili) chief of Najran threatened the stability of the regime for a time; but it ended in a pact of mutual nonaggression, and the invaders withdrew. And by 1765, when Mohammed ibn Sa'ud died, the whole of central and eastern Arabia, in spite of sporadic dissident movements, had fallen under more or less effective Wahhabi rule.

Sa'ud's son and successor, 'Abd al-'Aziz I, who had been largely responsible for this extension of his father's realm by his exploits as commander in chief of the Wahhabi forces, continued to work in complete harmony with Mohammed ibn 'Abd al-Wahhab. It was indeed the latter who virtually controlled the civil administration of the country, while 'Abd al-'Aziz himself, later in cooperation with his warlike son, Sa'ud II, busied himself in the expansion of his empire far beyond the limits inherited by him. In particular, his attacks on the pilgrim caravans crossing Arabia had begun to attract the attention of the Turkish government, and in 1798 a Turkish force invaded Al Hasa, though it was compelled to withdraw.

2. Struggle with the Ottomans.—The Wahhabis retaliated in 1801 with the capture and sack of the Shi'ite holy city of Karbala in Turkish Iraq; and the following year Sa'ud led his father's army to the capture of Mecca itself in Turkish Hejaz. It was soon after his return from this expedition that his father was assassinated by a Shi'ite fanatic in the mosque of Dar'iya in revenge for the desecration of Karbala.

The issue was now fairly joined between the Ottoman caliphate and the fanatical Wahhabis of Arabia. Meanwhile, in 1792, the venerable Mohammed ibn 'Abd al-Wahhab had died at the age of 89 after a faithful ministry of nearly 50 years, bequeathing to his temporal and spiritual successors the divine cause to which he had dedicated his life. They did not fail him; in 1804 Sa'ud captured Medina, and now the Wahhabi empire embraced the whole of Arabia down to Yemen and Oman. Year after year Sa'ud visited Mecca to preside over the pilgrimage as the imam of the Muslim congregation. But the tide was soon to turn to the disadvantage of the Wahhabis. The sultan of Turkey, preoccupied in other directions, consigned to Mohammed 'Ali Pasha, the virtually independent viceroy of Egypt, the task of crushing the "heretics." Sa'ud in 1811 was actually leading them against Baghdad when he received the news of an Egyptian landing in force on the Hejaz coast under the command of Tusun, the pasha's youthful son. Turning west, Sa'ud inflicted a severe defeat on the invaders; but reinforcements enabled Tusun to occupy Mecca and Medina in 1812. The following year Mohammed 'Ali assumed command of the expeditionary force in person, but in 1814 his son suffered a severe defeat near At Ta'if, which was, however, offset by the death of Sa'ud at Dar'iya in the same year.

Sa'ud's son, 'Abdullah I, was scarcely of his father's calibre, and the capture of Ar Ra's in Al Qasim by the Egyptians in 1815 forced him to sue for peace. This was duly arranged and the enemy withdrew from Najd; but the truce was short-lived, and in 1816 the struggle was renewed, with Ibrahim Pasha, another of the viceroy's sons, in command of the Egyptian forces. Gaining the support of the volatile tribes by skilful diplomacy and lavish gifts, he advanced into central Arabia, bypassing Ar Ra's after an unsuccessful siege of four months to occupy 'Unayzah and Buraydah, the two principal towns of Al Qasim, and to capture Ash Shaqra' after a short siege. Joined now by most of the principal tribes (Harb and 'Utaiba, Mutair and Banu-Khalid), he appeared before Dar'iya in April 1818. Desultory but desperate fighting among the palm groves of the Wahhabi capital ended six months later in the surrender of 'Abdullah, who was sent to Constantinople and there beheaded. Dar'iya was razed to the ground and Egyptian gar-

risons were posted to the principal towns. The Sa'udi family had suffered heavy losses during the fighting. A few had managed to escape before the surrender; the rest were sent to Egypt for detention. The Wahhabi empire had ceased to exist, but the scattered embers of the puritan fire smoldered on in the desert spaces in defiance of the new rulers of the land.

Matters came to a head in 1824 when Turki, a grandson of Mohammed ibn Sa'ud, succeeded in capturing Riyadh and expelling the Egyptian garrison. By accepting the nominal suzerainty of Egypt and agreeing to pay an annual tribute, he was left in peace to consolidate the new Wahhabi regime, with its capital at Riyadh. In 1834, however, he was murdered by an ambitious cousin, a son of Sa'ud II named Mishari. The latter was deposed and executed by Turki's son Faisal, who refused to pay the Egyptian tribute. In 1838 an Egyptian expeditionary force besieged Riyadh, and Faisal, duly deposed, was sent to serve a prison sentence in the citadel of Cairo, while Khalid, another son of Sa'ud II, was installed as ruler of Najd. Both Faisal and Khalid had been carried away into captivity in Egypt after the fall of Dar'iya, but the former had escaped in 1828 to rejoin his father and to play a prominent part in the reestablishment of the Wahhabi regime. Khalid had been released from prison to accompany the expeditionary force sent to restore Egyptian rule in Arabia as the ruler designate, on his undertaking to recognize the suzerainty of Egypt. So Faisal returned to Cairo for a second period of incarceration until his second escape and return to Najd in 1843.

Meanwhile the subservience of Khalid to his Egyptian masters was increasingly resented by his Wahhabi subjects; and in 1841 his cousin, 'Abdullah ibn Thunaian, raised the standard of revolt. Riyadh was captured by a bold coup, and its Moroccan garrison was expelled. Meanwhile Khalid, who was in Al Hasa at the time, made a virtue of virtual necessity and fled by ship to Jidda, leaving the throne to the usurper. The latter, when Faisal reappeared in 1843, made a show of resistance, only to be overpowered and slain. So Faisal resumed his reign after an interruption of five years, to rule unchallenged till his death in 1865. A sturdy champion of militant religion, he was able to combine the defense of his uncompromising unitarian faith with the substantial expansion of his realm, though not to the limits achieved by Sa'ud II. Hejaz remained in Turkish hands, while northern Arabia (the province of Jabal Shammar) was virtually independent, acknowledging only the shadowy suzerainty of Riyadh. However, he reestablished his authority in Al Buraymi and the Oman hinterland and even extended his influence as far as Hadhramaut and the frontiers of Yemen.

In 1865, when his power was an acknowledged factor in Arabian politics, menacing even British interests on the Persian Gulf littoral, Faisal was visited in state by Sir Lewis Pelly, the British political resident for the Persian Gulf area, though no specific agreement seems to have materialized from their discussions. In that same year Faisal died—a blind old man, bigoted, fanatical, and uncompromising, surrounded by evil counselors and unhappy in his own family, with sons at daggers drawn with each other, ready to dispute the throne on their father's demise. His eldest son, 'Abdullah, succeeded to the throne, maintaining himself uneasily thereon against the open rebellion of his brother Sa'ud III for six years until his defeat at the Battle of Judah in 1871. 'Abdullah's flight from that field left Sa'ud in possession, but the next five years saw the throne change hands no less than seven times in favour of five different members of the Sa'udi family. Meanwhile 'Abdullah had appealed to the Turks in Baghdad, who readily came to his assistance but took advantage of the situation to occupy the province of Al Hasa for themselves—an occupation destined to last for 42 years.

3. Ibn Rashid.—Sa'ud III died of wounds in 1875, and after a brief interval of chaos 'Abdullah II returned to the throne the following year, only to find himself powerless in the presence of a greater man in the north, Mohammed ibn 'Abdullah al-Rashid, whose capital was at Ha'il and of whom Charles Doughty left a brilliant picture in his *Travels in Arabia Deserta*. (*See* Ibn Rashid.) Ibn Rashid had succeeded to the throne of his father, the founder of the Rashidi dynasty, after a short period of anarchy following upon the suicide of his eldest brother, Talal, in 1866 and the murder of his second brother, Mit'ab, by the sons of Talal soon afterward. Ibn Rashid's accession was marked by the spilling of royal blood on an impressive scale, but he made amends for the blood bath by the smooth and efficient administration which he succeeded in imposing on his realm at a time when chaos seemed to reign unchecked in the whole peninsula.

Ibn Rashid was undoubtedly the dominant factor in Arabian politics when 'Abdullah II ibn Sa'ud returned to Riyadh for his third spell of authority. At first Ibn Rashid refrained from any forward action, but he soon found himself forced to intervene in the chaotic affairs of the Wahhabi realm. And it was not long before 'Abdullah was "invited" to be the "guest" of Ibn Rashid at Ha'il, while a representative of Ibn Rashid was appointed governor of Riyadh. 'Abdullah's health now began to show serious signs of deterioration, and Ibn Rashid very generously not only allowed him to return to Riyadh but actually restored the throne to him unconditionally in 1889. 'Abdullah did not live long in enjoyment of his restoration, however; he died in the same year, leaving to his youngest brother, 'Abd al-Rahman, the almost hopeless task of saving the realm of their ancestors from its impending doom.

But 'Abd al-Rahman, the father of 'Abd al-'Aziz II, the greatest Arab ruler since the Prophet himself, was not of the calibre of his distinguished son and was soon embroiled in senseless hostilities with Ibn Rashid. The Battle of Al Mulaida (in Al Qasim) settled the issue between them decisively in 1891, and for the second time in the space of 70 years the Wahhabi state suffered eclipse. 'Abd al-Rahman fled with his family to take refuge in Kuwait as the guest of its rulers, and Mohammed ibn Rashid added the Wahhabi realm to his Shammar fief. At Ibn Rashid's death in 1897 the throne passed to his nephew, 'Abd al-'Aziz ibn Mit'ab, whose political acumen fell far short of his military prowess. By the turn of the century he had alienated the sympathies of all Najd. Meanwhile his namesake, 'Abd al-'Aziz ibn 'Abd al-Rahman, had taken full advantage of his enforced sojourn in Kuwait to imbibe from his host, Sheikh Mubarak ibn Sabah, a knowledge of world politics which was to stand him in good stead as soon as he was old enough to embark on an adventure destined to avenge in full the humiliations of the past.

Kuwait was at that time the cynosure of European imperialism. Its port was coveted by the Germans as the logical terminus of the Berlin-Baghdad Railway. Britain, long the dominant power in the Persian Gulf, naturally opposed a project which would result in the outflanking of its imperial communications. The Rashid coveted Kuwait as a desirable outlet for the commerce of Arabia and readily lent himself to the Turko-German designs on the port; but the British government made it abundantly clear that it would tolerate no interference with the "independence" of Kuwait. Thus Ibn Rashid's probing raids in that direction came to nothing; and in 1900 it was Sheikh Mubarak who, with the co-operation of 'Abd al-Rahman ibn Sa'ud, staged a counterattack on the enemy's territory, while the latter's son, 'Abd al-'Aziz, led a diversion against Riyadh. This expedition ended in a disastrous defeat in Al Qasim province.

The following year the young 'Abd al-'Aziz (he was about 21 years old) sallied out with a small force of 40 followers on what must have seemed a forlorn adventure. Keeping clear of Al Hasa, and gathering considerable tribal support on the way, he reached the neighbourhood of Riyadh with some 200 men on Jan. 10, 1902. On the 15th, with a select body of only 15 warriors, he scaled the walls of the capital, surprised and utterly defeated the Rashidi governor and his escort before the gate of the Mismak fort, and was gratefully hailed by the oppressed population as their ruler.

4. Ibn Saud.—Thus began a reign destined to be one of the most famous in Arabian history. (*See* Ibn Saud.) The following years witnessed the development of the struggle between the Rashidis, whose power was by no means spent and who received substantial help from the Turks in men and material, and the restored Saudi dynasty. In 1904, at the Battle of Bukairiya, the combined Rashidi and Turkish (eight regular battalions) force was utterly defeated by Ibn Saud (as 'Abd al-'Aziz ibn 'Abd al-Rahman ibn Faisal Al Sa'ud became generally known outside Arabia); and in agreement with him the Turks, accepting the new situation

withdrew all their troops from central Arabia. Ibn Rashid continued the struggle alone; but in 1906 he himself was killed at the battle of Raudhat al Muhanna, and thenceforth Ibn Saud remained the undisputed master of Arabia, excluding the Jabal Shammar fief of the Rashidis and the Turkish provinces of Al Hasa, Hejaz, and Yemen. His ambition of regaining the whole of the realm of his ancestors was not yet satisfied, but he bent himself to the task of achieving it.

Meanwhile he busied himself with the reorganization of the country's administration, including the inception of a scheme designed to ensure the stability and permanence of his regime. History had taught him that the Arabs had frequently been inspired to great achievements under the stimulus of religious fervour or of outstanding personal leadership, while the death of the leader or the cooling of religious zeal had invariably resulted in the dissipation of the gains achieved, a result of the volatile character of a mainly nomadic society. It was the foundations of Arab society which needed examination and strengthening; and it was to this task that he set his hand in 1912 with the establishment of the first *Ikhwan* ("brothers") colony on the desert wells of Artawiya, peopled entirely by Bedouins, and forming a militant cantonment based on agriculture and dedicated to the service of God and prince. Within the next decade nearly 100 similar colonies were founded on suitable sites throughout the country, providing Ibn Saud with a formidable territorial army of fanatics, destined to win for him the whole of Arabia except the British-protected coastal enclaves and Yemen.

Ibn Saud's first exploit was the spectacular conquest of Al Hasa province from the Turks in 1913. During World War I he was forced by circumstances to be relatively quiescent, though surrounded by enemies (for the Arab rising in Hejaz against the Turks in 1916, *see* HEJAZ). In 1919, however, he struck his first blow, against King Husain of Hejaz (*see* HUSAIN IBN 'ALI), whose army was annihilated at Turaba by the *Ikhwan*. In 1920 Ibn Saud's son Faisal (*q.v.*) captured the province of 'Asir between Hejaz and Yemen. In 1921 Ibn Saud defeated the forces of Ibn Rashid (Mohammed ibn Talal, the last Rashidi amir) and annexed the whole of northern Arabia, occupying Al Jawf and Wadi Sirhan in the following year. Sheikh Salim of Kuwait died in 1921, and his successor, Ahmad ibn Jabir, established friendly relations with Ibn Saud. Meanwhile King Husain's sons Faisal and 'Abdullah (*see* FAISAL I; 'ABDULLAH IBN HUSAIN) had been placed on the thrones of Iraq and Transjordan respectively by the British government, these territories, with Hejaz, forming a formidable British-protected cordon around the northern and western borders of the Wahhabi state, with the inevitable result of frequent frontier incidents.

In 1923 the British government invited all the rulers concerned in these sporadic hostilities to attend a conference at Kuwait and if possible to agree on a settlement of their differences. It also made it clear that the subsidies hitherto paid to Ibn Saud and King Husain would be terminated from the end of that financial year.

The conference ended in complete disagreement on all points, and in September 1924 the Wahhabis attacked Hejaz. They captured At Ta'if after a brief struggle and occupied Mecca without opposition. Ibn Saud then laid siege to Jidda and Medina, while King Husain abdicated his throne in favour of his son 'Ali, whose situation was virtually hopeless from the beginning. By the end of 1925 both Medina and Jidda had surrendered to Ibn Saud, King 'Ali having previously abdicated and departed from the country. Meanwhile the Aqaba-Ma'in district of northern Hejaz was occupied by British troops on behalf of Transjordan, to prevent its falling into Wahhabi hands, and, on Jan. 8, 1926, Ibn Saud, who had adopted the title of sultan of Najd in 1921 after the capture of Ha'il, was proclaimed king of Hejaz in the great mosque of Mecca. In 1927 he also changed his title of sultan to king of Najd and its dependencies, the two parts of his dual kingdom being administered for the time being as separate units. In the same year the treaty of Jidda, negotiated by him with Sir Gilbert Clayton, in supersession of the Hadda and Bahrah treaties of 1925, placed his relations with Great Britain on a permanent footing. The Soviet government was the first power to recognize him as king, the British government following soon after, as did other powers formerly in diplomatic contact with Hejaz. Thus for the first time Ibn Saud found himself in direct contact with international politics.

He also found himself in difficulties with the more fanatical elements of Najd, because of his association with infidel powers and his alleged complaisance in regard to the British-protected sharifian regimes in Iraq and Transjordan, which were still the objects of Wahhabi lust. Incidents on their frontiers created a state of virtual though undeclared war, in which British aircraft played a part in discouraging Wahhabi incursions. Ibn Saud also had on several occasions to deal sternly with the disobedience of his more fanatical *Ikhwan* leaders; and in vigorous operations during 1929–30 the leading opponents of his moderate policy, Faisal al-Dawish and Sultan ibn Bijad, were defeated and consigned to prison in Riyadh, where they died in due course. This was virtually the end of the *Ikhwan* movement in Najd. The stage was now set for a long period of tolerance and understanding between the new Arabia and the outside world, and for the unification in 1932 of the two parts of the dual monarchy under the name of Saudi Arabia.

ARABIA, ROMAN PROVINCE OF, extended from the west coast of the Sinai peninsula northeastward along the Palestinian-Syrian border to a line south of Damascus and southeastward down the east coast of the Red sea to Egra (Mada'in Salih in the Hejaz). It comprised the territory of the former kingdom of the Nabataeans (*q.v.*) with the addition of some adjacent cities, including Gerasa (modern Jerash, Jordan) and Philadelphia (Amman) from Roman Syria. The Roman conquest of the Nabataean kingdom—formally annexed by the emperor Trajan in A.D. 105—was effected by Cornelius Palma, legate of Syria. The province was governed by a *legatus Augusti* of praetorian rank, who commanded one legion. Bostra (*see* BOZRAH) in the extreme north was made the capital of the province and the legionary camp, but the old royal capital Petra remained the religious centre and was given the title of metropolis by Hadrian. A road was constructed by the legate Gaius Claudius Severus (111–114) "from the boundaries of Syria to the Red sea," linking Damascus via Bostra, Gerasa, Philadelphia and Petra to Aelana on the Gulf of Aqaba, and forts were built to control the Bedouin to the east. Much of the southern Arabian caravan and maritime trade in incense and other valuable commodities from the far east passed through the province and yielded a high customs revenue—the main motive for the annexation. The cities also profited from this trade and flourished greatly in the 2nd century, as their impressive surviving monuments show.

The emperor Diocletian divided Arabia into two provinces, a northern (to which he added the Palestinian regions Auranitis and Trachonitis) and a southern, with Bostra and Petra as their capitals. The southern province was united to Palestine by Constantine the Great. When it was detached again in 357–358 it was styled Palaestina Salutaris (or Tertia). Both provinces were governed by *praesides;* Justinian I promoted the *praeses* of Arabia to the higher rank of *moderator*. Their garrison commanders were styled *dux Arabiae* and *dux Palaestinae*. The churches show that the cities enjoyed a marked revival of prosperity in the 5th and 6th centuries and fell into decay only after the Arab conquest in 632–636.

ARABIAN ART: *see* ISLAMIC ART.

ARABIAN DESERT or EASTERN DESERT (AS SAHRĀ ASH SHARQĪYAH), of Egypt, 86,000 sq.mi. in area, extends from the Nile cliffs to the coral-reef coast of the Red sea. The much broken country culminates in a mountain range 4,000 ft. or more above sea level (Jabal Sha'ib, 7,150 ft.). The scanty population is based on wells and springs, especially in the valley of the Wadi Qina and around the administrative centre of Hurghada (Al Ghurdaqah). The desert was the source of some of the building stones of ancient Egypt (such as porphyry and granite). Phosphate is mined near Al Qusayr and petroleum is obtained from the area north of Hurghada. *See* also EGYPT; SAHARA. (R. W. SL.)

ARABIAN NIGHTS ENTERTAINMENTS: *see* THOUSAND AND ONE NIGHTS.

ARABIAN SEA (ancient MARE ERYTHRAEUM), the northwestern section of the Indian ocean, is bounded east by India, north by West Pakistan and southern Iran, and west by Arabia and the Horn of Africa. It has two important branches—the Gulf of Aden, connecting with the Red sea through the Strait of Bab-el-Mandeb; and the Gulf of Oman connected by the Hormuz strait leading to the Persian gulf. The sea, long a centre of coastwise sailing, forms part of the chief highway between Europe and India.

Over the greater part the Arabian sea is deep, exceeding 1,600 fathoms and there are no islands over the centre. Deep water reaches close to the bordering lands except in the northeast off the mouths of the Indus, Cutch, Kathiawar peninsula and the Gulf of Cambay. To the southeast, stretching for over 1,000 mi. from north to south, is the Maldive ridge, the highest parts of which are above sea level and form the Maldive and Laccadive Islands—very largely coral atolls. On the western side of the Arabian sea the Horn of Africa terminates in Cape Guardafui, 160 mi. to the east of which is the long plateau island of Socotra (British). Stretching southeastward from Socotra is the submarine Carlsberg ridge over which the water is less than 1,500 fathoms deep but drops to over 2,100 fathoms on either side. No boundary exists to demarcate the Arabian sea from the main part of the Indian ocean but this ridge may conveniently be used.

The Arabian sea lies in trade wind latitudes: from October to May the trade wind or northeast monsoon is blowing; from June to September it gives place to the strong southwest monsoon, and stormy seas result. (L. D. S.)

ARABIC LANGUAGE, one of the Semitic languages (*q.v.*), is spoken (1960s) by 100,000,000 people in a large area including the Arabian peninsula, the Fertile Crescent and north Africa. In addition, as the language of the Koran and the prayers of Islam it is important as a religious language throughout the Muslim world, and it has served as the vehicle of a vast literature (*see* ARABIC LITERATURE) extending from before the time of Mohammed up to the present day. It is customarily written in its own distinctive alphabet (*q.v.*), which has also spread with Islam and is used for writing several other languages of the Islamic world. Thus, in terms of the number of speakers and extent of its influence, Arabic is by far the most important Semitic language today and must be regarded as one of the important world languages.

As may be expected for a language used over such an expanse of space and time, Arabic shows tremendous variation, and the language of a pre-Islamic poem and the speech of a Cairo tradesman are quite dissimilar. On the whole, however, Arabic has been a conservative, slowly changing language, and the degree of difference, for example, between Arabic of the 8th and 20th centuries is clearly less than that between the English of the same periods. Two kinds of differences within Arabic are of special significance at the present time: the dichotomy between classical Arabic and the spoken dialects, and the differences among the various dialects themselves. The kind of Arabic which is used today for almost all written purposes and for certain formal kinds of speaking is substantially the Arabic of the Koran and the classical literature of the past; it is called classical Arabic (*al-lugha al-fuṣḥā* "the eloquent language"). The Arabic which is used in ordinary conversation by all speakers of Arabic, no matter how well educated, is quite different; it is often called colloquial Arabic (*al-lugha al-'āmmiyya*, "the popular language"). Although the classical is relatively uniform throughout the Arab world, showing only minor differences in vocabulary and syntax in different regions, the colloquial is split into various dialect areas with considerable divergence in sounds, grammar, and vocabulary. With the spread of literacy and increase in higher education in the Arab world the classical is becoming more and more widely known, and it is the hope of almost all Arab thinkers and leaders that eventually the common spoken language of Arabs will be either the classical or a middle language (*al-lugha al-wusṭā*), which pre-

serves the essential features of the classical with some changes introduced from the colloquial or elsewhere. This ideal is far from attained at the present time.

Phonology.—In structure Arabic is radically different from English and other well-known languages of Europe. Its sound system includes six "throat" consonants (*kh gh h ' ḥ '*) of particular difficulty for speakers of English and a series of "emphatic" consonants (*ṭ ḍ ṣ ẓ*) which influence strongly the pronunciation of the surrounding vowels. It has three short vowels and three long vowels (*a i u; ā ī ū*). Words always start with a single consonant followed by a vowel, long vowels are rarely followed by more than a single consonant, and there are never more than two consonants together.

The presence of certain consonants (especially the pharyngeals *ḥ* and '), the alternation of consonants and vowels, and the "emphatic" features of pronunciation give Arabic a highly characteristic sound which sets it apart from other languages.

Morphology.—The grammatical system of Arabic is based on the root-and-pattern structure typical of Semitic languages, which shows its fullest and most pervasive development in Arabic. The overwhelming majority of Arabic words have a stem which consists of two parts fitted together: the root, which is generally of three consonants and provides the basic lexical meaning of the word, and the pattern, which generally consists of vowels interlocked with the root consonants and gives the more specific grammatical meaning of the words. For example, the word *kātib* consists of the root *ktb* which has to do with writing and the pattern *-ā-i-* which identifies the active participle; the word *kātib* means approximately "one who writes," specifically often "a clerk." The full extent of this system becomes apparent from a listing of other words sharing either the root or the pattern.

ktb	*-ā-i-*
kitāb "book"	*shārib* "one who drinks"
'uktub "write!"	*'āmil* "one who does," "worker"
takātabū "they corresponded"	*sākin* "one who dwells," "inhabitant"
maktab "desk," "office"	*ṭālib* "one who begs," "beggar," "student"
kutub "books"	*khāliq* "one who creates," "Creator"
kuttāb "clerks"	*lāji'* "one who takes refuge," "refugee"
mukātib "correspondent"	*rākib* "one who rides," "passenger"
maktūb "letter"	*ṣāni'* "one who fashions," "craftsman"

In addition to the primary words the stems of which consist only of root plus pattern (*e.g., kātib, kitāb, 'uktub*) there are derivative words, the stems of which contain an additional element such as a doubling of the second root consonant (*sharrib*, "one who drinks to excess") or an infix *t* after the first root consonant (*'iftakara*, "he thought"). A pattern of this kind, which includes vowels and an additional element may be called a pattern complex, *e.g., ma--a* means the place where the action indicated by the root is carried out.

Classical Arabic also has a fairly small number of prefixes and suffixes, reduced still further in the dialects. These include prepositions (*bi-*, "at, by"), the definite article (*'al-*), subject markers of verbs (*e.g., ya-*, "he"; *-tum*, "you pl."), feminine and plural suffixes (*e.g., -at* fem., *-ūna* pl.), pronoun endings (*-hā*, "her") and, for classical only, case endings (*e.g., -u* nominative). The characteristic structure of an Arabic word is root + pattern (or pattern complex) + one or more affixes. A few words consist of prefix plus suffix with no stem at all (*bihā*, "by her"), and some others, chiefly particles, are not analyzable (*mā*, "what"; *sawfa*, sign of future; *yad*, "hand").

Compound words like English *bookcase, housekeeping* are almost nonexistent.

Conjugation.—The Arabic verb, which in many ways is the core of the grammatical system, has many derivational and inflexional forms, but the complexity is matched by the regularity and symmetry of the forms. Apart from several almost trivial exceptions, there are no irregular verbs in Arabic. For most primary verbs it is necessary to know only two forms to be able to predict all the rest, and for derivative verbs one form is usually sufficient. The complexity has been somewhat reduced in the dialects, but regularity and symmetry are still characteristic.

(Arabic Alphabet)

SIGN	NAME	EQUIVALENT	SIGN	NAME	EQUIVALENT
ا	alif	'(*)	ض	ḍād	ḍ
ب	bā	b	ط	ṭā	ṭ
ت	tā	t	ظ	ẓā	ẓ
ث	thā	th	ع	'ain	'(†)
ج	jīm	j	غ	ghain	gh
ح	ḥā	ḥ	ف	fā	f
خ	khā	kh	ق	qāf	q
د	dāl	d	ك	kāf	k
ذ	dhāl	dh	ل	lām	l
ر	rā	r	م	mīm	m
ز	zā	z	ن	nūn	n
س	sīn	s	ه	hā	h
ش	shīn	sh	و	wāw	w
ص	ṣād	ṣ	ى	yā	y

*A glottal stop when used as a sign of vowel length; represented by a macron when used as a sign of vowel length. † A pharyngeal sound.

Arabic verbs have two tenses: one, usually called the perfect, formed by the addition of suffixes; the other, usually called the imperfect, formed by the addition of prefixes and in several forms a suffix marking feminine or plural. The perfect generally refers to past time, the imperfect to present or future, but there are many uses in which this time difference is not so clear, and many scholars like to emphasize the aspectual nature of these two tenses. The same suffixes and prefixes are added to all verbs, whether primary or derivative. In classical Arabic the imperfect has three varieties differentiated chiefly by the final short vowel (indicative *-u*, subjunctive *-a*, jussive no ending). In the modern dialects, where the final short vowels have disappeared, this distinction is generally lost, but in some dialects it is continued in part by two forms of the imperfect, one with an added *b-* prefix (corresponding in usage to the classical indicative), the other without the *b-* (corresponding to the subjunctive and jussive). In addition to the two tenses there are imperative forms, active participle, passive participle, and verbal noun or *maṣdar*. In classical Arabic there are also some special forms called the "energetic," characterized by endings containing *n* added to certain jussive forms; these have disappeared completely in the dialects.

Arabic verbs are inflected for three persons, three numbers, and two genders. The first person, however, has no dual form and no gender differentiation. The modern dialects have all lost the dual forms, most sedentary dialects have lost the feminine forms of the second and third person plural forms, and in a few dialects the gender distinction in the second person singular of the perfect has disappeared. Otherwise the colloquial forms are analogous to the classical. A sample paradigm of the third person forms in classical and the Syrian dialect:

kataba	"he wrote"	*katab*
katabat	"she wrote"	*katbit*
katabā	"they (two) wrote"	*katabu*
katabatā	"they (two, fem.) wrote"	
katabū	"they wrote"	
katabna	"they (fem.) wrote"	

yaktubu	"he writes"	*byiktub*
taktubu	"she writes"	*btiktub*
yaktubāni	"they (two) write"	*byikitbu*
taktubāni	"they (two, fem.) write"	
yaktubūna	"they write"	
yaktubna	"they (fem.) write"	

The derivative verbs are traditionally listed in ten forms (plus several rare ones). All ten are never in use for the same root, but many roots have four or five derivative verbs in common use. The semantic value of each form may be indicated by terms like causative, reflexive, intensive, etc., but the precise meaning must be learned for each verb.

The traditional list follows—*f ʿ l* representing the first, second and third consonant of the root respectively (I is used for primary verbs).

II	*faʿʿala*	VI	*tafāʿala*	IX	*'ifʿalla*
III	*fāʿala*	VII	*'infaʿala*	X	*'istafʿala*
IV	*'afʿala*	VIII	*'iftaʿala*	XI	*'ifʿālla*
V	*tafaʿʿala*				

Most of these are alive in the modern dialects except that IV is rare or nonexistent everywhere; VII has been replaced by a form with initial *t-* in Maghrebi dialects and to some extent in Egypt; and IX and XI, which are equivalent in classical, have nowhere both been preserved.

Finally, the classical language has a passive which may be found with primary and derivative verbs (except IX and XI, and rare with VII). This is formed by the patterns: perfect *-u-i-a*, imperfect *u--a-;* thus *kutiba,* "it was written," imperfect *yuktabu.*

Declension.—The noun system of Arabic, in contrast to the complex, regular, highly predictable verb system, is relatively simple in number of inflexional forms but highly irregular and unpredictable. First, there is no difference in form, although there is in syntactical behaviour, between nouns and adjectives. Second, the number and gender of a given noun form are usually not clear from the form alone. Finally, for any given noun there is no way to predict whether it will have collective, singular and plural forms; or whether it will have one plural, several plurals, or no plural at all; or, if it has several plurals, whether they will have different meanings. All this is equally true of classical Arabic and the modern dialects.

Classical Arabic has in addition a declension system of three cases, called nominative, genitive, and accusative, which correspond in a limited way to the cases of these names in Latin. Duals and "sound" plurals have only two case forms, one for the nominative, the other for the genitive-accusative: nominative *-āni,* genitive-accusative *-ayni;* nominative *-ūna,* genitive-accusative *-īna;* nominative *-ātu(n)*, genitive-accusative *-āti(n)*. A handful of nouns have under certain circumstances long vowel case endings (*e.g.,* nominative *'abū-,* genitive *'abī-* accusative *'abā-* "father of"). All other noun forms, whether singular, collective, or plural follow a system which has short vowels as case endings (nominative *-u*, genitive *-i*, accusative *-a*) and an indefinite suffix *-n* which may be added after the case ending. Since some nouns take the indefinite *-n* and others do not, and since for various reasons, mostly connected with the presence of a semivowel as the final root consonant, some nouns have only a limited declension, there are actually six subtypes of declension. The declensional system is very simple compared to that of Latin, Russian, etc., but even this has disappeared completely in the modern dialects.

The pronouns of Arabic are outside the root-and-pattern system. The personal pronouns have two forms, independent and enclitic; the latter are added to nouns as possessives, and to verbs and prepositions as objects. Like the verb, the pronoun has forms for three persons, two genders and three numbers. The modern dialects have lost the same categories here as in the verb, but otherwise the forms are generally very similar to the classical. The third person pronoun forms in classical and Syrian are as follows:

Independent			Enclitic	
Classical	Syrian		Classical	Syrian
huwa	*huwwe*	"he"	*-hu*	*-o*
hiya	*hiyye*	"she"	*-hā*	*-ha*
humā	—	"they" (two)	*-humā*	—
hum	*humme*	"they"	*-hum*	*-hun*
hunna		"they" (fem.)	*-hunna*	

The demonstrative pronouns are quite varied in classical Arabic and have diverged greatly in the dialects.

ARABIC LITERATURE begins with the poems and proverbs of the northern Arabs of the late 5th to early 7th century A.D. The proverbs (of considerable linguistic and sociological interest) are recorded in several compilations made in the 8th century and after, of which the most celebrated is that of Maydani (d. 1124). Of written literature, before the redaction of the Koran in the 7th century, nothing is known.

PRE-ISLAMIC POETRY

The origins of Arabian poetry can only be guessed. Poets to whom the earliest pieces are attributed exhibit a fully developed art. Their poems are couched in elaborate metres, of which 16 were recognized when the metrical system was standardized in the 8th century by al-Khalil ibn Ahmad. What the original basis of this system was has given rise to many conflicting theories; for an exposition of the problem, with an ingenious new hypothesis, *see* G. Weil, *Grundriss und System der altarabischen Metren* (1958). In general, the system is quantitative, based on long and short syllables; to what extent ictus is an integral part of it, is disputed; the verse is divided into equally balanced halves, and the same rhyme is repeated at the end of each verse. The rule that every verse should form an organic whole gives a certain jerkiness to the poem, making it easy to displace lines and to extract pieces for inclusion in anthologies. The poetic language was that of the desert Arabs, somewhat standardized, and amplified by dialect variations. This became, under the influence of the Koran, the standard language of Arabic literature, and its richness led to the compilation of numerous commentaries and lexicons.

In form and content, the poems are of two kinds. On the one hand are the short occasional poems evoked principally by the emotions of war or revenge. Indeed, praise of his own tribe and abuse of its enemies were the functions of the ancient poet (*shāʿir,* literally "he who knows," an expression probably arising from the primitive feeling that poetic utterances were supernaturally inspired). Also important in this kind are elegies, for which a number of women poets, notably al-Khansa (*q.v.*), are famed. Distinct from this type of poems is the elaborate ode (*qasidah*) of from 60 to 100 lines. In this a regular scheme is followed whatever the subject. In the opening verses (the *nasib*) the poet depicts himself on a journey; he halts with his companions at a deserted camping ground, whose moldering traces recall an ancient passion, and tells of his love and the sorrow of parting; after this section he continues his journey and describes his horse or camel, comparing it to some wild animal of the desert. The natural descriptions or accounts of the chase thus introduced

are often the most attractive part of the poem. This leads to the occasion of the poem, which may be praise of his tribe or of his own gallantry, descriptions of camp or desert life or, most frequently, panegyric of some patron.

Transmission.—The oral transmission of these compositions over a period of 150 to 250 years or even longer was by a class of professional reciters (*rawi*), among whom many of the most famous poets were numbered. The *rawis* certainly possessed remarkable powers of memory, but it must be allowed that the poems thus preserved were liable to mutilations, omissions and transpositions. The divergences in the texts of many ancient poems are great, and often portions of different poems are found pieced together. Unfortunately several of the most famous *rawis*, especially two of those who first undertook the writing down of the early poems in the 8th century, Hammad al-Rawiyah (*q.v.*) and Khalaf al-Ahmar, are suspected of dealing arbitrarily with their material and have been declared to be clever forgers. Thus, whenever any particular verse is attributed to a pre-Islamic author, it is necessary to consider to what extent it can be regarded as authentic. Few modern scholars, however, would agree wholly with the revolutionary views propounded by D. S. Margoliouth (in *Journal of the Royal Asiatic Society*, 1925) and Taha Husayn (in *Fi al-Shi'r al-jahili*, 1926), according to whom the entire canon of "pre-Islamic" poetry is a forgery of early Islamic date. Margoliouth's views were ably refuted by E. Bräunlich in *Orientalistische Literaturzeitung* (1926); and the modern view more or less coincides with the summing-up of the authenticity problem in relation to the seven *Mu'allaqat* by A. J. Arberry in *The Seven Odes* (Allen & Unwin Ltd., 1957, p. 253): "The weight of evidence is heavily in favour of the Seven Odes being genuine products of the age to which Arab tradition has assigned them. But this is not to say that the form in which we have received them is their original form."

Collected Poems.—The poems attributed to the early bards have survived in two kinds of collection. There are the *diwans*, or collected poetical works, of the principal poets; *e.g.*, of Imru'-al-Qays, Zuhair, al-Nabighah, A'sha, Tarafah, Hassan ibn Thabit (*qq.v.*). There is one tribal *diwan* (of the Hudhayl tribe); and there are many poets of whom only a few pieces survive; *e.g.*, the robber poets Ta'abbata Sharran and Shanfara, the Christian poet 'Adi ibn Zayd, the Jew Samaw'al ibn 'Adiya and the religious poet Umayyah ibn Abi-al-Salt.

The second category consists of anthologies, of which the most famous are the *Mu'allaqat* (*q.v.*), the name given to a group of seven pre-Islamic poems, which represent almost every type of ancient Arabian poetry in its excellences and its weaknesses; the *Hamasah* (*q.v.*), compiled by Abu Tammam (*q.v.*) *c.* 836 A.D.; and the *Mufaddaliyat* (*q.v.*), an anthology in which almost all the poets represented belong to the pre-Islamic age.

In addition to the anthologies, various other works contain poetical citations of value: above all the *Kitab al-Aghani* ("Book of Songs") of Abu-al-Faraj al-Isfahani (*q.v.*). The *Kitab al-shi'r wa' l-Shu'ara* ("Book of Poetry and Poets") of Ibn Qutaybah (*q.v.*) and the *'Iqd al-Farid* of Ibn 'Abd Rabbihi (*q.v.*) are also noteworthy. (C. J. L.; TH. N.; H. A. R. G.; X.)

POST-ISLAMIC POETRY

Umayyad Period.—During the 1st century after Mohammed there was little change in the character of Arabic poetry. The four outstanding poets were al-Akhtal (*q.v.*), al-Farazdaq (*q.v.*), Jarir ibn 'Atiyah al-Khatfi (*q.v.*) and Dhu al-Rummah. In the work of the last it is obvious that the *qasidah* is becoming a stereotyped and academic exercise. Poets still carried on the traditions of tribal panegyric and satire but the new conditions of city life, both in the conquered lands and in the metropolitan cities of Arabia, brought about a change in Arab manners and pursuits which led to the rise of new modes in poetry. The love lyric was established as an independent form by Omar ibn Abi Rabi'ah of Mecca and his fellow-countryman Jamil, and a sort of Platonic love became the theme of several poetic romances associated with the tribe of 'Udhrah, and attributed to a number of poets, of whom the most famous are Majnun Bani 'Amir and Layla. The poems of the caliphs Yazid I (680–683) and Walid II (743–744) were the precursors of the wine songs and hunting poems of the next period. An attempt to remodel the *qasidah* in the freest of Arabic metres, the *rajaz* (with an iambic-type rhythm), was made by 'Ajjaj and his son Ru'bah. Although this tendency was not developed, the *rajaz* metre was retained for impromptus (as in the pre-Islamic period) and for long descriptive poems.

Abbasid Period.—The Persian atmosphere of the Baghdad court after the establishment of the Abbasid caliphs in 750 strongly favoured these new tendencies, which reached their apogee in Abu Nuwas (*q.v.*) and his brilliant contemporaries. Thenceforward Arabic poetry flowed in a number of channels. The traditionalists continued to imitate in their ceremonial odes the subjects, mannerisms and metres of the old desert poetry, save for the introduction of rhetorical tropes (*badi'*) in place of the pictorial imagery of the ancient poets. This fashion was set by Muslim ibn Walid (d. 803), followed by Abu Tammam (*q.v.*), and carried to the verge of excess by al-Mutanabbi (*q.v.*). On the other hand the school of Abu Nuwas used metres with much more variety and excelled in anacreontic and occasional verse. Even for this later period the text or authenticity of many poems is uncertain. Generally speaking, the poets sought less after depth and originality than elegance in expression and brilliance of metaphor, and the polished and delicate productions of later writers such as Baha al-Din Zuhair (*d.* 1258, *q.v.*) recall English 17th-century and Augustan verse. Nevertheless some struck out new paths: Abu-al-'Atahiyah (*q.v.*), whose moralizing verse is expressed in unaffected popular language; Bashshar (d. 783), chiefly celebrated as an erotic poet, who employed a Wordsworthian simplicity of language; Ibn al-Mu'tazz (d. 908), the author of a long historical poem and of other brilliant and original verse; Abu-al-'Ala al-Ma'arri (*q.v.*), in whose *Luzumiyyat* Arabic poetry touches its deepest human note; and the mystical poets Ibn al-'Arabi and Ibn al-Farid (*q.v.*).

Western Poetry.—In Spain and the west, Arabic poetry at first continued along traditional lines, represented by Ibn Hani' (d. 983) of Seville. Later, Ibn Rashiq (d. 1070) of Kairouan, Ibn Zaydun (d. 1071) of Cordoba, Mu'tamid king of Seville (d. 1095) and his vizier Ibn 'Ammar (d. 1078), with whom was associated the most famous of the Arab poets of Sicily, Ibn Hamdis (d. 1132), were the principal among a galaxy of poets who released themselves from the old conventions and used their verse for self-expression. A still greater breach with tradition was the rise of strophic verse, which conservative influences had hitherto succeeded in repressing in the east. This new verse-form is marked by internal rhymes with a rhyming refrain to mark the end of each strophe, and makes its appearance in the *muwashshah* (*q.v.*, in literary language) and the *zajal* (in colloquial Arabic), which was raised to literary rank by the troubadour Ibn Quzman (d. 1160). These productions, which are nearly all erotic, exercised a strong influence on nascent Provençal poetry and also, reaching Egypt at the end of the 12th century, took root there. The Spanish-Arabic *muwashshah* has the curious feature of concluding with a couplet written in one of the early Romance dialects of the peninsula.

There are numerous anthologies of later poetry. Some were devoted to special genres; *e.g.*, wine songs. Among those of more general scope mention should be made of the *Yatimat al-dahr* of Tha'alibi (d. 1038); the *Khizanat al-adab* of 'Abd al-Qadir al-Baghdadi (d. 1682); and two anthologies of Spanish-Arabic verse, the *Qala'id al-'iqyan* by al-Fath ibn Khaqan (d. 1134), and the *Rayat al-mubarrizin* by Ibn Sa'id al-Andalusi (d. 1274), translated in A. J. Arberry's *Moorish Poetry* (1953).

From the 13th century until the rise of the modernistic movement in the 19th century (*see* below) Arabic literature fell into a period of decadence in which most works were imitative. (H. A. R. G.; X.)

BELLES-LETTRES

The most striking and characteristic feature of Arabic literary prose is the style known as *saj'* or "rhymed prose." This typically consists of a succession of pairs (occasionally triplets or more) of short rhyming expressions. There is a rhetorical and antithetical

balance of sense between the pairs, and they are expressed with a certain loose rhythmical balance not bound by strict metre. There is no doubt that the formal oration (*khutbah*) cast in this style is of great antiquity, and in pre-Islamic tribal society the orator (*khatib*) was a figure whose importance was nearly comparable with that of the poet. In the earliest times of Islam, in spite of a tendency to frown on poetry and *saj'*, the Koran itself was partly drafted in a form of rhymed prose, while the *khutbah*, turned to religious and homiletic uses, became an integral part of the Friday religious ceremonial and was employed on numerous other occasions. One of the most famous later exponents of the *khutbah* style was Ibn Nubatah al-Fariqi (d. 985). Such was the dominance of the *saj'* tradition that it affected much Arabic prose, giving it a tendency to a rhetorical and antithetical style reminiscent of 17th- and 18th-century English sermons, even when strict *saj'* is not being employed.

The beginnings of Arabic literary prose fall in the latter days of the Umayyad caliphate, the chief pioneers being 'Abd al-Hamid al-Katib (d. 750) and Ibn al-Muqaffa' (d. 760). The works of both exhibit a mingling of the *khutbah* style and a more sophisticated and fluent style which may derive from the literary traditions of Sasanian Persia. The most celebrated work of Ibn al-Muqaffa', *Kalila wa Dimna*, is a translation from a Pahlavi (middle Persian) version of the Indian book of animal fables, the *Panchatantra*. (*See* BIDPAI, FABLES OF.)

The following three centuries are the golden age of Arabic prose, studded with the names of brilliant writers, such as the essayists al-Jahiz (*q.v.*) and Abu Hayyan al-Tawhidi (d. *c.* 1000), and the critic Ibn Qutaybah (*q.v.*). Here, too, we encounter Abu-al-'Ala al-Ma'arri (*q.v.*) with his letters in formal *saj'* and his brilliantly original fantasy the *Risalat al-Ghufran*, which pictures a visit to the other world. These writers forged out of Arabic a prose diction which for subtlety and expressiveness is not easily paralleled.

Anecdotal writings occupy a special place in Arabic prose literature. The Arabs were an avid audience for moral, instructive or amusing anecdotes, and this gave rise to a number of compilations under classified headings. The outstanding name is Tanukhi (d. 994), who was responsible for three such compilations: the partly extant *Nishwar al-muhadarah* (Eng. trans. by D. S. Margoliouth, *The Table Talk of a Mesopotamian Judge*, 1922, and in *Islamic Culture*, vol. 3–6, 1929–32); the *Mustajad*, anecdotes of generosity; and above all the immensely popular *Faraj ba'd al-shiddah* ("Deliverance After Anguish"), later translated into Persian.

Works of this kind led to a new literary form, the *Maqamat* ("Assemblies"). Al-Hamadhani (d. 1007, *q.v.*) is credited with initiating it. Previous anecdotal literature had at least purported to be factual. Hamadhani's *Maqamat* make no pretence of being so; they are a collection of short stories, mainly picaresque, woven round the names of two fictitious protagonists. The genre was developed and standardized a century later by al-Hariri (*q.v.*), and although numerous later authors followed him, none achieved the lasting fame of his *Maqamat*.

The popular romances and story-cycles of the type of the *Thousand and One Nights* (*q.v.*) were early in vogue. But such tales, the stock-in-trade of professional storytellers, were beneath the notice of an educated man. Ibn al-Nadim in his bibliographical *al-Fihrist* (composed 988) characterizes the *Thousand and One Nights* as a "worthless and silly book." The only serious author to concern himself with such tales is Jahshiyari (d. 942), who collected a large number from storytellers as well as from manuscripts. (For further specimens of this genre *see* SINDBAD THE SAILOR; LUQMAN; and a collection edited by H. Wehr, *Das Buch der wunderbaren Erzählungen*, 1956.) (A. F. L. B.)

HISTORY AND BIOGRAPHY

Early Forms.—Before Islam, history, like other types of prose literature, was virtually unknown, although tribal stories and genealogies—often embellished by legend—were transmitted orally. In the 2nd century of Islam—the 8th–9th century A.D.—oral transmission was systematized in the science of Hadith (*q.v.*)—the system of tradition—and statements were not considered authoritative unless they were supported by a chain of authorities (*isnad*). This method was applied to other sciences, including history. Thus, the earlier histories are encumbered by these *isnads*, which had to precede each major statement of fact. Normally, the historian did not synthesize or generalize—Ibn Khaldun (*q.v.*) being a notable exception—he used his critical judgment in selecting facts only by checking *isnads*. Another feature of Arabic history was the relating of events in strict chronological order (the Arabic word for history, *ta'rikh*, means "to date") so narratives tended to be disjointed. In shorter biographies, year-by-year chronicling was often abandoned, and the use of *isnads* was mitigated according to the writer's taste. Later historians and biographers largely abandoned the *isnad* in favour of the verbatim quoting of earlier writers.

In the 1st century of Islam, preoccupation with religion and wars impeded the writing of history, though they made it all the more necessary. With the widening frontiers of the Islamic state, the dispersion of the Arabs and the increasing complexity of life and government, oral traditions had to be written down, if they were to survive in reliable form. An early life of the Prophet by Ibn 'Uqba (d. 758) has survived only in fragments. The oldest extant history is the life of the Prophet by Ibn Ishaq (*q.v.*), but this is only available in the revision by Ibn Hisham (*q.v.*). It is considered generally reliable, despite some admixture of fables and the inclusion of spurious early poetry. Al-Waqidi (*q.v.*) wrote a book about the Prophet's campaigns more detailed than Ibn Ishaq's work, and Ibn Sa'd (*q.v.*) wrote biographies of the Prophet and his companions. During this early period, historians, like other writers, preferred the short, specific monograph to the general work. Among authors of these, besides al-Waqidi, were Abu Mikhnaf (d. 748), al-Mada'ini (d. 840), Abu Ubaydah (d. 825), and al-Azraqi (d. *c.* 858), whose history of Mecca was the precursor of numerous local histories.

General Histories.—From the 9th century A.D., the general history became popular. Ya'qubi (*q.v.*) wrote a general history of value, and al-Baladhuri (*q.v.*) wrote an account of Arab conquests and a large genealogical history of the Arabs. Al-Tabari (*q.v.*) was the first general historian of genius; and some still consider his *Annals* the finest history written in Arabic. It was freely drawn on by later historians; it was abridged and completed and it was translated (in part) into Persian by Bal'ami in 963, thus providing a pioneer work of Persian prose. Modern readers may find Tabari's year-by-year arrangement and his use of the *isnad* tiresome. Yet the *Annals* are of vital importance. Moreover, they do treat the more important events at greater length. Among later historians to draw freely on Tabari was Ibn Miskawayh (or Miskawayh) (d. 1030). His *Tajarib al-Umam*, containing the history of the kings of ancient Persia, and that of the Arabs up to his time, is highly praised by D. S. Margoliouth and Bernard Carra de Vaux (see *Bibliography*). Miskawayh is outspoken, reasonably impartial and skeptical of the supernatural. He includes vivid detail, and depicts exciting scenes which remain in the mind. He throws much light on political, administrative and economic matters. Ibn al-Athir (*q.v.*) abridged and completed Tabari's work in his *Kamil* ("Complete"). It contains important information about the western Islamic world—Sicily, North Africa and Spain. Mention must also be made of the autobiography of 'Usama ibn Munqidh (Eng. trans. by G. R. Potter, *The Autobiography of Ousama*, 1929) which shed much light on Saladin and his times.

Later Works.—The number of historical and biographical compilations in the later centuries is enormous. The most important writers—al-Masudi, al-Biruni, Abu 'l-Faraj (*see* BAR-HEBRAEUS), Ibn Khaldun, al-Suyuti, and Hajji Khalifa (*see* KATIB CHELEBI)—are the subjects of special articles. Several works by other authors deserve mention. The *Kitab al- Wuzara'* ("Book of Wazirs") of Hilal al-Sabi' (d. 1056) is a mine of information about the social life of the 9th and 10th centuries. The history of Mohammed al-Ghaznawi (*Kitab al-Yamini*) by al-'Utbi (d. 1036) set the fashion for the rhetorical style in history-writing. 'Imad al-Din (d. 1201) followed it in his histories of Saladin and of the Seljuk dynasties,

and Ibn 'Arabshah (d. 1450) carried it to excess in his history of Timur (Tamerlane).

During this period many local histories were written. These were usually either bare chronicles of events, or panegyrics of local dynasties. An exception is the excellent history of Egypt by 'Abd al-Latif (d. 1231), but many so-called local histories degenerated into collected biographies of the citizens of the provinces or towns with which they dealt. Two monumental works of scholarship belong to this category—the history of Baghdad by al-Khatib al-Baghdadi (d. 1071), and the history of Damascus by Ibn 'Asakir (d. 1176).

Besides those devoted to particular localities, there are collected biographies of a general nature, and also those dealing with men of learning. In the first category, the biographical dictionary of Ibn Khallikan (*q.v.*) stands out. The *Mu'jam al-Udaba* ("Dictionary of Learned Men") compiled by Yaqut is the leading example of the second category. Ibn Khallikan's work was expanded, completed, or brought up to date by several authors, notably by al-Safadi (d. 1363) in his *Wafi bi 'l-Wafayat* and by Ibn Shakir al-Kutubi (d. 1363) in his *Fawat al Wafayat*. Ibn Abi-Usaybiah (d. 1270) wrote a history of physicians and there were collected biographies of lexicographers, grammarians, theologians, Koranic readers, *sufis*, etc. Such books, when not arranged alphabetically, were often termed *Tabaqat* ("categories"), since they grouped the subjects of their biographies according to geographical location, generations, or schools of ideas and methods. It was a form in which the Arabs excelled. These works are useful, not only for the technical information which they contain, but also for the vivid pictures they paint of the life of the people. Characters are sketched by interesting anecdotes, which often display a strong sense of humour.

The 14th and 15th centuries were remarkable for the appearance of encyclopaedic compendiums, intended as handbooks for the official classes. The two earliest were the encyclopaedia of al-Nuwari (d. 1332) and the *Masalik al-Absar* by Ibn Fadlallah (d. 1348). Later came the *Subh al-A'sha* of al-Qalqashandi (d. 1418). Meanwhile there were last flickers of the flame of history-writing before Arabic literature suffered almost total eclipse under the Ottoman Turks. Al-Maqrizi (d. 1442) wrote a history of Egypt, a history of the Mamelukes, and an enormous biographical dictionary of Egyptian princes and notables. A worthy conclusion to the long sequence of great histories was provided by the history of Muslim Spain by al-Maqqari (d. 1632).

Historical Romances.—From the earliest days of Islam, love of the marvelous and veneration of the Prophet gave rise to fables about him which found their way into serious histories. Later, there were legends about the wars of conquest, and about Ali and his family. So there sprang up a romantic tradition, with a popular literature of its own. In the oldest specimens, such as the story by Ibn 'Abd al-Hakam (d. 871) of the conquest of Egypt and North Africa, truth and falsehood are mixed. Most extant literature of this kind is, in its present form, much more recent; *e.g.*, the story of the death of Husain by the pseudo-Abu Mikhnaf, and of the conquest of Syria by Waqidi. Later, such books were often treated as authentic, and material from them found its way into accepted history.

On the other hand, there was a class of popular romance which was never taken for serious history. The best-known examples are the story of 'Antar (Antara), a romance of Arab desert life, and the story of the Bani Hilal, one of the Arab tribes which occupied the Libyan desert in the 11th century. These stories are still retailed in school textbooks, and by village storytellers, in the middle east.

TECHNICAL AND SCIENTIFIC LITERATURE

Geography and Travel.—Arabic geographical literature was stimulated in the first place by Greek mathematical geography and the necessities of administration. The first roadbook was written in the 9th century by Ibn Khurdadhbih, the royal postmaster at Samarra. Soon afterward love of travel and intellectual curiosity produced a valuable series of descriptive works of which those of Ya'qubi (*q.v.*), Ibn Haukal, al-Masudi (*q.v.*) and Makdisi (Muqaddasi) are the most famous. While these early writers prided themselves that their knowledge was derived from personal investigations, their successors, Idrisi, Abulfeda (*qq.v.*), Yakut and Bakri, contrived to compile excellent geographical treatises based almost entirely on written and narrative sources. There are also accounts of embassies and journeys both into central Europe and the remoter parts of Asia. Ibn Jubayr wrote an admirable journal of his travels to and from Mecca by way of Syria and Egypt in 1181–84. In the 14th century Ibn Batutah (*q.v.*) earned the title of "The Traveler of the Arabs" by his extensive journeys. The commercial relations long existing between the Persian gulf and India and the far east produced several exceedingly interesting works on those countries, notably the *Kitab 'Adja' ib al-Hind* (*Marvels of India*) by Bozorg ibn Shahriyar, besides manuals of navigation in prose and verse. In the 10th century some Spanish-Arab sailors even set out from Lisbon to cross the Atlantic. In later times geography shared the general decline, and, except for the geographical sections of the great encyclopaedias mentioned above, was merged into cosmography. The works of the earlier cosmographers, Qazwini (d. 1283) and Dimashqi (d. 1327), are not without interest and importance, but with the economic ruin of the Arabic world all study of geography ceased. (*See* also GEOGRAPHY.)

Philology.—The systematic study of Arabic grammar began in Iraq, as an aid to the study of the Koran, probably even in the 7th century, and it was fully established by the end of the 8th century. Ancient Arabic poetry, previously transmitted orally, was collected and recorded to help the understanding of the language. Rival grammatical schools were set up at Basra and Kufa. The Kufans set less store by analogy than the Basrans. Later, scholars gravitated to Baghdad. Sibawayh (*q.v.*) of Basra wrote the first full-scale grammar, and other members of the school were Abu 'Ubaydah, al-Asma'i (*q.v.*), and Ibn Duraid (*q.v.*). The first dictionary was compiled by Khalil (*q.v.*) at the end of the 8th century, and a whole series followed, notably those of Ibn Duraid, Jauhari and Ibn Faris (10th century).

The great dictionaries, still in use, date from a later period. They are the *Lisan al-'Arab* by Ibn Manzur (d. 1311) (new edition with introduction by Ahmad Faris, 15 vol., 1955–56); the shorter *Qamus* of al-Firuzabadi (d. 1414); and the late commentary on the latter, the *Taj al-'Arus*, by Murtada al-Zabidi (d. 1790), on which Edward Lane (*q.v.*) based his lexicon.

Philosophy and Science.—Arabic philosophical and scientific studies are dealt with elsewhere (*see* ARABIC PHILOSOPHY; ASTRONOMY; CHEMISTRY: *History of Chemistry;* MATHEMATICS, HISTORY OF, etc.). All such studies came to the Arabs through Syriac translations from Greek, supplemented by Indian and possibly Persian influences, and were confined to comparatively small circles of students. (J. A. HD.)

MODERN LITERATURE

While the writing of books and composition of poetry continued in Egypt and Syria, and sporadically elsewhere, throughout the 17th and 18th centuries, little of originality or value was produced. During the 19th century the new political, social, economic and intellectual movements resulting from contact with Europe prepared the way for a revival of Arabic letters, particularly in Syria and Egypt. This took on the one hand the form of a throwback to classical Arabic models, represented in Syria by Nasif Yaziji (1800–71), the author of *Maqamat* on the model of al-Hariri, and in Egypt by the activities of the orthodox theological seminary of al-Azhar. On the other hand the influences exerted by the missionary schools in Lebanon, and the western sympathies of Mohammed Ali and Ismail (*qq.v.*), khedives of Egypt, led to a rapid and superficial assimilation of western ideas, fostered by the translation of large numbers of French works, especially scientific works, novels and plays. The westernizing movement was strengthened by the creation, in the last decades of the century, of an Arabic daily press which contributed to the evolution of a new and more flexible literary style, and also of an Arabic theatre. In Egypt a movement to reconcile the two schools, classical and modernist, was initiated by Shaykh Mohammed 'Abduh (d. 1905),

but it broke up after his death into a conservative and a modernist wing. The latter crystallized out in Egypt after 1920 in the essays, novels and descriptive works of a remarkable group of writers (*see* C. C. Adams, *Islam and Modernism in Egypt*, 1933), followed in other Arab countries with varying degrees of success. In the first quarter of the century a more radical reorientation was attempted by a number of Syro-American writers of Lebanese origin in the United States and Brazil, but it died out with the generation that produced it, and had little influence except in Lebanon. After the outbreak of World War II, the Egyptian movement also lost much of its impetus, and was succeeded by a period of psychological reaction, offset by some tentative experiments. Throughout this period Taha Husayn and al-'Aqqad in Egypt remained sobering influences in all fields of Arabic literature. The improvements in education and communications following World War II coupled with the rise of Arab nationalism led to a greater diffusion of Arab literary movements throughout the middle east and North Africa. Arabic poetry in particular began to free itself from the conventions of Ahmad Shauqi (*q.v.*) and Hafiz Ibrahim (d. 1932) and to emerge as the main outlet for the new political consciousness. (H. A. R. G.; A. EL-T.)

ARABIC PHILOSOPHY. Medieval Arabic philosophy represents a case of the adaptation of Greek philosophy to a different civilization and to a new language. Latin translations of Hellenistic philosophy in Cicero's day and of Neoplatonic thought by Christians (such as Marius Victorinus and Boethius) in the 4th and 5th centuries and the philosophical works in Latin based on these translations are both of a different character from it. The Jewish philosopher Philo of Alexandria (1st century A.D.) and, following his lead, the Greek Fathers of the Christian church (from Clement of Alexandria to Gregory of Nyssa and beyond) had made successful attempts to give Greek philosophy, divorced from its roots in Greek religion, a place within a world dominated by new and fundamentally different religious attitudes of the Hebraic type; there was no linguistic difficulty involved in this. The syllabus of learning thus established in the Greek church was adopted by the different Syriac churches, and hence there are Syriac versions of Greek philosophical texts from the middle of the 5th century A.D. down to the 5th century of the Muslim era. But Islam as a religion is different from Judaism and from Christianity, although likewise based (unlike the Greek way of life) on divine revelation and on a holy book; and Arabic proved to be a very suitable medium for expressing Greek thought, more adaptable to it than Syriac (although the precedent of previous translations into a Semitic language facilitated the rapid growth of an abstract Arabic language and terminology). It goes without saying that, apart from these fundamental factors, special historical circumstances and special trends in the development of Islam influenced the destinies of Islamic philosophy and the work of individual Muslim thinkers. Since Islam is a universal religion, it is not surprising that most of the outstanding philosophers of the Arabs, like many of their other famous writers, were not of Arabian descent (al-Farabi, for instance, was a Turk, Rhazes and Avicenna were Persians).

THE TRANSLATORS

Since medieval Arabic philosophy is wholly dependent on the Greek texts which reached the world of Islam, we cannot afford to neglect the work of the translators, who, from the second half of the 8th century onward, provided the philosophers who could read neither Greek nor Syriac with the Greek scientific view of the world and with Greek natural theology. These translators were, with very few exceptions, Nestorian, Jacobite and Melchite Christians and translated sometimes directly from the Greek and sometimes from intermediate Syriac translations (the only Latin author ever translated into Arabic in the middle ages was the Christian historian Orosius). Greek manuscripts were still to be found in the cities of Mesopotamia, of Syria, of Palestine and of Egypt in the 9th century A.D., when the eminent translator Hunain ibn Ishaq was working; we know of the study of Greek texts of Galen in Baghdad at the same time and have good reason to believe that Greek was still spoken there at the end of the 10th century. The activity of the translators continued, in varying intensity, until the 11th century, the main groups being (1) the "old" translators, who worked in the days of the Mu'tazilite caliphs al-Ma'mun (813–833) and al-Mu'tasim (833–842); (2) Hunain ibn Ishaq (called Johannitius by the scholastics; d. 873) and his numerous pupils in Baghdad; and (3) the Baghdad school of the 10th and 11th centuries, who seem to have translated exclusively from the Syriac. They succeeded in establishing a continuous teaching of Greek philosophy in the capital of the Abbasid caliphate. The "old" translations are not entirely superseded by the more recent ones, and we find them still being used much later; *e.g.*, in Averroes' exegesis of Aristotle. The growth of an abstract Arabic style is mainly due to these versions of Greek philosophy, and we can follow its gradual improvement in the works of the Islamic philosophers who used them for their own purposes. Very few Greek loanwords are eventually preserved (for instance *hayula* from *hyle*; *ustuqus* from *stoicheion*). It was not always possible to reproduce the subtle distinctions of the refined philosophical terminology of the Neoplatonists and the late commentators on classical Greek philosophy with equivalent Arabic terms; but, on the other hand, the Arabs could sometimes use various words for an ambiguous Greek term. They even coined new abstract terms, some of which found their way into medieval Latin: *mahiyya-quidditas*, "quiddity," for instance, is still in use, as also is *qabliyya-prioritas*, "priority." Some pairs of correlative concepts can be expressed in Arabic more adequately than in Greek, by using the same root. There are a few changes for religious reasons, such as the frequent substitution of the singular (*allah* or *ilah*) or of "angels" (*mala'ika*) for the Greek plural "gods" (*theoi*), which makes it easier to accept the cosmology and astronomy with its stellar gods who are common to most late Greek philosophers. A Greek-Arabic glossary of philosophical terms from the translations would greatly assist the study of Arabic philosophical texts.

The works thus made available to Arabic thinkers were those which were still being read and studied in the Greek philosophical schools during the 6th century, as follows: (1) Plato and Aristotle and their commentators; (2) philosophical works by Galen and a few Middle-Platonic authors (*see* ACADEMY, GREEK); and (3) books by Neoplatonists and other later writers. Arabic thinkers knew most of the major lecture courses of Aristotle except the *Politics* (upon which no ancient Greek commentary seems ever to have been written) and studied them with the help of commentaries by Nicolaus Damascenus (1st century A.D.), Alexander of Aphrodisias (early 3rd century), Porphyry (late 3rd century), Themistius (4th century), Simplicius and John Philoponus (both 6th century) and others. Of the original philosophical writings of Alexander, they possessed more than have survived in the Greek. There were also texts with marginal notes, and abridgments of original works in the form of summaries and paraphrases. The whole of Plato seems to have been known in some form, but translations of the complete *Timaeus*, *Republic*, *Laws* and *Phaedo* are particularly conspicuous. The main interpreters of Plato who were followed were Middle Platonists and the Neoplatonist Proclus (5th century). Other works known were the *Placita philosophorum* included in the writings of Plutarch and a paraphrase of Plotinus, known as the *Theology of Aristotle*, but Plotinian ideas also reached the Arabs in other ways. It would be premature to give a com-

plete list of all the works translated, but three writings deserve mention: the first two are the *De aeternitate mundi* of Proclus and the reply to this by John Philoponus, in which the former defended the eternity of the world, appealing to the authority of Plato and Aristotle, whereas the latter argued in favour of a real beginning and end of the world and was prepared to accuse the great philosophers of error; the third is a similar work exclusively against Aristotle. These writings proved important for later discussions between various groups of Arabic philosophers; so, too, was the *De causis* (a rearranged extract from Proclus' *Elements of Theology*) for its impact on Latin medieval thought. The number of Greek philosophical texts known in Latin versions before the days of the schoolmen in the later middle ages was only a very small fraction of those known to the Islamic world.

By the middle of the 20th century only a relatively small number of the Arabic translations known to have been made had actually been traced and published, but new material was constantly turning up in western and, particularly, in eastern libraries. As some Greek philosophical texts which had still been available when Muslims became interested in Greek thought were lost during the subsequent centuries of Byzantine history and are preserved only in Arabic versions or reflected in Arabic philosophical works, these versions, apart from their usefulness to the student of Arabic philosophy, can help to increase our knowledge of Greek literature, not only in the philosophical field, but also in those of science, of medicine and of mathematics. Three of Galen's works may be cited in this respect: his treatise on moral philosophy, *Peri ethon;* his paraphrase of Plato's *Timaeus;* and his treatise *On Medical Experience,* which contributes to the history of Greek skepticism. Another example is the pseudo-Aristotelian *Peri phyton* (by Nicolaus Damascenus); and the case of Alexander of Aphrodisias has already been mentioned. Themistius' commentaries on the *De caelo* and on the *Metaphysics* are preserved only in a Hebrew version of an Arabic translation.

THE PHILOSOPHICAL SYLLABUS

Medieval Arabic philosophy is almost entirely based on the late Greek syllabus of learning. All the philosophers were eager to naturalize it in the Islamic world; there is no striking difference in this respect between al-Kindi's *Introduction to the Study of Aristotle,* al-Farabi's *De divisione scientiarum* (extensively used by Dominicus Gundisalvi), Avicenna's encyclopaedias of philosophy (well known in the west, at least from 1200 onward) and Averroes' expositions of Aristotle's various treatises (which helped the west for centuries in the understanding of Aristotle), though these authors flourished each in a different century, from the 9th to the 12th.

While they all—with the exception of the Platonist Rhazes and his like—considered Aristotle as the greatest philosopher, they yet believed, with Porphyry and others, though in varying degrees, in the substantial identity of Plato's and Aristotle's views; and their view of Aristotle was, again in different ways, generally coloured by Neoplatonism. This attitude applies to metaphysics, to ethics and to psychology in particular but can be noticed in other fields of philosophy as well.

This philosophical syllabus was commonly accepted as a treasure house of truth discovered by the ancients, and the new tradition followed the static system established in the late Neoplatonic schools. It comprised mathematics (based on the reading of Euclid as a primer), astronomy (based on Ptolemy's *Almagest*), logic (based on Porphyry's *Isagoge* and on Aristotle), the natural sciences and psychology (based on Aristotle), metaphysics (based on Aristotle and on Neoplatonic books), ethics (based on Platonizing treatises and on Aristotle) and politics (based, if studied at all by Arabic thinkers, on Plato's *Republic*). It is needless to emphasize again that the late Greek commentators were considered the appropriate guides to the understanding of the classical texts and that there was no attempt at a completely fresh and original approach. There were no organized or properly endowed schools of philosophy such as had existed in the Greek world since the days of Plato and Aristotle, nor was there anything comparable to the medieval universities of Paris or Oxford; but there is a continuous tradition of philosophical reading from the 9th century, which spread over the whole Islamic world, from Bukhara, the home country of the Persian Avicenna, to Spain and to Morocco, where Averroes composed his philosophical works.

It is important to be aware of these peculiar conditions in order to understand the history of Islamic philosophy, which is by no means uniform or repetitive. Its variety depends, especially in the early stages, on the various trends of ancient thought with which each philosopher became acquainted and on the material which each selected in accordance with his personal predilections and particular gifts. They all were concerned to give philosophy a permanent and decisive position in an environment which was utterly different from that in which Greek philosophy had grown and existed for more than 1,000 years. They attempted this naturalization in various ways, seeking to establish that philosophy could provide the best answer to the basic problems of Islamic life; in the long run, however, they did not succeed in this endeavour. Al-Ghazzali's efficient and determined attack on them in *The Incoherence of the Philosophers* (*c.* A.D. 1100) marks the turning point; and Averroes' spirited defense in *The Incoherence of the Incoherence,* while it showed the accumulated strength of the philosophical tradition, was nevertheless the last outstanding work to be recorded. Philosophy never died out completely; but firmly established religious tradition and mysticism came to be the dominating factors in Islamic life. Thus already Averroes' younger contemporary, the Persian mystic al-Suhrawardi al-Maktul (1155–91), appreciated only the mystical side of Plato's thought and disliked al-Farabi and Avicenna, whose works he knew well; the "intoxicated" mystics were, in his view, true philosophers and true wise men. The great Muslim historian Ibn Khaldun (1332–1406), himself a thinker of the first order, was obviously interested in philosophy and also wrote an epitome of the greater part of Averroes' treatises, which were evidently still studied. Both men were high religious dignitaries. But whereas Averroes saw no difficulty in administering Islamic canon law and upholding the primacy of philosophical reason at the same time, Ibn Khaldun definitely considered philosophy as useless and futile and agreed with the theological critics of Greek theistic philosophy.

PHILOSOPHERS

Al-Kindi.—Yaqub ibn Ishaq al-Kindi (*see* KINDI, AL-), who was flourishing in the first half of the 9th century A.D., followed the Baghdad Mu'tazilite theologians' interpretation of Islam which was officially accepted by the Abbasid caliphs of his day, to whose court society he belonged. But, instead of adhering to the explanation of the world in terms of time and space that most of them favoured (he wrote a treatise against it), he attempted to give to their speculative theology a philosophical counterpart based on Neoplatonic Aristotelianism. He maintained that revealed and natural theology arrive at the same conclusions, but he subordinated philosophy to revelation and reason to the illuminated insight of the prophets.

In several respects the philosophy that he adopts is more akin to the Athenian trend of late Neoplatonism (represented, for example, by Proclus) than to others; but insofar as he, alone among Islamic philosophers, introduces creation out of nothing and the divine decree into metaphysics, he rather reminds us of the Alexandrian Christian philosophers Zacharias of Mytilene and John Philoponus and their attack on the eternity of the world as upheld by most pagan Platonists and Aristotelians and, in due course, by most later Islamic philosophers (John Philoponus is criticized for this very reason by al-Farabi and Averroes). Al-Kindi's description of the Divine Being in negative terms is more consistent than the compromise followed by al-Farabi, Avicenna, Averroes and others. He did not identify "the one" and "the first cause," the eternal source of emanation, with the Aristotelian description of God as supreme intellect, as they did and as Middle-Platonic thinkers had done before. He moved, in this respect, much more on orthodox Neoplatonic ground.

In logic, al-Kindi showed preference for hypothetical and disjunctive syllogisms and was criticized by later philosophers for his neglect of the Aristotelian method of demonstration used by

al-Farabi and others. He believed, like Avicenna, in the immortality of the individual soul but was unable to give philosophical proofs for the resurrection of the body, which he proclaimed as a truth of faith. In conformity with certain Greek Neoplatonists, he accepted astrology as part of philosophy (his pupil Abu Ma'shar became a widely recognized authority in this field), whereas al-Farabi, Avicenna and Averroes rejected it. He was the first philosopher to be familiar with Indian arithmetic. We are still much in the dark about the immediate sources of al-Kindi's philosophy; he lived more than 200 years after the last well-known Greek philosophers in Alexandria.

Al-Kindi succeeded in stating, in very impressive terms, the typical attitude of Arabic philosophers to the Greek legacy; he was conscious at once of his dependence on the Greeks and of his own contribution to the collective experience of the centuries. He says, in the preface of his *First Philosophy:* "It is fitting to acknowledge the utmost gratitude to those who have contributed even a little to truth, not to speak of those who have contributed much [*cf.* Aristotle, *Metaphysics*, 993 a 30]. We should not, then, be ashamed to recognize truth and assimilate it from whatever quarter it may reach us, even when it is brought to us by earlier generations and by foreign peoples. For him who seeks the truth there is nothing of higher value than truth itself; it never cheapens or abuses him who searches for it but ennobles and honours him. We must then remain faithful to the principle that we have followed in all our works: first to record all that the ancients have said about the subject; secondly to complete what the ancients have not fully expressed; and this according to the usage of our Arabic language, the customs of our age and our own ability." Three hundred years later Averroes reaffirmed this cosmopolitan attitude as something obvious; to do as al-Kindi did had become an established practice, and the enthusiasm of the first philosopher had turned into a routine of teaching.

Al-Farabi.—Abu Nasr al-Farabi (*see* FARABI, AL-; d. 950) firmly upheld the primacy of philosophy; philosophical truth is one and the same all over the world. The various religions, he thinks, represent truth in symbolical form adapted to the nonphilosophical mind and are of different excellence and rank. Although he may well have considered Islam the highest of the religions, he had Christian teachers himself and there were contemporary Christian thinkers who were obviously influenced by him and proclaimed similar views. He was, accordingly, very determinedly opposed to all forms of speculative theology (*kalam*), which can have no universal appeal; in this respect he by no means agreed with al-Kindi. He claimed to have revived Greek philosophy (which he believed to be dead in its homeland) in the Islamic world. Philosophy was now no longer content to be accepted in new surroundings; it claimed ascendancy over the other component elements of Islamic life.

Al-Farabi was very much aware of the political aspect of Plato's thought, which most of the Greek Neoplatonists (*e.g.*, Plotinus and Proclus) had disliked. In proclaiming Plato's philosopher-king, he may have been influenced by his own political experience and in any case was consciously speaking as a philosopher in the contemporary debate as to what type of man was best equipped to be caliph (that is, the spiritual and political head of Islam): "If at a given time it happens that philosophy has no share in the government, though every other qualification for rule may be present, the state will remain rulerless, the actual head of the state will be no true king, and the state will head for destruction; and if no wise man is to be found and associated with the acting head of the state, then after some time the state will undoubtedly perish" (*cf.* Plato, *Epistle*, vii).

This "political" attitude (with its emphasis on Plato's *Republic* and *Laws*) was not shared by most subsequent Islamic philosophers (with the exception of Averroes, who also used the *Republic* as a textbook of politics). Avicenna's several encyclopaedias of philosophy have no section on politics at all. Like Plato and the Platonists, al-Farabi was loath to dissociate politics from metaphysics, psychology and ethics; the same hierarchical order which he demands for the perfect society exists in the human soul (if it is properly cared for) and is almost self-evident in the eternally established order of the universe.

Al-Farabi's ultimate source in philosophy was the Neoplatonic school of Alexandria (which had become a Christian school of philosophy during the 6th century); the Neoplatonic doctrine of emanation had been combined with the Aristotelian view of God and of the universe in the teaching of the last Alexandrian Greek thinkers. He showed, as did Averroes after him, a stronger interest in Aristotle's *Physics* than did Avicenna, who only admitted the metaphysical proof of the existence of God and did less justice to the proof based on the analysis of the physical world. As the Greek commentators had done before him, al-Farabi distinguished between different kinds of intellect (*nous*, '*aql*) in the human soul: the passive or potential or material intellect; the actual intellect; and the acquired intellect, the highest grade of perfection which human beings can reach (Avicenna and the Spanish philosophers share this view). He seems to have been the first among Arabic philosophers to introduce the Aristotelian "active intellect" (*nous poietikos*, '*aql fa''al*)—which Alexander of Aphrodisias had identified with the supreme being—as a metaphysical entity mediating between the first cause and the human intellect and actualizing it as light actualizes the colours which already exist potentially. In doing this he probably followed some unknown Greek predecessor who had modified the Neoplatonic universal intellect in this way. There are star intellects (corresponding to "angels" on the religious level; these are to be found in Averroes as well) but no star souls as assumed by Avicenna, who like Averroes accepted the "active intellect" (which al-Farabi equated with the Koranic Angel of Revelation); but apart from this, the physical world is understood on Aristotelian lines. In the account of the soul, Alexander of Aphrodisias is closely followed, but divination and prophetic inspiration are explained in accordance with some otherwise unknown Neoplatonic doctrine. Prophetic inspiration is a function of imagination and hence only ancillary to reason; the perfect man is philosopher and prophet in one and has in addition all the qualities which enable him to govern the perfect state (which may comprehend the whole inhabited world). There is no union with the "active intellect" in life (as Plotinus and, in a different way, the Arabic mystics believed); it is only after life that the souls of the good, *i.e.*, of the philosophers, become part of the "active intellect," thus losing their individuality, whereas the souls of those who knew the truth and acted against it survive in utter wretchedness. The souls of the majority perish at death. The Koranic promises of reward and punishment in a future world have a practical value on the religious level but no philosophical validity.

Miskawayh.—No major treatise on moral philosophy by one of the more representative Islamic philosophers has come down to us. But the work of a not very independent minor thinker, Abu 'Ali Miskawayh (d. 1030), an older contemporary of Avicenna who has some links with al-Farabi's general attitude to philosophy and religion, can be examined instead. His survey of ethics, *Tahdhib al-Akhlak* ("On the Improvement of Character") was influential in later Islamic literature and gives a good idea of the different trends of Greek ethics which appealed to Islamic philosophers. It is an error to think that Aristotle and his later successors were the only authorities recognized by them; many treatises accept as a basis Plato's threefold division of the human soul and his four cardinal virtues (temperance, valour, justice and wisdom). A particularly popular version of this Platonic doctrine, represented in Greek by Galen (who in his turn depends on the great Stoic philosopher Poseidonius), is reported by Miskawayh in great detail. Apart from this, we find in his treatise (but also elsewhere) an interesting combination of the four Platonic virtues, to which numerous subordinate virtues have been added, with the Aristotelian classification of the virtues as means between extremes. It looks as if Miskawayh had become acquainted with this otherwise not very well-attested Greek scheme of ethics through al-Kindi. As in metaphysics and logic, so in ethics, after the time of al-Farabi, the influence of Aristotle is more noticeable. Hence Miskawayh—following ultimately, it seems, Porphyry's exegesis of the *Nicomachean Ethics* and more immediately al-Farabi—insists that Neoplatonic and Aristotelian views must be reconciled in this field as well. Aristotle is an appropriate guide for human happiness, the highest form of which manifests itself in the philosopher's life,

while Plato shows how to prepare oneself for the world to come. This entails, as in other sections of philosophy as well, that Aristotle appears as a more decided Platonist than he actually was. Thus, for instance, Plato's divine *eros* ("love," "desire"), tacitly disowned by Aristotle, comes, as in Neoplatonic and patristic thought, to its full life again. Developing an Aristotelian idea, Miskawayh establishes a new class of friendship based on the absence of passions (*apatheia*), which comprehends the relation of children to their parents, that of the most excellent men, *i.e.,* the philosophers, to God and that of the disciple to his teacher—who is, for the first time in this Aristotelian tradition, qualified as his "spiritual father" and described as a God-like authority (in the Neoplatonic manner). Many other similar instances could be mentioned. Since the study of moral philosophy, as Aristotle (and Plato) had pointed out, can be undertaken only by those who have been properly brought up in their traditional education, the established Islamic law takes the place of the customarily read Greek authors, and Homer is replaced by the Koran. Whereas by al-Farabi, for instance, the religious law is understood as an approach to truth through symbols (which are different in different religions but all tend, though in varying degrees, in the same direction), for Miskawayh the agreement between the divine law and a theistic philosophy is absolute. Hence it is not surprising that the theological critics of Arabian philosophers not only refrained from condemning their ethical teaching but could even take the greater part of it over without reservation (as al-Ghazzali actually did).

Avicenna.—Avicenna (*q.v.;* 980–1037), who lived in Persia and never stayed in Baghdad (as al-Kindi and al-Farabi had done), partly built on the foundations laid by al-Farabi; but there are very marked differences in his philosophical attitude, to be noticed in certain by no means trivial details and, above all, in his emphasis on Plotinian thought wherever he approached the transcendent world. Besides Aristotle, he knew the spurious *Theology of Aristotle* well and even wrote a kind of commentary on this remarkable Neoplatonic work. He also evidently had access to Greek traditions not known to previous Arabian philosophers, as appears from his discussion of the inner senses, of imagination and of animal instinct and from his definition of prophecy as an intellectual acuteness (*agchinoia*) of the highest order—views which seem to be of pre-Plotinian Hellenistic origin. He maintained the immortality of individual souls and supposed them to survive in different forms according to the degree of perfection attained during the time when each was united to a particular body and thus acquired individuality. This was for him the real meaning of the Islamic belief in resurrection.

On the whole, philosophy was for Avicenna the only way of understanding Islam, and Islam as interpreted in Aristotelian and Plotinian terms was the highest and most perfect way of life to be conceived. He successfully applied this rule wherever philosophical and religious traditions overlap; philosophical contemplation of the higher world, reached as the ultimate result of intense and consistent rational training and self-education, takes the place of the personal prayer of the mystic and expresses its true function. Prophecy is no longer confined to imagination or to the creation of impressive symbols of philosophical truth, but is in itself the highest intellectual quality conceivable. Avicenna defined it by a philosophical (and religious) term as *intellectus sanctus* (*qudsi*), thus making it unambiguously clear that philosophical understanding is the only way of establishing the supremacy of prophecy as shown in the Koran and that religion and philosophy do not represent different levels of truth but are one and the same thing (provided that religion be interpreted in philosophical terms).

Plotinian ideas modified Avicenna's view of the world above the moon and made him add star souls and nonintellectual qualities to the transcendent intellects which rule the different astral spheres. The logical concept of essence and the metaphysical concept of existence are identical for the highest being, the "necessary existent": in God alone essence, what He is, and existence, that He is, coincide. God is the first cause, the highest light and the source of all light, as He is the highest intellect and the highest love. There is a gradual pluralization through a timeless emanation from "the one," and, as in most Arabic philosophers, Aristotle's astronomical theory is combined with this Neoplatonic idea. From God, the necessary being, proceeds the first separate intellect, and this is the only emanation which is produced directly by the Eternal Creator ("from one only one is made"). There is a progressive degradation implied in this eternal emanation. The first separate intellect is the source of a threefold emanation: a soul, a body and a second intellect. When it thinks itself as if being in action and owing its existence to the first principle, the soul of the highest heaven proceeds from it; when it thinks itself as not being absolutely necessary but somehow contingent, the celestial body of the highest sphere, the sphere of the fixed stars, proceeds from it; when it thinks its cause, *i.e.,* the necessary being, it produces the intellect of the next sphere, the sphere of Saturn. This creation recurs eternally and timelessly and repeats itself constantly on every level within the world above the moon. Thus the second intellect produces the soul and the body of Saturn and the intellect which rules the sphere of Jupiter. Mars, the sun, Venus, Mercury and the moon follow. There are always an intellect, a soul and a celestial body—Plotinus' universal intellect and universal soul are thus split up into individual separate intellects and individual separate souls. Al-Farabi (who, more Aristotelian than Avicenna, did not assume that star souls exist) had established an additional sphere surrounding the world, located between the highest being and the sphere of the fixed stars. (This sphere can also be found in some works of Avicenna, who is not consistent as far as the number of separate intellects is concerned.) The active intellect is, according to Avicenna, coordinated with the ever-changing world below the moon and the plurality of human souls and human bodies, the world of temporary coming-to-be and passing away. It has, as the bestower of forms (*wahib as-suwar*), the function of the Plotinian *choregos ton logon* and the *dator formarum* ("giver of forms") of scholasticism, and connects man with the higher world of eternal being. The separate intellects and the souls and bodies of the different spheres can all be equated with the angels of Islam.

Avicenna was a vigorous and systematic mind of the highest order and a master in the lucid arrangement of the vast heritage of Greek thought, which he explained again and again in huge philosophical encyclopaedias of varying size. He was well aware of the individual turn that he gave to many tenets of philosophy and accordingly styled himself an "oriental philosopher" as opposed to the "occidental philosophers" of Baghdad. He was less bent on commenting on the ancients than on expounding philosophical thought as such.

Like Rhazes and Averroes, Avicenna was also an outstanding physician; he became famous in the west from the 12th century onward both as a medical and as a philosophical authority. His impact on Islamic life was profound and continued for a long time.

Al-Ghazzali.—Avicenna was, more than any other Islamic philosopher, the target of the determined attack by al-Ghazzali (*see* GHAZZALI, AL-; 1058–1111) mentioned above. Al-Ghazzali denied that philosophy and natural theology can in fact validly prove the existence of God, the creation of the world, the immortality of the soul, the structure of the universe, divine providence and many other problems. He attacked the philosophers on their own ground and tried not without success to defeat them with their own weapons in his work *The Incoherence of the Philosophers*. He re-established, without rejecting a philosophical approach altogether, religion and prophetic inspiration in their own right and in their superiority. His answer to the inner tensions of Islamic life turned out to be more acceptable and more appropriate to the very spirit of Islam than Avicenna's attempt to identify philosophy and religion in imitation of the Greek religion of the mind. Hence it is with him that the definite though gradual decline of Arabic philosophy begins.

Averroes.—Spanish Arabic philosophy, however (continuing the development which started in the 9th century in the east), did not begin much before al-Ghazzali's time. It is represented by Avempace (*q.v.;* d. 1138), by Ibn Tufail (*q.v.;* d. 1185) and, above all, by Averroes (*q.v.;* 1126–98). It depends to a large extent on al-Farabi and is, accordingly, very critical of Avicenna, who was

well known to all the Spanish Arabic philosophers and particularly to Averroes. Averroes' scholarly and scrupulous commentaries on Aristotle seem not to have found many Arabic readers, but a great number of them were almost at once translated into Hebrew and into Latin and became very important for Aristotelian studies, both Christian and Jewish, up to and beyond the days of the Italian Renaissance. In these commentaries Averroes continued, with some originality, the tradition established in late Greek philosophy which had reached the Arabs in the days of al-Farabi. Following this great predecessor, he even applied himself to the exegesis of Aristotle's *Poetics* and *Rhetoric* and of Plato's *Republic*. His most independent work, indeed almost the most impressive book written by any Arabic philosopher, is his defense of philosophy against al-Ghazzali, entitled *The Incoherence of the Incoherence,* in which he made a supreme effort to show that only philosophy could give a satisfactory answer to the questions raised. He reproached al-Ghazzali for having made God an immortal man, whereas He is in truth the nonhuman and transcendent first cause of all being. His view of the relation between philosophy and religion is almost identical with that of al-Farabi. The so-called Latin Averroists misinterpreted their master in ascribing to him the doctrine of a double truth, namely, that what is true for religion may be false for philosophy. What Averroes maintained was that the same truth may be expressed either in philosophical or in symbolic form.

A doctrine of Averroes which became particularly well known in the Christian west is the doctrine of the unity of all human intellects. Some adhered to it, others rejected it, and the church eventually condemned it as heretical. Averroes adopts the distinction between the material, actual and acquired intellects that is to be found, among Arabic philosophers, already in al-Farabi (*see* above). The human or material intellect is, for Averroes, eternal and is no part of the essence of the individual soul but one and the same for all mankind. In opposition to Aristotle (*De anima*, 430a 23) he can thus, through his Neoplatonic interpretation of the Peripatetic doctrines, regard the passive or material intellect as incorruptible. The active intellect transmits the *intelligibilia* for this material intellect, which, in grasping them, becomes, in a particular individual, first actual and then acquired intellect. Although different persons differ in intelligence and knowledge thus obtained, there is always the same amount of intellectual knowledge in the world. "Scientific knowledge is eternal, ungenerated and incorruptible. By being connected with Socrates or Plato, it perishes when these persons die, but this is accidental and does not impair its essence." For the influence of Averroes on scholastic philosophy in western Europe *see* AVERROISM, LATIN.

Rhazes and the Ikhwan al-Safa.—Such was the highroad of Islamic philosophy, which was still followed for some time after Averroes in various parts of the Islamic world; but two sidelines deserve to be mentioned.

Rhazes (*i.e.*, Mohammed ibn Zakariyya al-Razi; d. 923 or 932) went so far as to disapprove of all the prophets as impostors and promoters of discord among the nations and to see no road to salvation but through philosophy. He rejected both the eternity of the world and creation out of nothing and believed in a divine formation of the world in time out of eternally existing matter. There are five eternal principles, not one as in the other systems: the Creator, the soul of the world, matter, absolute time and absolute space. He wanted to be considered as a Platonist, but was at the same time prouder of his independent judgment than any other Arabic philosopher. He assumed an atomic structure of matter which can only be compared with Democritean and Epicurean doctrines.

The writings of the 10th-century brotherhood known as the Ikhwan al-Safa, which represent philosophical doctrines accepted by the Ismaili movement, are the chief but by no means the only evidence of another influential trend of Arabic philosophical speculation. This in its origin may be earlier than al-Kindi, although it has certain affinities with his general philosophical outlook. It may be characterized as a simplified but rather orthodox Neoplatonism without the admixture of so many Aristotelian elements as are to be found on the main line of Arabian philosophy from al-Farabi to Averroes.

The Kalam and al-Ash'ari.—A word should be said here about the Greek philosophical ideas which had been adopted by Muslim speculative theologians even before the rise of philosophy under the Mu'tazilites and which in the form given to them in the school of al-Ash'ari (10th century) came ultimately to have a stronger impact on Islamic life than the Aristotelian-Neoplatonic trend of Greek provenance. This speculative theology is called *kalam* and its representatives are the *mutakallimun* (*dialektikoi*, "dialecticians"). In its early stage, the *kalam* was merely a defense of Islam against Christians, Manichaeans and believers in other religions; but as the influence of philosophy increased (quite apart from the independent growth of theological speculation) it came to be directed also against the Islamic synthesis of Aristotle and Plato, and arguments which the Greek skeptics and the Stoics had found effective against those two philosophers were employed. The *mutakallimun* rejected potentiality in the Aristotelian sense; possible and actual are identical for them, and before the fact nothing is possible. Hence they would not accept the philosophers' theory of movement and of becoming or the metaphysics and natural theology based on that view. As the Eleatics and the Megarians had done before, the Ash'arites denied becoming and transition in time and movement in space altogether and spoke of "timeless leaps" instead; what we call movement is for them the being of a material atom at the next time-atom in the next space-atom. This implies a peculiar atomic structure of nature which is very different from the Democritean and Epicurean atomism, with which Rhazes was familiar. There are only atoms and "accidents" connected with them by God. There is no natural law and no natural causation but a material passive universe. God is the only agent, the sole active principle, who as the omnipotent transcendent Allah discontinuously creates and recreates His atomic world. It is improbable that this atomic theory depends on Indian views, as has been suggested; links with Greek thought seem to be more obvious.

In ethics, the Ash'arites adopted a determinist view and borrowed Stoic arguments in support of it.

ARABI PASHA (properly AHMAD URABI PASHA) (1839–1911), Egyptian nationalist leader, was born of peasant stock near Zagazig, in Lower Egypt. He was conscripted into the army and later commissioned (1862). In the Egyptian-Ethiopian war of 1875–76 he served as a commissariat officer. He joined a secret society formed by Ali al-Rubi (later created pasha), a brother officer, with the object of eliminating the Turkish-speaking (mainly Circassian) officers who monopolized the higher ranks of the army. After playing a subordinate part in the officers' mutiny of 18

he was promoted colonel and began to win great popularity among the Egyptian troops as the embodiment of their resentment against foreign control whether Turkish or European. When, early in 1882, Mahmud Sami al-Barudi Pasha (Egyptian patriot and poet, a Circassian by origin) became prime minister, Arabi, with the rank of pasha, was his minister of war, and such was his growing influence that the British government showed alarm and sent a fleet to Alexandria, a gesture which led to riots in which many Europeans were killed. Arabi took command of the rebel forces and put the harbour forts in a state of defense. On the refusal of the French to co-operate, British warships silenced the forts on July 11, 1882. A British expeditionary force under the command of Sir Garnet Wolseley landed at Ismailia on the Suez canal and on Sept. 13 defeated Arabi's army at Tall al-Kabir (Tell el-Kebir). Arabi surrendered in Cairo, where he was tried for sedition. He was sentenced to death, but the sentence was by previous arrangement changed to one of banishment. He and other nationalist leaders were banished to Ceylon, but after an exile of 19 years he was pardoned and returned to Egypt in 1901. He died in Cairo on Sept. 21, 1911. Though not a great leader and certainly no soldier, his popularity rested on his simple, kindly disposition.

Bibliography.—J. Ninet, *Arabi Pacha* (1884); A. M. Broadley, *How We Defended Arabi and his Friends* (1884). There is a copious literature devoted to Arabi in Arabic. (R. L. Hl.)

ARABIS, a genus comprising more than 100 species of annual, biennial and perennial herbs, commonly known as rock cress, belonging to the Cruciferae (*q.v.*) family. The usually numerous small, white, pink or purple flowers are borne in terminal spikes or racemes. The species are widely distributed in the northern hemisphere, and *A. albida*, the wall cress, a white-foliaged plant from the Caucasus, is a popular garden perennial for gritty soil or pockets in a wall. Its white flowers are especially fragrant. It has many fine horticultural varieties with pink, yellow and double flowers and one with variegated foliage. Ten other species are cultivated, mostly in British gardens. (N. Tr.)

ARABISTAN, Persia: *see* Khuzistan.

ARAB LEAGUE. The Arab League came into being on March 22, 1945, when the seven Arab states (Egypt, Syria, Lebanon, Iraq, Transjordan, Saudi Arabia, and Yemen) that had become independent since 1919 signed a covenant in Cairo, Egy., forming a loose confederation. The objects of the league, as stated in the covenant, were "to strengthen the ties between the participant states, to coordinate their political program in such a way as to effect real collaboration between them, to preserve their independence and sovereignty and to consider in general the affairs and interests of the Arab countries." A league council was to implement this program. On it each member state was to have one vote, and decisions were to be binding only if unanimously reached. A permanent secretariat was set up in Cairo, and the first secretary-general was the Egyptian 'Abd-al-Rahman 'Azzam (succeeded in September 1952 by another Egyptian, Mohammed 'Abd-al-Khalek Hassuna).

This league fell far short of the ideal of Arab unity which had inspired the Arab movement since its early beginnings in the 19th century. In the period between World Wars I and II, the aspiration to unity came into conflict with local identities and interests in the states created by Great Britain and France and also in Egypt. The Arab states in 1945 found it impossible to embody the idea of greater Arab unity in anything more than a league of sovereign states.

However, the league covenant contained a provision permitting any two or more of its members to enter into a closer form of association than the covenant itself set up. Another significant provision was that Arab countries still under foreign control should have the right to join the league on attaining independence—a right of which Libya (1953), the Sudan (1956), Tunisia and Morocco (both 1958), Kuwait (1961), and Algeria (1962) availed themselves, thus bringing up the membership of the league to 12 states (considering Egypt and Syria as one country, the United Arab Republic).

From the beginning the league was handicapped by differences among its members. These first became clear during the military intervention it attempted in 1948 in Palestine to prevent the establishment of the state of Israel. The intervention was unsuccessful because it lacked unity of purpose and coordination of effort. The league survived, but the differences reappeared in one form or another thereafter. The league's existence may have helped the Arab states to coordinate their policies toward problems of general interest, like those of Palestine and Algeria; but it was not found possible to create a closer political unity. In 1950 the members signed a joint defense treaty setting up a system of collective security; but in the next few years the split between Egypt and other Arab countries which followed a neutralist policy and those with a more pro-Western alignment, as well as local disputes, prevented cooperation except at the moment of the Suez crisis in 1956. In 1961 the disputes were sufficiently composed for the league to hold a council meeting in Baghdad at which all members were present. In the same year the conflict between Tunisia and France provided an occasion for a display of unity, although Iraq's claim to Kuwait subjected the league to internal strain. In spite of Iraq's objection the league admitted Kuwait to membership and raised an Arab force which replaced British troops in Kuwait.

In the following years the plans of the Israeli government in regard to use of the waters of the Jordan River led to further attempts to work out a united Arab policy. In January 1964 a "summit conference" of heads of states, held in Cairo, agreed on a counterdiversion of the Jordan headwaters and the establishment of a joint Arab command. A second summit conference was held at Alexandria in September 1964, a third at Casablanca in September 1965. But this effort also came to nothing, because of disagreements, and in particular because of the civil war which broke out in Yemen in 1962 and into which Egypt and Saudi Arabia were drawn. The fourth summit conference, which was to have been held at Algiers in September 1966, was postponed.

In spheres other than the political the league has proved somewhat more effective. The Economic Council and the economic section of the league's secretariat have done something to strengthen economic ties; but the Arab Development Bank created in 1959 has been inactive. The Boycott Office has had some effect in organizing an economic boycott of Israel. The annual petroleum conferences have provided for the discussion of oil problems, and other specialized conferences and seminars have been held. The Institute of Advanced Arab Studies and the Institute of Arabic Manuscripts, both in Cairo, have done useful work.

ARACAJÚ, a city and seaport of Brazil, capital of the state of Sergipe (*q.v.*), 170 mi. N.N.E. of Salvador. It is on the right bank of the Cotinguiba, or Cotindiba river, 6 mi. from the coast at the base of a ridge of sand hills. The *municipio* of which it forms a part had a population in 1890 of 16,336, about two-thirds of whom lived in the city itself. Pop. (1950) 78,364, mun.; 67,539, city; (1960) 112,516, city.

Good limestone is quarried in the vicinity of Aracajú, and the country tributary to the port produces sugar and cotton. The back country sends down hides and goat skins for shipment. Electric power comes from the Paulo Afonso falls (*q.v.*). The anchorage is good, but a dangerous bar at the mouth of the river prevents the entrance of vessels drawing more than 12 ft. The river is navigable as far as the town of Maroim, about 10 mi. beyond Aracajú.

The city was founded in 1855. (R. d'E.; P. E. J.)

ARACEAE (Aroideae), the arum family, a large group of monocotyledonous plants containing upward of 100 genera and more than 1,000 species, of which the cuckoopint in Great Britain, and the jack-in-the-pulpit, found in eastern North America, are familiar examples. Neither of these small plants, however, gives more than meagre indication of the characters of this interesting plant family, which attains its most conspicuous development in the tropics.

The aroids are generally herbaceous, often, however, reaching gigantic size; but they are sometimes shrubby climbing plants.

Many are peculiar in form and habit and grotesque in appearance. Various climbing species of *Philodendron* have feeding roots which penetrate the soil and clasping roots that fix the plant to its support. Some are epiphytes (plants that grow perched upon others), and a few, such as the water lettuce (*Pistia stratiotes*), are floating plants.

The leaves, which show great variety in size and form, are generally broad and net veined, though sometimes sword shaped and parallel veined. In *Arum* the blade is simple. In other genera the leaves are divided and sometimes very large; those of *Dracontium* (tropical America) may be 15 ft. high. In the ceriman (*Monstera*) the large perforated leaves appear as if cut full of holes. The small flowers are crowded on thick, fleshy spikes (spadix), which are usually enveloped by a large leaf (bract), the spathe, which is often the most conspicuous feature of the plant. For example, in the cuckoopint the spathe is large and green; in the jack-in-the-pulpit it is purple-striped; in the callas it is white or yellow; and in the anthuriums it is scarlet. In *Amorphophallus*, a genus of about 80 species characteristic of tropical Asia and Malaysia, the "flower" (really an inflorescence consisting of the spathe and the spadix) varies from a few inches to several feet in diameter. The largest is the *krubi* of Sumatra, *Amorphophallus titanum*, its spathe being up to 4 ft. in diameter and its spadix attaining a height of 8½ ft. While this has been claimed to be the largest flower in the world, it is really an inflorescence, its numerous individual flowers being small in size. The true flowers are often extremely simple, sometimes, as in *Arum*, reduced to a single stamen or pistil. The fruit is a berry. Usually the plant tissues are exceedingly irritating when brought in contact with mucous membranes, because of the presence of myriads of minute needlelike crystals (raphides) of calcium oxalate in the plant cells. The raphides are responsible for the pungent taste. Historically the extract has been used in medicine as a carminative. The underground stems (rhizomes or tubers) are rich in starch, those of the tropical taro (*q.v.*) providing a valuable article of food. From the rhizomes of the cuckoopint Portland arrowroot was formerly prepared. The starchy corms of the jack-in-the-pulpit, after proper treatment to eliminate the raphides, were utilized for food by the Indians of eastern North America.

T. H. EVERETT

ANTHURIUM ANDRAEANUM, ORNAMENTAL SPECIES OF ARACEAE, FOUND IN COLOMBIA

Besides the cuckoopint, the *Acorus calamus* (*q.v.*) or sweet flag occurs in Great Britain, though it is supposed to have been introduced. In North America about 15 native species of aroids are found, chiefly in the southern and eastern United States. Among these are the jack-in-the-pulpit, golden club, skunk cabbage (*qq.v.*), green dragon, water lettuce, wild calla (*see* CALLA) and sweet flag. Only one, the western skunk cabbage (*Lysichiton*), occurs on the Pacific coast.

In tropical America taro (*Colocasia*) is replaced in cultivation by the yautia (*Xanthosoma*) which, like the taro, is an important food plant. Because of their unusual foliage and inflorescence, numerous species of *Alocasia, Anthurium, Caladium, Colocasia, Dieffenbachia, Scindapsus, Xanthosoma* and other genera are grown in greenhouses for ornament and as curiosities.

A good series of tropical aroids may be seen in the aroid house at Kew, and in the United States in the display greenhouse of the New York Botanical garden in the Bronx, New York city. Perhaps the best collection in tropical gardens is that in the Botanic Gardens of Indonesia at Bogor, Java.

ARACENA, a town of Huelva province, Andalusia region, southwest Spain, is situated on the southern slopes of the Sierra de Aracena, 94 km. (57 mi.) by road N.W. of Seville. Pop. (1960) 7,643 (mun.). The parish church of the Assumption has fine sculpture by Juan Martínez Montañés. The 13th-century castle church is situated on the summit of the hill on which are the ruins of the castle, and has three naves and an apse shaped like a polygon (13th century). There is a gateway of the former convent of Santa Catalina and a 12th-century tower remaining from the mosque. The bracing climate and the Gruta de las Maravillas, which has a subterranean lake and a great number of stalactites and stalagmites in weird shapes and beautiful colours, attract many tourists.

ARACHNE, in Greek mythology, the daughter of Idmon of Colophon in Lydia, a dyer in purple. She had acquired such skill in the art of weaving that she ventured to challenge Athena. The goddess wove a tapestry depicting the gods in majesty, while Arachne showed their amorous adventures. Enraged at the perfection of her rival's work, Athena tore it to pieces, and Arachne hanged herself in despair. But the goddess out of pity loosened the rope, which became a cobweb, while Arachne herself was changed into a spider (related by Ovid in the *Metamorphoses*). The name Arachne means spider. An ancient illustration of the story can be seen on a frieze from the Forum of Nerva in Rome.

(T. V. B.)

ARACHNIDA, a class of the phylum Arthropoda (*q.v.*) that includes spiders, scorpions, daddy longlegs (harvestmen), mites, ticks and many other less familiar forms. Arachnids are a ubiquitous group: the great majority of them are land animals, encountered in a variety of habitats throughout the world. They are chiefly predators, subsisting on other arthropods. Their characteristics are typically arthropodan: paired, jointed appendages; anterior sense organs; and a hardened outer covering (chitinized exoskeleton). They are distinguished in part from other arthropods by having a body divided into two principal regions, six pairs of appendages and only simple eyes.

Arachnids are variable in both size and appearance. They range from tiny mites no more than 0.1 mm. long to the enormous black scorpion of Africa that is 180 mm. (slightly more than 7 in.) long. In form they vary from small rounded, inconspicuous kinds to long-legged, agile runners; crablike spiders; and elongate fast-running predators.

VIII. Classification

I. INTRODUCTION

The following living orders are included in the class Arachnida: Scorpiones (or Scorpionida) (scorpions); Pseudoscorpiones (or Chelonethida) (false or book scorpions); Acari (or Acarina) (mites and ticks); Opiliones (or Phalangida) (harvestmen, or daddy longlegs); Schizomida (schizomids); Palpigradi (palpigrades); Phrynichida (tailless whip scorpions); Thelyphonida (whip scorpions); Araneae (or Araneida) (spiders), Ricinulei or

Podogona (ricinuleids) and Solifugae or Solpugida (solpugids, or sun spiders). In addition, five fossil orders are known from strata dating no later than the end of the Upper Carboniferous (about 235,000,000 years ago).

At times the "horseshoe crab" (*Limulus*) is included in the Arachnida, but because of certain features of its anatomy and life habits it is usually awarded a class of its own, the Merostomata.

For a more detailed classification see *Classification* below.

1. Distribution.—Although the number of arachnids encountered in the temperate portions of the world is truly impressive, the number and variety is even greater in the tropical and subtropical zones. In both temperate and tropical areas, spiders are the most conspicuous arachnids; the smaller mites and ticks, however, exceed them in numbers. Opilionids and pseudoscorpions likewise are abundant in temperate areas, and a few scorpions may be found in milder climates. In tropical and subtropical areas scorpions are frequently encountered along with schizomids and palpigrades under leaves, stones or fallen logs. The thelyphonids are often conspicuous and abundant, as are the solpugids. Spiders are everywhere.

Arachnids of various kinds may be found in all parts of the habitat. Thus some dwell chiefly in shrubs, herbs and trees, others on the ground, and still others are encountered only under fallen leaves, twigs, logs and stones. Spiders are the most diverse of the arachnids in their structure, habits and distribution. Many of the tarantulas of the United States and Central and South America make elaborate silk-lined burrows in the ground in which they live for several years. Young spiders are able to utilize a strand of silk as a "balloon," and as a result, may drift to very high altitudes or far from land.

2. Relationships.—Members of the phylum Arthropoda, to which the arachnids belong, have many characteristics such as a segmented body, paired appendages and anterior sense organs in common with the segmented worms (phylum Annelida). The arthropods have of course gone far beyond the annelids in their evolutionary development and have added a chitinous exoskeleton and jointed appendages. The arachnids are related to other arthropods such as the crustaceans, millipedes, centipedes, insects and horseshoe crabs. Their possession of four pairs of walking legs (instead of three pairs) and lack of antennae, wings and compound eyes distinguish the arachnids from all other arthropods.

II. EXTERNAL ANATOMY

Typically, arachnids have a body divided into two principal portions, the cephalothorax (the joined head and thorax) and the abdomen. Segmentation of the body is very variable among the different orders. Six pairs of jointed appendages are present: the first pair, the chelicerae (sing. chelicera), are prehensile and are used to hold or grasp prey; the second pair, the palpi (sing. palpus), or pedipalps, may be leglike organs of touch (tactile organs) or large chelate (pincerlike) raptorial organs; and the remaining four pairs are so-called walking legs.

1. Segmentation.—The segmentation of the adult arachnid is not the same as that of the embryo. Presumably the embryo has the original, primitive number of 21 longitudinally arranged segments (somites). The exact number, however, is not certain, for it is difficult to determine the number of somites in the head region. The thoracic portion of the cephalothorax is believed to be composed of five somites, and the abdomen of 12. This original number is retained in the adult segmentation of thelyphonids, schizomids, phrynichids, pseudoscorpiones and some spiders. The adult scorpion also has 12 somites in the abdomen: although the first one is reduced, the eighth is subdivided so that the total number is still 12.

A commoner condition is that in which there is either a partial or complete loss of segmentation either through a fusion of somites or through their disappearance beginning with the last somite and progressing forward. The solpugids and palpigrades have only 11 somites in their abdomens, for the 12th has been lost. Most spiders have lost as many as seven posterior somites. The first abdominal somite forms a slender pedicel by which the abdomen is attached to the cephalothorax, and the second to fifth somites fuse. Among the acarids external segmentation is usually lacking.

In those arachnids having segmented abdomens, the sternites (ventral plates of the somites) are also subject to fusion, resulting in a smaller number of sternites than that of tergites (dorsal plates). The second and third sternites show all degrees of fusion, with some fusing to form a single plate. Among the pseudoscorpiones each sternite is subdivided by a longitudinal line into a pair of scuta. The tergites are less subject to fusion than are the sternites, possibly because the first sternite is crowded out by the basal segments (the coxae—sing. coxa) of the fourth pair of legs. Nevertheless, as many as eight tergites may be completely fused and form a single dorsal plate with the carapace. This is true among the opilionids. Among the pseudoscorpions, the tergites are subdivided by longitudinal lines, and a superficial segmentation (not reflecting the true segmentation) is found among some acarids.

The telson and cucullus are movable structures that have no relationship to the true embryonic segmentation. The telson is a dorsal postanal outgrowth of the body wall, articulated to the anal segment; it may be single-jointed as in scorpions in which it is developed as a sting or composed of numerous segments as in whip scorpions. The cucullus is a dorsal hoodlike plate articulated to the anterior edge of the carapace among the ricinuleids. It also is an outgrowth or fold of the dorsal body wall.

2. Cephalothorax.—The head and thorax of the arachnids form a single unit, the cephalothorax. This is true even in animals such as the solpugids that have evident thoracic segmentation as adults. If the fusion of the thoracic somites with the cephalic ones is complete, the dorsal surface of the cephalothorax is protected by a chitinous shield, the carapace. This condition is found among the scorpions, pseudoscorpions, thelyphonids, phrynichids, spiders and ricinuleids. When only one, two or three thoracic somites are completely fused with the head and the following ones remain independent and have their own dorsal plates (tergites), the segmented carapace is divided into three portions. The first (peltidium) forms the front and extends over the first two pairs of walking legs, the second (mesopeltidium) is over the third pair of walking legs, and the third portion (metapeltidium) is over the fourth pair of walking legs. This is characteristic of the schizomids, palpigrades and solpugids.

Most arachnids have eyes that are situated on the carapace. They are always simple eyes (ocelli), never compound.

The ventral surface of the thorax is occupied chiefly by the basal segments (coxae) of the appendages. Those portions of the thoracic ventral wall that are retained are represented by the underlip and the sternum. The sternum may be a single plate as

in spiders, or three or four sternites. The number and structure of the sternites are characteristic for each order and show considerable variation.

Appendages.—Typically, arachnids have six pairs of appendages on the cephalothorax. Among the mites there are exceptions to this generalization: larval mites frequently have only three pairs of legs; the eriophyids have only two pairs of legs in all stages; and two other families have only three pairs of legs as adults or at times only a single pair.

The first pair of appendages, the chelicerae, are not invariably chelate (pincerlike). Some are retrovert; that is, the claw opens and closes like the blade of a pocket knife. The immovable "finger" of the distal (end) segment of the chelicera is merely a process of the body wall, not an independent segment as is the movable finger. Chelicerae may be two-jointed, as in spiders, or three-jointed, as in scorpions; in the embryo of all orders they are postoral, but in the adult they are always preoral. The chelicerae usually function as mouthparts but often have other important functions as well.

Among the solpugids the males use the chelicerae to transfer sperm into the genital opening of the female. Among the spiders the fanglike process of the distal segment of the chelicerae is perforated by the duct of the poison gland, the poison being injected into the wound inflicted by the fangs. In pseudoscorpions the movable finger of the chelicerae bears a galea (spinneret) through which silk produced by a special gland is passed. Chelicerae are often provided with sound-producing devices (organs of stridulation), as in many spiders and solpugids. Among the thelyphonids and the mygalomorph and liphistid spiders, the terminal joint of the chelicera moves up and down in a plane parallel to the body. The fangs of other spiders and the movable fingers of the chelicerae in scorpions moves in and out laterally.

The second pair of appendages is the palpi. Each palpus usually has six segments: the basal joint, or coxa, which may have a chewing or crushing jawlike process (the "maxillary"); the trochanter; femur; patella; tibia; and tarsus. In scorpions and pseudoscorpions the palpi are powerfully developed, the last two joints forming a "hand" with two fingers acting as pincers. One of these fingers is always immobile and is merely a process of the hand; the other finger is movable. The hand of pseudoscorpions bears a poison gland, the duct of which opens at the tip of the immobile finger. The palpi of thelyphonids and phrynichids, also powerfully developed as grasping organs, are termed raptorial. The palpi of solpugids have a tactile function and are used occasionally in locomotion. Stridulating organs are found on the trochanter of the palpi in many spiders. The most remarkable modification of the palpi, however, is found in all male spiders; in these forms the terminal joint is developed as an organ of copulation.

Each leg of the four pairs of walking legs usually has seven segments: the coxa, trochanter, femur, patella, tibia, metatarsus and tarsus. The placement of the coxae is typical for whole orders of Arachnida, with some variation among species occurring within any one order. In scorpions the coxae of the first and second pairs of walking legs are provided with somewhat elongate processes, the gnathobases, that bear maxillary glands producing digestive enzymes. In opilionids the coxa of the first walking leg and occasionally that of the second also have gnathobases, but in all other arachnids gnathobases in coxae of walking legs are lacking. The trochanter forms the "hip" joint and usually is very short, with only a single point of articulation with the coxa. Among spiders and opilionids this articulation is a weak point and the animal can cast off the leg if it is injured or trapped. Among some arachnids the trochanter is subdivided into two joints, or a piece of the femur becomes independent and assumes the function of a second trochanterial joint. The "knee" is formed by the articulation of the femur with the patella; the latter can move only up and down. The articulation of the tibia with the patella is in a plane at right angles to the knee articulation. The upward movement of the metatarsus, like that of the patella, cannot go beyond the complete extension of the leg when the axis of the joints forms a straight line. Further upward motion of the foot is therefore restricted to the tarsus. The tarsus, the "foot" proper, is usually single-jointed and rigid but may be composed of several segments or of many secondary subdivisions and may show considerable flexibility, as in opilionids and some spiders.

The first pair of so-called walking legs in thelyphonids, schizomids and phrynichids is modified as tactile organs. Among most opilionids the second pair of legs is tactile and the first is used for walking. The ricinuleids have the third pair of legs modified for copulation, special devices on the metatarsi and tarsi being used for that purpose. Among the solpugids the coxa and trochanter of each leg of the fourth pair are supplied with special sense organs in the shape of stalked plates, the malleoli or racket organs.

With few exceptions the legs end in one, two or three claws. An adhesive pad is often present, formed either by modified hairs that are flattened and supplied with minute barbs holding them together, or by concave, sometimes trumpet-shaped, pads known as arolia. Adhesive structures are usually present only on legs with two claws; this is always the case when the structure is an arolium. Hairs adapted for clinging, however, occur among some spiders that have three-clawed legs.

3. Abdomen.—The abdomen of arachnids may be broadly joined to the cephalothorax, as in the opilionids, scorpions, pseudoscorpions and mites, or narrowly joined by means of a stalklike petiole, as in the palpigrades, thelyphonids and spiders. The sexual ducts usually open on the second segment, beneath the base of the abdomen in all arachnids but the acarids. Among the spiders a special chitinous structure (the epigynum) present around the genital openings of the females, is useful in classification.

Appendages.—Abdominal appendages, which appear as round knobs in the embryo of most arachnids, disappear before completion of development. Among scorpions the abdominal appendages of the third body segment (somite) develop into combs that persist throughout life. These appear to detect ground vibrations. In spiders each embryonic knob of the fourth and fifth somites becomes forked (biramous) during development, forming four pairs of silk-spinning nipples called spinnerets; all other rudiments of abdominal appendages disappear. In most spiders, however, the inner branches of the first pair of the developing spinnerets disappear, so that only six spinnerets remain. The disappearance of more spinnerets results in only four being present in the mygalomorphs and some other spiders and only two in other forms. Among the cribellate spiders the inner branch of the rudimentary abdominal appendages of the fourth somite flattens out and becomes perforated by numerous openings for the ducts of special silk glands, forming the cribellum. The nipplelike colulus of noncribellated spiders is the last remnant of the same branches but is without the corresponding silk glands. The book lungs also may represent modified abdominal appendages.

4. Sense Organs.—Most arachnids have simple eyes (ocelli) situated on the carapace. The corneal lens is discarded and replaced by a new one at every molt. The cells that produce the lens are themselves modified and form a transparent "glass" body. The lens may be spherical, oval or even irregularly triangular, as in some spiders. The light-sensitive retina is direct in the median pair of eyes (anterior median in spiders) but inverted in lateral eyes. Images formed on the retina vary in sharpness and size, depending upon the shape of the lens. The fields of vision are determined by the position of the eyes on the carapace.

The acuity of vision is always less than that of vertebrates and is different for each pair of eyes in the same individual. Scorpions may have as many as five pairs of lateral eyes in addition to the median pair. Opilionids have only median eyes. Some arachnids are blind. Eyes with an inverted retina often have a layer (tapetum) of pigment cells that reflect light and give the eyes a pearly appearance. Such eyes have been termed nocturnal in contrast to those eyes lacking a tapetum.

The best developed sense among arachnids is the sense of touch. Sensory hairs of various types are found all over the body but chiefly on the appendages. One type, known as trichobothria, is sensitive to currents of air.

Crab spider (*Misumen[illegible] aleatorius*), white in summer turning to yellow in autumn

Black widow (*Latrodectus mactans*), with red mark on underside of abdomen, is venomous but rarely fatal to adult human

Scorpion (order Scor[illegible]). Smaller forms, like those found in southwestern U.S., are moderately venom[illegible]

Spiny-bodied spider (*Micrathena sagittata*), marked by its fearsome-looking spines and vivid colour

"Tarantula" (*Dugesiella hentzi*), among the largest of American spiders, is, contrary to popular belief, harmless to man

Striped harvestman (*Leiobunum vittatum*), though spiderlike is not a spider but a phalangid

ARACHNIDS

PHOTOGRAPHS, (EXCEPT LEFT CENTRE) JOHN H. GERARD, (LEFT CENTRE) ENCYCLOPÆDIA BRITANNICA FILMS; IDENTIFICATION OF SPECIMENS (EXCEPT LEFT CENTRE) BY WILLIS J. GERTSCH, AMERICAN MUSEUM OF NATURAL HISTORY

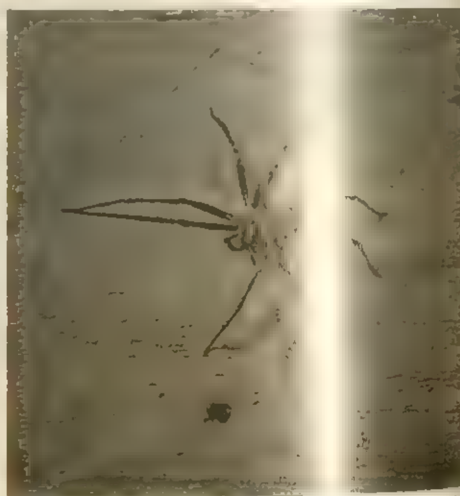
ARACHNIDA

Hunting spider (*Castianeira longipalpus*), aptly named because it does not lie in wait for its prey

Stick spider (*Tetragnatha elongata*) has elongated body and legs that ... nes camouflage among branches

Golden garden spider (*Argiope aurantia*) is found throughout the U.S. It is an orb-weaving species

Mite (suborder Trombidiformes). Some are smaller than a pinhead



Brown spider (*Loxosceles reclusus*) a venomous species found in Missouri and neighbouring states of the U.S.

Wolf spider (*Lycosa aspersa*), like the hunting spider, chases and captures its prey

Say's harvestman (*Libitiodes sayi*), of an order entirely different from spiders

ARACHNIDS

PHOTOGRAPHS, JOHN H. GERARD; IDENTIFICATION OF SPECIMENS BY WILLIS J. GERTSCH, AMERICAN MUSEUM OF NATURAL HISTORY

The olfactory sense seems to be restricted to sexual odours, though strongly irritant substances are detected. It appears that the minute lyriform slit organs situated on the appendages of some forms are olfactory in function.

Although many arachnids have sound-producing organs, no sense of hearing has been demonstrated in the group.

III. INTERNAL ANATOMY

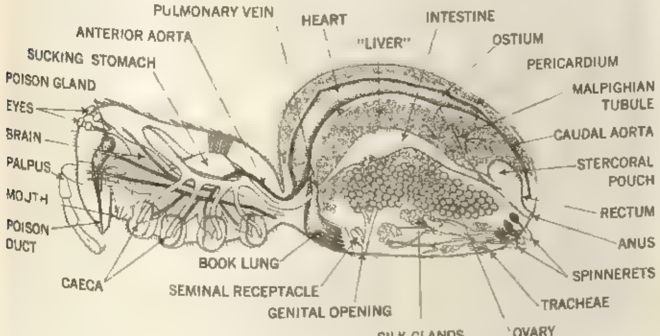
1. Endoskeleton and Musculature.—All arachnids possess an endoskeleton located in the cephalothorax and in the abdomen. In the cephalothorax the endoskeleton consists of a chitinous endosternite and pocketlike apodemes, both of which originate as invaginations of the body wall. In the abdomen the endoskeleton consists of apodemes alone. Both elements serve for the attachment of muscles.

The muscular system is extremely complex. Some muscles hold the endosternite in place and act as the locomotor muscles of the palpi and legs. Other muscles in the cephalothorax are those moving the chelicerae and those expanding the pharynx and gizzard. At the posterior end of the cephalothorax are the muscles attached to the abdomen; these are especially developed in those arachnids having a petiolated abdomen. The abdomen itself contains many muscles including segmentally arranged longitudinal dorsal and ventral muscles of the abdominal wall; dorsoventral muscles; muscles moving the combs in scorpions, the spinnerets in spiders; etc. Within the appendages also are many muscles.

2. Digestive System.—The alimentary canal of arachnids is divided into three portions. The anterior portion, or fore-gut, and the posterior portion, or hind-gut, are ectodermal in origin and their chitinous lining is replaced by a new one at every molt. The middle portion, or mid-gut, has an endodermal lining and is without a chitinous lining. The three sections of the alimentary tract have more or less the same structure in all arachnids but vary considerably in detail, and are more or less correlated with the method of feeding.

Fore-gut.—The fore-gut serves for the passage of food into the mid-gut, where the food is digested. In many cases the fore-gut serves also for the outward passage of digestive enzymes through the wound inflicted by the chelicerae into the body of captured prey for predigestion. In its highest development in the spiders, the fore-gut consists of a pharynx, an esophagus and a gizzard. The pharynx is a complex organ acting both as a pump for sucking in food and a sieve for preventing coarse particles from passing into the esophagus. The esophagus is merely a conducting tube that passes ingested fluid into the gizzard, a second powerful pump aiding both in ingestion of food and in its passage into the mid-gut. In opiliones the pharynx has no straining action; thus these arachnids are capable of ingesting fairly coarse particles. The gizzard may be poorly developed, as in scorpions in which it is merely a dilation of the esophagus.

Mid-gut.—The anterior portion of the mid-gut (the thoracenteron) is situated in the cephalothorax. It consists of paired blind tubes with outpocketings (caeca). The thoracenteron wall is built up of two types of cells, absorbing and enzyme-producing. The interstitial tissue between the tubes is poorly developed or



FROM T. I. STORER & R. L. USINGER, "GENERAL ZOOLOGY" (1957); REPRODUCED BY PERMISSION OF MCGRAW-HILL BOOK CO., INC

FIG. 2.—STRUCTURE OF SPIDER AS SEEN WITH LEFT SIDE OF BODY REMOVED

lacking, except in scorpions. The portion of the mid-gut situated in the abdomen consists of a tube with several many-branched tubules that end in sacs (ampullae) held together by interstitial tissue; the whole complex was formerly spoken of as the "liver," but is rather a digestive gland. The walls of this gland are built up of the same type of cells as those of the thoracenteron. The main tube forms the stercoral pouch at its posterior end near the rectum. Excrements are formed in this pouch.

Hind-gut.—The hind-gut consists merely of a very short rectum that opens by means of an anus at the end of the abdomen. An anal covering (operculum) is present in some arachnids but lacking in others.

Living arthropods form the chief food of arachnids; scavengers are known only among mites. Some opilionids feed on snails, and certain mites are the only arachnids that feed on plants.

3. Circulatory System.—Most arachnids have an open circulatory system in which there are no true capillaries and no veins; certain acarids, however, lack any kind of circulatory system. The main cavity of the arachnid body is termed a haemocoele; it consists of expansive blood channels (sinuses) that lie among the tissues and surround all the organs. (A true coelom is represented by segmental coelomic sacs.)

The tubular heart, dorsally situated in the abdomen, pumps blood through the vessels and into the sinuses, where tissues absorb oxygen and food and release carbon dioxide and other waste products. The heart has from two to seven pairs of funnel-shaped valvelike openings (ostia) that allow blood to enter the heart but not leave it through channels other than the anterior aorta and the abdominal arteries. The elongate heart is composed of two layers of muscular fibres, an inner circular and an outer longitudinal one, and is surrounded by a tubular membrane, the pericardium. A large artery (anterior aorta) goes forward into the cephalothorax, then forks, the two branches passing on either side of the gut under the endosternite. At this point they open into a sinus from which arteries supplying the appendages arise. In the abdomen the heart gives off lateral arteries and a posterior artery (caudal aorta) that usually forms three branches. Blood, after circulating, is returned to the heart through the pericardial sinus.

Blood.—There are several types of corpuscles in the colourless circulating blood. The copper-containing respiratory pigment hemocyanin, dissolved in the blood plasma, turns blue upon exposure to air. Clotting is effected by agglutination of blood corpuscles.

4. Respiratory System.—Arachnids respire by means of book lungs, tracheal tubes, or a combination of the two. Each book lung consists of an invaginated pouch located in the anterior portion of the ventral abdomen, and opens to the surface by a thin slit. A series of thin, leaflike plates, through which course very fine blood vessels, are arranged horizontally within each lung. The hollow, thin-walled tracheal tubes are like those found in insects: openings (spiracles) allow air to flow into the larger elastic tubes (tracheae) and from them into the finer branches (tracheoles) that ramify throughout the body. Both types of respiratory organs, in proximity to tissue cells and blood sinuses, effect easy exchange of gases through moist lining membranes.

Four pairs of book lungs, the greatest number known, are found only in scorpions. Schizomids have but a single pair; phrynichids and thelyphonids two pairs. Solpugids, pseudoscorpions, ricinuleids, opiliones and acarids have only tracheal tubes. Spiders show the greatest diversity in the structure of their respiratory system. Some have two pairs of book lungs; others have only a single pair and, in addition, tracheal tubes; and still others only tracheal tubes. The number and position of the tracheal spiracles often varies within the same order but is fixed in others. The solpugids have seven spiracles: the first pair is situated on the cephalothorax between the second and third coxae, the second and third pairs on the third and fourth abdominal sternites and the single seventh spiracle on the fifth sternite. Opiliones have a single pair of spiracles on the second abdominal sternite.

The position of the spiracle also varies among the acarids. In some acarids there are no respiratory organs; oxygen passes di-

rectly through the thin body wall. Among palpigrades certain ventral sacs may have a respiratory function.

5. Excretory System.—Excretion is accomplished by the coxal glands or by Malpighian tubules. The coxal glands are modified nephridia (small, tubular excretory organs of invertebrates) consisting of a blind pouch (sacculus), a more or less convoluted tubule (labyrinth) and one or two outlets to the outside at the base of the coxae. The position of these outlets varies from order to order. One or two pairs of Malpighian tubules are present in most arachnids but are lacking in the opilionids. These tubules open into the gut, at the junction of the hind-gut and mid-gut, and excrete crystals of guanine, the end product of nitrogenous metabolism. These crystals may be excreted through the anus or stored in special cells that form white patterns visible through the skin.

6. Nervous System.—The central nervous system of arachnids is of the same type as that of other arthropods; it consists of a dorsal brain and a ventral chain of paired ganglia, typically one pair for each somite. This original condition is found only in the embryos of scorpions and possibly some other arachnids. In all adult arachnids the ventral chain presents numerous modifications generally consisting of a forward displacement of ganglia and a more or less complete fusion of them in the cephalothorax. The brain is composed of a fore-brain with nerves for the eyes and a hind-brain with nerves for the chelicerae. It is connected with the ventral nerve cord by means of heavy nerves that surround the anterior portion of the digestive tracts. In some arachnids, such as scorpions and thelyphonids, some of the ganglia remain in the abdomen, though rarely in their original place; in others, such as spiders, all abdominal ganglia move into the cephalothorax. The five pairs of thoracic ganglia give off nerves to the thoracic appendages; the second abdominal ganglia, always incorporated in the thoracic mass, give off nerves to the second somite. The sympathetic nervous system (responsible for involuntary functions) is represented by a cardiac nerve and a pair of stomodeal nerves (innervating the fore-gut) originating in the hind-brain.

7. Reproductive System.—Among the arachnids the sexes are always separate, and the genital opening is found on the second abdominal somite in both sexes. This is true of all orders but the acarids. Among the latter the genital openings may be either dorsal or ventral in position, apparently varying with the habits of the various species.

Among scorpions and opilionids the male copulatory organs are connected with the reproductive organs. The copulatory organs of scorpions consist of a pair of ventral outgrowths of the genital operculum; in the opilionids there is a single tubular penis that can be withdrawn into a sheath. The pseudoscorpions have a pair of noncopulatory accessory reproductive structures, the "ram's horns," which are protrusible (see *Mating Behaviour* below).

Neither the ricinuleids nor spiders have male copulatory organs that are directly connected with the reproductive organs. Among the ricinuleids the third pair of legs has a copulatory apparatus, and among the spiders the palpi of the males are modified for the transference of sperm to the female.

When present, the external genitalia of females are on the second abdominal somite. Female opilionids have a long retractile egg-laying structure (ovipositor), and many female spiders have the aforementioned epigynum, a chitinous structure of unknown function that surrounds the genital openings.

In the male two small testes lie below the intestine; each is joined by a coiled tubule to a single seminal vesicle that leads to the genital opening. The female has two large ovaries, also below the intestine, that each join the vagina (the chamber that receives the male copulatory organ) by an oviduct; two seminal receptacles, which join the vagina near the genital opening, store the sperm deposited in the vagina by the male.

IV. REPRODUCTION AND GROWTH

1. Development.—Most arachnids are egg layers (oviparous). Some groups, however, produce living young (are viviparous), and still others produce eggs that are incubated and often hatched within the parent's body (are ovoviviparous). Some mites are parthenogenetic; that is, they are able to produce young from eggs that have not been fertilized by sperm.

The oviparous forms include, among others, spiders, opilionids, thelyphonids and some mites. Many of these forms, such as the spiders, encase their eggs in cocoons that they deposit in small crevices or attach to the web or some other support. Other arachnids simply lay their eggs in a crevice or small hollow in the soil, and some forms carry their eggs about or guard them in a nest.

The viviparous arachnids include some species of scorpions and some acarids. These forms retain the eggs within the oviducts of the females. Among some scorpions, however, the embryo has a tubular extension, somewhat like an umbilical cord, along which nutrient fluids from the intestinal wall of the mother pass to the mouth of the embryo.

A few solpugids and certain acarids are considered to be ovoviviparous. In one solpugid, *Galeodes*, the eggs develop in the ovarian tubes to an advanced stage, then hatch from the eggs within a day or two after being laid.

The young arachnid emerging from the egg resembles the adult, yet shows considerable differences. The freshly hatched ricinuleid or acarid has only six legs—only four among some acarids—and is called a larva. Later stages among the pseudoscorpions are termed nymphs. In other arachnids the shape of the body, the proportions of the appendages and the placement of the eyes are not quite the same as in the adult. Sexes are difficult to distinguish until the later stages. Among some arachnids the young remain with the mother until after the first molt and then disperse.

2. Growth.—The heavy, chitinous exoskeleton, which very effectively protects the arachnid from mechanical injury and drying, must be shed periodically as the animal grows.

Molting.—Molting (ecdysis) occurs at varying intervals during the growth period of arachnids, and the periods of time between molts are known as stadia. When the animal is about to molt, it usually hides in some protected spot. Some spiders spin special webs or sheets upon which they lie while discarding their outgrown exoskeleton. The new exoskeleton is soft and flexible, and all growth in size can occur only during this period directly following the molt. Until the new exoskeleton hardens, the arachnid is quite helpless and is often preyed upon by small insects that it ordinarily could avoid.

The number of molts required to reach maturity varies widely from group to group. Among the scorpions *Palamnaeus longimanus* apparently has eight stadia and *Androctonus australis* seven. The spiders show great variation. Small species molt 4 or 5 times, medium sized ones 7 or 8, and the large tarantulas may molt as many as 22 times before reaching maturity.

Life Span.—Although it seems quite certain that in the temperate areas most arachnids live but a single year, there are species which apparently survive for several years. Whip scorpions, scorpions and solpugids appear to live more than a single year, and some of the large tarantulas have been kept in captivity for as many as 20 years.

V. NATURAL HISTORY

1. Living Habits.—Most arachnids are free-living terrestrial forms. There are, however, exceptions to this generalization: some acarids live in fresh water, others in the sea and some are parasitic. Some species of spiders have become adept at living near water; they are able to run upon the water's surface and dive. One spider, found in Europe and Asia, *Argyroneta aquatica*, builds a tent under water and fills it with air. All arachnids are characterized by the fact that their behaviour, no matter how complex, is instinctive.

The great majority of arachnids lead solitary lives, hunting or waiting for their prey. Apparently the only time they get together is during mating. Even this "socializing" may be for only a brief period, for often the female is larger than the male and will consume him after mating if he does not escape.

Some opilionids, a few acarids and a dozen or so species of spiders are gregarious. In drier areas, such as the southwestern U.S., the opilionids sometimes congregate by the thousands in

FIG. 3.—REPRESENTATIVE ARACHNIDS IN CHARACTERISTIC HABITATS: (NOT DRAWN TO SCALE) JUMPING SPIDER (SALTICUS); BLACK WIDOW SPIDER (LATRODECTUS), TRAP-DOOR SPIDER (BOTHRIOCYRTUM); WHIP SCORPION (MASTIGOPROCTUS); AMERICAN TARANTULA (APHONOPELMA); SCORPION (VEJOVIS); SUN SPIDER (EREMOBATES); WOLF SPIDER (LYCOSA); HARVESTMAN (PHALANGIUM); FALSE SCORPION (APOCHEIRIDIUM); TICK (DERMACENTOR); ORB-WEAVING SPIDER (ARGIOPE)

great masses under roofs, bridges or other protected areas. This behaviour pattern appears to be a method of conserving moisture during dry periods. Those spiders that are gregarious live in large "community" webs.

2. Food-getting.—The manner in which arachnids obtain their food also varies greatly. Scorpions probably do not go out to seek their food, rather they wait in their lairs until suitable prey comes along. The solpugids are predatory and have an extraordinary voracity; the long-legged forms can run at a great speed in search of prey. They have been known to kill not only insects, but even large spiders, scorpions and lizards. Only when they are gorged with food or are pregnant do the solpugids become sluggish. It appears that the pseudoscorpions also wait for their prey to come along. The large American whip scorpion (*Mastigoproctus giganteus*) is nocturnal and moves about slowly and cautiously, touching all objects as it searches for prey. Once an insect is grasped it is carried to the burrow before being eaten. The opilionids feed on fresh or recently dead animal tissue; they also eat a great variety of other materials such as fungi, seeds or even bird droppings.

Spiders show tremendous variation in their food-getting habits: some forms sit quietly beside their webs, waiting for some hapless insect to get entangled, while others actively run over the ground in search of prey.

3. Mating Behaviour.—The most interesting aspect of arachnid behaviour is in their mating habits. In many, a "dance" or "promenade" precedes the actual mating. Among several different groups, including the scorpions, whip scorpions and pseudoscorpions, the male grasps the palpi of the female with his palpi and then walks sidewards or backwards while she follows. The male pseudoscorpion also may display his ram's horn organs in an effort to interest the female.

In many cases the male does not directly transfer the sperm to the female, rather he first deposits the sperm on the ground or on a special web, then transfers it. The male scorpion deposits a capsule of sperm (spermatophore) on the ground, then draws the female over it. She lowers herself over the spermatophore, thereby inserting the capsule in her genital opening. Pseudoscorpions have a similar behaviour. The spider male uses his highly modified palpus as a special intromittent organ for transferring the sperm to the female.

Mating among the solpugids is rapid and seemingly brutal. The male strokes the female until she becomes lethargic. He then grasps her with his chelicerae, palpi and walking legs and lays her on her side. After he expands her genital opening, he emits a mass of sperm which falls to the ground; this he gathers with his chelicerae and forces into the female's genital opening.

The opilionids are more casual in their mating habits. Males and females encounter one another accidentally, mate briefly—the male transferring sperm directly to the female by means of his penis—separate and then wander off. Among the spiders there are often elaborate courtship displays or special signs, such as tweaking the web, by which the often smaller male makes himself known to the larger female.

4. Special Glands and Poisons.—Among the arachnids are many types of specialized glands that often are characteristic of each group. The better known glands are the silk glands of spiders and pseudoscorpions, the poison glands of scorpions and spiders and the repugnatorial (odoriferous) glands of opilionids. Of these, the poison glands of the scorpions and spiders are probably the most notorious.

Poison Glands.—The poison glands of the scorpion are found in the enlarged base of the sting at the end of the tail. Two types of poisons are recognized as being produced by different scorpions. One of these poisons is local in effect and harmless for man; the other attacks the nervous system (is neurotoxic) and is extremely toxic for man. In the United States the scorpion *Centruroides vittatus* is harmless, but *C. sculpturatus* and *C. gertschi* are very poisonous. The symptoms of poisoning appear rapidly and are characterized by a feeling of tightness in the throat. Death may follow if treatment with antivenom is not instituted soon after the person is stung.

The poison glands of spiders are associated with the chelicerae, as mentioned earlier. It may be in the basal segment of the chelicera or may extend farther back into the head region. The poison, released from a tiny opening at the end of the fang, is in most cases quite harmless for man; at most it causes only momentary discomfort. A few spiders of the genus *Latrodectus*, however, produce a poison which is considered very virulent. Fortunately, however, the amount injected is usually so small that death has occurred in only about 5% of the known cases of persons bitten. The black widow spider (*Latrodectus mactans*) of North America is the most notorious of this genus. Its bite may induce in the person bitten profuse sweating, difficulty in breathing, vomiting and prostration. Although the illness may seem grave, rarely is it fatal.

Some spiders of the genus *Loxosceles* likewise have the reputation of being dangerous. The bite of *Loxosceles reclusus*, found in the midwestern and southern U.S., results in a severe local reaction that may be followed by more general symptoms. *Loxosceles laeta* of South America is also regarded as dangerous.

Silk-Producing Glands.—Among the arachnids spiders are best known for their ability to spin webs from silk produced in glands within their bodies. They are not alone in this ability, for pseudoscorpions and some mites too can spin silk, but to a much lesser extent.

The silk of the pseudoscorpion is derived from glands in the cephalothorax whose ducts traverse the chelicerae to the tip of the movable finger. The spinning is actually done by the chelicerae. Pseudoscorpions use this silk chiefly for the construction of nests in which they may molt or hibernate and for the weaving of cocoons for their eggs. Nest-building is carried out in this manner: the silk is drawn out in several very fine, sticky threads, the spinning being accompanied by forward and backward movements of the body as well as by lateral movements of the chelicerae. The animal works until it is gradually imprisoned by a dense covering.

Spider silk has its origin from the special silk glands located in the mid-ventral portion of the abdomen. At least seven different types of silk glands are known, each of which produces a different type of silk having a special function. The spinnerets, through which the glands open, are located at the end of the abdomen. The tiny spinning tubes, located on the spinnerets, average about 100 in number.

Spiders have many uses for their silk. Whenever they move about, they spin a dragline or securing thread, by means of which they can drop rapidly if threatened. Far more complex are the webs that are used as snares for unwary insects. The spider also utilizes its silk for cocoons for its eggs, for the construction of retreats in which to molt, for webs on which to deposit the sperm when the male charges his palpus and for the lining of burrows. The threads are usually not single fibres but actually strands from

several glands. A few mites also have silk glands. The spider mites ("red spiders") of the family Tetranychidae cover the leaves of trees with silken webs that serve as protective coverings for their eggs and young.

Repugnatorial Glands.—These glands occur chiefly in opilionids and thelyphonids. In most cases they secrete a fluid that because of its odour repels possible predators. The odoriferous glands of the opilionids are found in both sexes of all species. They are located near the anterior margin of the cephalothorax, opposite the attachment of the first pair of legs. The glands themselves often can be seen through the carapace, and their openings are on the surface of the cephalothorax, above the coxa of the second leg. In some species the glandular secretion can be discharged to a distance of more than an inch, but in most forms it simply flows from the gland opening. Among the tropical and subtropical members of the suborder Laniatores, the secretion is bright yellow or reddish brown, highly volatile and has an acrid smell. Some of the large opilionids of the family Gonyleptidae from Brazil produce a strong nauseating odour when handled. The opilionids of temperate areas have a colourless fluid with no detectable odour for man.

In the southern United States, whip scorpions (thelyphonids) are known locally as vinegarroon because of the vinegarlike aerosol secretion which they exude from the anal region when annoyed. This secretion is not poisonous but probably serves to repel threatening predators.

5. Beliefs Concerning Arachnids.—Arachnids very often are disliked by people, not for any rational reason, but because they crawl, run, hide or have predaceous habits. Many are regarded as being poisonous, when actually few are. Possibly because arachnids are common and abundant, they have long been the subjects of many interesting stories in folklore.

The opilionids, for example, are sometimes called shepherd spiders because it was once believed that fields heavily infested with them were good sheep pasture. An old Essex superstition says that it is unlucky to kill a harvestman because of the belief that these animals helped farmers reap their fields; the harvestmen's long legs brought to mind the scythe, rake and sickle.

Some unfounded stories maintain that scorpions can commit suicide by stinging themselves when surrounded by a ring of fire.

Spiders, of course, have many legends associated with them. Among their virtues are supposedly industry, patience and persistence. In parts of the United States it is believed that killing a harvestman or spider will bring rain.

VI. FOSSIL ARACHNIDS

The earliest known fossil arachnids are scorpions found in the Silurian (from about 320,000,000 to 350,000,000 years ago). It was supposed for a long time that they were marine. The American *Proscorpius osborni* was found in limestone strata of New York together with the extinct scorpionlike marine eurypterids. But the structure of both the European *Palaeophonus* and the American *Proscorpius* is so typical of the order Scorpiones that it is more probable that the fossil scorpions led a terrestrial rather than an aquatic life. They may have lived, however, near water. Excellently preserved remnants of arachnids belonging to the orders Trigonotarbi, Araneae and Acari are found in later strata, the Devonian Red Sandstone of Scotland. Apparently all orders of Arachnida were represented in the succeeding Carboniferous period, though Palpigradi have been described as fossils only from the still later Jurassic of Europe and Schizomida from the late Cenozoic era (the present to about 70,000,000 years ago) of Arizona.

The Mesozoic era (from about 70,000,000 to 200,000,000 years ago) left practically no fossil records of Arachnida. On the other hand the Cenozoic era is rich in fossil Arachnida. Those found in Baltic amber and in the Tertiary shale of Colorado possess all the characters of recent Arachnida. It is reasonable to assume that Arachnida as a group distinct from other Arthropoda must have appeared in the early Paleozoic era (about 500,000,000 years ago).

The larval or immature forms of the horseshoe crab (*Limulus*) resemble the ancient trilobites so closely that they were termed trilobite larvae. According to some authorities, this relationship indicates that the ancient trilobites were ancestral to present-day arachnids. The eurypterids, also closely related to the horseshoe crabs, were abundant during the Paleozoic. These forms bore a strong superficial resemblance to present-day scorpions. *See* also EURYPTERIDA; TRILOBITE.

VII. IMPORTANCE TO MAN

Inasmuch as so many of the arachnids have secretive or nocturnal habits and are most abundant in the tropical and subtropical areas of the world, their economic importance may often be underestimated. Certainly any group of predators that occurs in as great numbers as arachnids, can and does exert quite an influence on the insect population of any habitat. Spiders in particular can attain enormous numbers; for example, an estimate of some 14,000 individuals on shrubs and herbs on an acre of woodland in the midwestern U.S. may be quite modest.

The solpugids are known to have voracious appetites. A young *Galeodes* species was observed to devour over 100 flies in 24 hours. One small nocturnal species, *Eremobates pallipes*, from Colorado is reputed to hunt bedbugs; and it has been said that a predaceous crab spider *Thanatus flavidus* effectively controlled an outbreak of bedbugs in Athens, Greece, during 1923–24.

Of the arachnids the mites and ticks are the more directly important to man. Tiny mites occur in such numbers in soil that it is certain that they play a role in the gradual change of leaves and other organic debris to humus. Ticks are better known, for most of them can be readily seen and they are pests of man and his domestic animals.

Tick-borne rickettsial diseases are common in many parts of the world. In the United States, Rocky mountain spotted fever is transmitted by the wood tick *Dermacentor andersoni* in the northwestern states and by other ticks in other regions (*see* ROCKY MOUNTAIN SPOTTED FEVER AND OTHER SPOTTED FEVERS; RICKETTSIAE). In the southern states, most people have been bothered by chiggers (*q.v.*), which are actually the larvae of chigger mites (family Trombiculidae). Fruit growers know the spider mites and dog owners are well acquainted with the itch and mange mites (Acaridae, Psoroptidae and Sarcoptidae). Many mites infest stored grains and copra. People dwelling in overcrowded areas frequently are infested with itch mites.

VIII. CLASSIFICATION

The following classification of the Arachnida is the one generally recognized by most students of the class. In it are described four subclasses with their 16 orders, 11 of which are living and 5

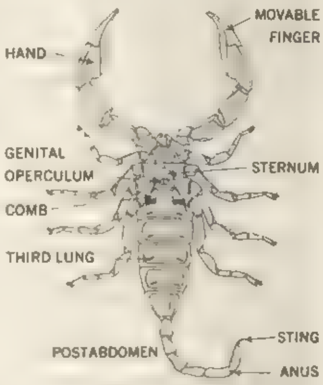
(preceded by †) wholly extinct.

A. Subclass Latigastra

Arachnida in which the abdomen is broadly joined to the cephalothorax.

Superorder Pectinifera.—With a pair of abdominal appendages on the third somite.

1. Order Scorpiones (Scorpions).—(Fig. 5) Carapace entire, with a pair of median and from three to five pairs of lateral eyes. Abdomen segmented, subdivided into a preabdomen of seven segments and a postabdomen of five segments, the so-called tail ending in a sting. First abdominal somite disappears during development, original number of 12 segments restored by subsegmentation. Preabdominal tergites and sternites separated by intersegmental membranes and lateral pleurae. Postabdominal segments annular. Chelicerae pincerlike (chelate), three-jointed. Pedipalpi powerful, chelate, with rudimentary processes called gnathobases. First and second coxae with gnathobases bearing maxillary glands. Abdominal appendages modified as combs, situated immediately behind the covering of the genital opening. Four pairs of book lungs on third to sixth preabdominal sternites. Heart in the preabdomen, with seven pairs of ostia. Size from 14 to 180 mm. Ovoviviparous. Six recent and five fossil families. Earliest fossil records from the Silurian. Several hundred species now living mostly in tropics, several species in southern Europe and in the U.S.



FROM A. PETRUNKEVITCH IN "TRANSACTIONS OF THE CONNECTICUT ACADEMY OF ARTS & SCIENCES"

FIG. 5.—SCORPION (OPISTHACANTHUS LEPTURUS), OF THE ORDER SCORPIONES; VENTRAL VIEW

Superorder Epectinata.—Without abdominal appendages.

a. Branch Chelata.—Abdomen clearly segmented, with 12 tergites and sternites.

2. Order Pseudoscorpiones (False or Book Scorpions).—(Fig. 6) Carapace entire, with one or two pairs of eyes. First to tenth abdominal tergites and fourth to tenth sternites often subdivided into a right and left sclerite. Twelfth segment small, rudimentary. Chelicerae chelate, two-jointed, their movable finger with a spinneret (galea). Pedipalpi powerful, chelate, with a poison gland opening on the immobile finger. All coxae meet in median line, movable. Legs with an additional joint called trochantin or basifemur, between trochanter and femur. Patella fused with tibia. Tarsus one-jointed, ending in two claws with an arolium. Lungs lacking. Two pairs of tracheal spiracles on third and fourth abdominal sternites. Heart with three or four pairs of ostia. Central nervous system concentrated in the cephalothorax. Males with ram's horn organs used for excitation of female in mating. Females with a brood pouch for eggs. Size from 0.8 to 6 mm. Oviparous. Three suborders: (1) suborder Chthoniinea with two families; (2) suborder Neobisiinea with nine families; (3) suborder Cheliferinea with six families and about 300 species. Common book scorpion, *Chelifer cancroides*, found in homes and libraries all over the world. Many species blind.

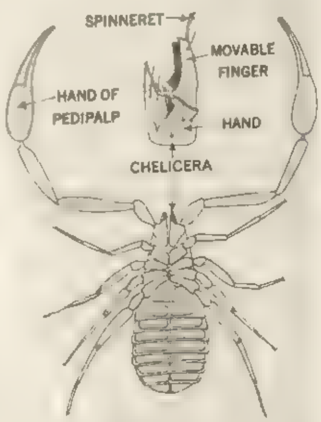


FIG. 6.—COMMON BOOK SCORPION (CHELIFER CANCROIDES), OF THE ORDER PSEUDOSCORPIONES; VENTRAL VIEW. DETAIL OF THE CHELICERA AT TOP

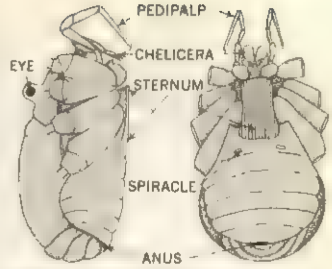
Majority live on the ground, in vegetal detritus, under bark, etc. Some species are found in caves. Species of *Garypus* are found on algae along the seashore. *Neobisium maritimum* of England and France lives between low and high tide lines.

b. Branch Jugata.—Abdomen either partially or completely fused with cephalothorax.

3. Order Opiliones (Harvestmen, Daddy Longlegs).—(Fig. 7) From three to eight abdominal tergites fused with carapace, remainder free. A single pair of eyes, usually on a median tubercle. Chelicerae chelate, three-jointed. Pedipalpi leglike or raptorial. Walking legs usually long and slender, in some species 20 times longer than body, typically seven-jointed, but tarsus often subdivided. First and second tarsi with a single claw, third and fourth with one or two claws. Arrangement of coxae variable. All coxae movable in Phalangiidae and some other groups; all immobile in Nemastomatidae and Trogulidae; first pair movable, the rest coalesced and immobile in Laniatores. Lungs lacking. Single pair of tracheal spiracles on second abdominal sternite. Heart with two pairs of ostia. Nervous system highly concentrated. Males with a penis, females with an ovipositor. Pharynx hexagonal, without sieve, making ingestion of coarse particles possible. Gizzard lacking. Size from 1 to 22 mm. Oviparous. More than 3,000 species distributed among three suborders: (1) Suborder Cyphophthalmi. A single abdominal segment free. One family Sironidae. (2) Suborder Laniatores (=Mecostethi). Not more than five abdominal tergites fused with carapace. Pedipalpi raptorial. Third and fourth tarsi with two claws. Six families: Oncopodidae, Phalangiidae, Assamiidae, Cosmetidae, Gonyleptidae and Triaenonychidae. (3) Suborder Palpatores (=Plagiostethi). Pedipalpi leglike. All tarsi with a single claw. Five families: Trogulidae, Nemastomatidae, Acropsopilionidae, Ischyropsalidae and Phalangiidae.



ALEXANDER PETRUNKEVITCH

FIG. 7.—DADDY LONGLEGS (LIOBUNUM LONGIPES), OF THE ORDER OPILIONES: (LEFT) LATERAL VIEW; (RIGHT) VENTRAL VIEW OF BODY WITH ENDS OF LEGS CUT OFF

4. Order Acari (Mites and Ticks).—(Fig. 8) Abdomen usually more or less fused with cephalothorax, rarely segmented. Body often subdivided into a head region (gnathosoma or capitulum) and a body proper, the latter dorsally further subdivided by a groove between second and third legs into a propodosoma and a metapodosoma. Mouthparts adapted to piercing, sucking, biting, grating or sawing and correspondingly modified, often completely withdrawn into a special anterior cavity, the camerostome. Arrangement of coxae variable, characteristic of whole suborders. Four pairs of legs except in Tetrapodili which have only two pairs. Gizzard lacking. Salivary glands often present. Anus ventral or lacking. Respiration by tracheal tubes, or, in absence of such directly through the skin and gut. Position of tracheal spiracles and their number characteristic for different suborders. Lungs lacking. Heart with one or two pairs of ostia or completely lacking. Male genital opening variable in position, ventral, posterior or dorsal, with or without a penis. Female genital opening also variable in position, usually ventral, in Acaridae dorsal. Size from 0.1 to 30 mm. Oviparous, a few species ovoviviparous. Development with a six-legged larva, four-legged in Tetrapodili. Many thousands of species distributed among 167 families in six suborders; (1) Suborder Notostigmata. Abdomen (opisthosoma) clearly segmented with four pairs of dorsal tracheal spiracles on anterior four segments. All coxae freely movable. A single family Opilioacaridae. (2) Suborder Holothyroidea. Highly chitinized body without visible segmentation. Two pairs of spiracles above third and fourth coxae. All coxae freely movable. Genital opening in both sexes ventral, between third and fourth coxae. A single family Holothyridae. (3) Suborder Parasitiformes. Capitulum well developed. One pair of spiracles behind second, third or fourth coxae. Coxae either freely movable or immobile. Male genital opening ventral, variable in position. Female genital opening ventral, between second and third coxae. Superfamily Mesostigmata with 27 families and superfamily Ixodides with two families, Ixodidae and Argasidae. To these two families belong all the ticks. (4) Suborder Trombidiformes. Traces of segmentation often present. One pair of spiracles behind the mouthparts, or absent. Coxae immobile, incorporated in the body wall. Anus and heart lacking. Male genital opening variable in position, ventral, posterior or dorsal, with or without a penis. Superfamily Tarsonemini with four families. To this superfamily belongs the remarkable louse mite *Pediculoides ventricosus*. Superfamily Stomatostigmata with seven families. Superfamily Prostigmata with 59 families, among them the Tetranychidae or spider mites ("red spiders"), the Demodicidae or follicle mites, the Trombiculidae or chigger mites, the Hadrachnidae or water mites and the Halacaridae or marine mites. (5) Suborder Sarcoptiformes. Coxae immobile, incorporated in the body wall. Propodosoma clearly defined. Mouthparts in a camerostome. Four pairs of spiracles in the soft membrane between the body wall and the trochanters, or spiracles lacking. Heart absent. Male genital opening posterior, with a penis. Female genital opening dorsal, above anus. Superfamily Acaridiae with 37 families, among them Tyroglyphidae or cheese mites, Acaridae or acarid mites, Psoroptidae or scab mites, Sarcoptidae or itch mites. (The last three families are important mites causing dermatitis in man and other animals.) Superfamily Oribatei with 26 families, among them Ori-

batidae or beetle mites. (6) Suborder Tetrapodili or gall mites. Only two pairs of legs. Body often with false segmentation. Coxae immobile, incorporated in the body wall. Tracheae and heart absent. Male genital opening ventral, with penis. Female genital opening also ventral, the opening in both sexes anterior in position. Vegetation-eaters. Larva with two pairs of legs. Two families, Eriophiidae and Phyllocophidae.

c. Branch Corrugata.—Several anterior abdominal tergites considerably shorter than the rest.

†5. Order Architarbi (= Phalangiotarbi).—Fossil Arachnida with segmented abdomen having from 8 to 11 tergites, the anterior 5 or 6 considerably abbreviated. Sternites often subdivided into three longitudinal fields. Carapace entire, with from two to six eyes. All coxae movable, without gnathobases. Chelicerae chelate. Pedipalpi leglike. Walking legs normal. Four families—Architarbidae, Heterotarbidae, Opiliotarbidae and Phalangiotarbidae. Upper Carboniferous of Europe and Pennsylvanian of North America.

B. Subclass Stethostomata

Arachnida with abdomen broadly joined to the cephalothorax, but with the basal joint of chelicerae wedged in between the coxae of the pedipalpi and the mouth and situated ventrally behind the latter.

†1. Order Haptopoda.—(Fig. 9) Fossil Arachnida with carapace entire, with a pair of eyes. Abdomen composed of 11 segments, not counting the anal covering. Genital sternite very large. Chelicerae three-jointed, chelate. Pedipalpi leglike. All tarsi segmented. A single species, *Plesiosiro madeleyi*, from the Upper Carboniferous, England.

FIG. 11.—(LEFT) PALPIGRADE (KOENENIA), OF THE ORDER PALPIGRADI, VENTRAL VIEW. LEGS CUT OFF AT THE TROCHANTERS, FLAGELLUM AT ABOUT A QUARTER OF ITS TOTAL LENGTH. (RIGHT) SCHIZOMID (SCHIZOMUS), OF THE ORDER SCHIZOMIDA; VENTRAL VIEW SHOWING ONLY COXAE AND ANTERIOR THREE ABDOMINAL SEGMENTS

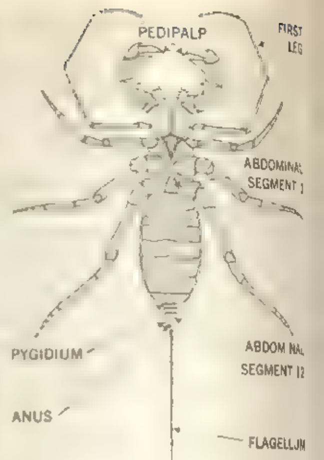
†1. Order Trigonotarbi.—(Fig. 10) Fossil Arachnida with carapace entire, with or without eyes. Abdomen either broadly joined to the carapace or else the juncture is considerably narrowed. Chelicerae two-jointed, retrovert. Pedipalpi leglike. Sternum and underlip and arrangement of coxae as in spiders. Family Palaeocharinidae known only from the Devonian of Scotland. Four families represented by several species in the Upper Carboniferous of Europe and Pennsylvanian of North America.

D. Subclass Caulogastra

Arachnida with attenuated first abdominal somite narrowly joined to the cephalothorax.

Superorder Sternifera.—A sternum composed of a single or more sternites present between the coxae.

1. Order Palpigradi (Palpigrades).—(Fig. 11, left) Carapace subdivided into a propeltidium, mesopeltidium and metapeltidium. Eyes absent. Pedipalpal and first pedal sternites fused into a single plate which is followed by three separate sternites. All coxae movable, without gnathobases. Chelicerae chelate, 3-jointed. Pedipalpi leglike, 9-jointed. First pair of legs 12-jointed, second and third 7-jointed, fourth 8-jointed. Abdomen composed of 11 segments, the last three small, annular, forming a process called the pygidium. Telson a multisegmented flagellum. Book lungs and tracheae lacking. Fourth to sixth sternites each with a pair of ventral sacs capable of turning inside out and supposedly having a respiratory function. Heart in the abdomen, with five pairs of ostia. An abdominal ganglionic mass present in the second abdominal somite. Size 0.6 to 2.8 mm. Presumably oviparous. One recent family, Koeneniidae, and one fossil Mesozoic family, Sternarthronidae.



FROM A. PETRUNKEVITCH IN "TRANSACTIONS OF THE CONNECTICUT ACADEMY OF ARTS AND SCIENCES"

FIG. 12.—WHIP SCORPION (MASTIGOPROCTUS GIGANTEUS), OF THE ORDER THELYPHONIDA; VENTRAL VIEW. CHELICERAE ARE NOT VISIBLE IN THIS POSITION

2. Order Schizomida (Schizomids).— (Fig. 11, right) Carapace subdivided into a propeltidium, mesopeltidium and metapeltidium. Median eyes absent, lateral eyes present or absent. Three thoracic sternites. All coxae movable, without gnathobases. Chelicerae chelate, two-jointed. Pedipalpi raptorial. First tarsus eight-jointed. Abdomen composed of 12 segments, the last three small, annular, forming a pygidium. Telson short, one- or three-jointed. Ventral sacs lacking. A single pair of book lungs, on second abdominal sternite. Heart in the abdomen, with five pairs of ostia. An abdominal ganglionic mass composed of the 5th to 12th ganglia, present in the second abdominal segment. Size from 5 to 7 mm. Oviparous. One recent family, Schizomidae, and one fossil Cenozoic family, Calcitronidae.

3. Order Thelyphonida (Whip Scorpions).—(Fig. 12) Carapace entire, with one pair of median and three pairs of lateral eyes. Three thoracic sternites. All coxae movable, without gnathobases. Chelicerae two-jointed retrovert. Pedipalpi raptorial. First tarsus tactile, nine-jointed. Abdomen composed of 12 segments, the last three small, annular, forming a pygidium. Telson long, whiplike, multijointed. Ventral sacs lacking. Two pairs of book lungs, on second and third abdominal sternites. Heart with nine pairs of ostia, first and second pair in the cephalothorax, third to ninth in the abdomen. Anterior seven abdominal ganglia incorporated in the thoracic ganglionic mass, 8th to 12th ganglia form an abdominal ganglionic mass in the 8th and 9th segments. Size from 25 to 70 mm. Oviparous. A single family, Thelyphonidae.

†4. Order Kustarachnae.—Fossil Arachnida with coxae radiating from an apparently very small sternum. Carapace entire, with a pair of eyes on a median tubercle. Chelicerae not known. Pedipalpi chelate, their coxae fused, forming a single plate. Coxae without gnathobases. Legs thin and long. Abdomen with from seven to ten sternites. Tergites not preserved. A single family, Kustarachnidae, from the Pennsylvanian of North America.

5. Order Phrynichida (Tailless Whip Scorpions).—(Fig. 13) Carapace entire, with a pair of median and three pairs of lateral eyes. Three thoracic sternites. All coxae movable, without gnathobases. Chelicerae two-jointed, retrovert. Pedipalpi raptorial. First tarsus tactile, multijointed. Abdomen composed of 12 segments, the last one forming a pygidium. Two pairs of lungs, on second and third abdominal sternites. One pair of ventral sacs on third abdominal sternite. Heart in the abdomen, with six pairs of ostia. Nervous system concentrated in the cephalothorax. Size from 8 to 45 mm. Oviparous. A single family, Tarantulidae.

FIG. 13.—TAILLESS WHIP SCORPION (TARANTULA FUSCIMANA), OF THE ORDER PHRYNICHIDA; VENTRAL VIEW. BOTH PEDIPALPS AND CHELICERAE ARE SHOWN; ONLY FIRST AND FOURTH LEGS ARE SHOWN

6. Order Araneae (Spiders).—(Fig. 14) Carapace entire, with a pair of median and three pairs of variously arranged lateral eyes. Number of eyes often reduced to two or three pairs, in some cases a single pair or none. Chelicerae two-jointed, retrovert, with ducts of poison glands, except in two fami-

lies. Pedipalpi leglike, in adult males with copulatory apparatus on terminal joint. Pedipalpal coxae with gnathobases bearing maxillary glands. Pedal coxae movable, without gnathobases. Legs seven-jointed. Abdomen entire, except in Liphistiomorphae in which it is composed of 12 visible segments. Abdominal appendages present on fourth and fifth somites and modified as spinnerets. Respiration by means of book lungs or tracheal tubes, or a combination of both, with lung slits and spiracles always on second and third abdominal somites. Heart in the abdomen, with from two to five pairs of ostia. Nervous system concentrated in the cephalothorax. Size from 1 to 75 mm. Oviparous. Nearly 3,000 genera with many thousands of species. Sixty-four recent and seven fossil families distributed among five suborders: (1) Suborder Liphistiomorphae. Spiders with segmented abdomen, chelicerae in the same axis as the body (paraxial), two pairs of lungs, eight spinnerets and four or five pairs of cardiac ostia. Two recent and two fossil families. (2) Suborder Mygalomorphae. Spiders with abdomen entire, paraxial chelicerae; two pairs of lungs; four, rarely two or six, spinnerets; and three or four pairs of cardiac ostia. Eight families including the trap-door spiders and tarantulas. (3) Suborder Hypochilomorphae. Spiders with abdomen entire, chelicerae directed slightly outward (diaxial), two pairs of lungs, six spinnerets and a flattened vestige of the appendage of the fourth somite (cribellum) and four pairs of cardiac ostia. A single family Hypochilidae. (4) Suborder Dipneumonomorphae. Spiders with abdomen entire, chelicerae diaxial, one pair of lungs and one pair of (or a single) tracheal spiracles, six spinnerets with or without a cribellum, sometimes only two or four spinnerets without cribellum, two or three pairs of cardiac ostia. Forty-nine recent and five fossil families including among them the Argiopidae or geometric orb weavers, Theridiidae or reticular web weavers, Thomisidae or crab spiders, Salticidae or jumping spiders. (5) Suborder Apneumonomorphae. Spiders with abdomen entire, chelicerae diaxial, lungs absent, one or two pairs of tracheal spiracles, six spinnerets without cribellum, two pairs of cardiac ostia. Four families.

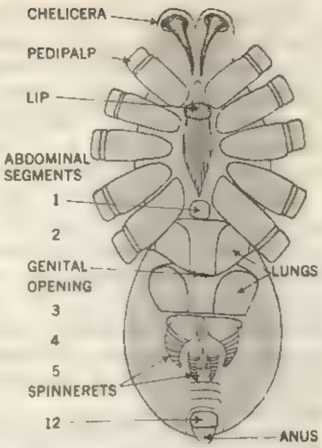

FIG. 14.—SPIDER (LIPHISTIUS MALAYANUS), OF THE ORDER ARANEAE: VENTRAL VIEW. OF THE PEDIPALPS AND LEGS, ONLY THE COXAE AND TROCHANTERS ARE SHOWN

Superorder Cucullifera.—A movable plate, the cucullus, present, attached to the anterior edge of the carapace. Thoracic sternite concealed, rudimentary.

7. Order Ricinulei (Ricinuleids).—(Fig. 15) Carapace entire, without eyes, always with a cucullus. Abdomen composed of nine segments, the last three small, annular, forming a pygidium which is telescoped in recent species. Two anterior abdominal segments concealed from view by carapace. Chelicerae two-jointed, chelate. Pedipalpi chelate. Coxae, except fourth pair, immobile. First and second trochanters single-jointed; third and fourth two-jointed in recent species. First tarsus one-jointed, second five-jointed, third four-jointed, fourth five-jointed. Lungs absent. One pair of tracheal spiracles above third coxae. Third metatarsus and tarsus modified in mature males as organs of copulation. Size from 4 to 10 mm. Oviparous. Development with a six-legged larva. One recent family Ricinoididae (= Cryptostemmidae) and two fossil families, Polyocheridae and Curculioididae (= Holotergidae).

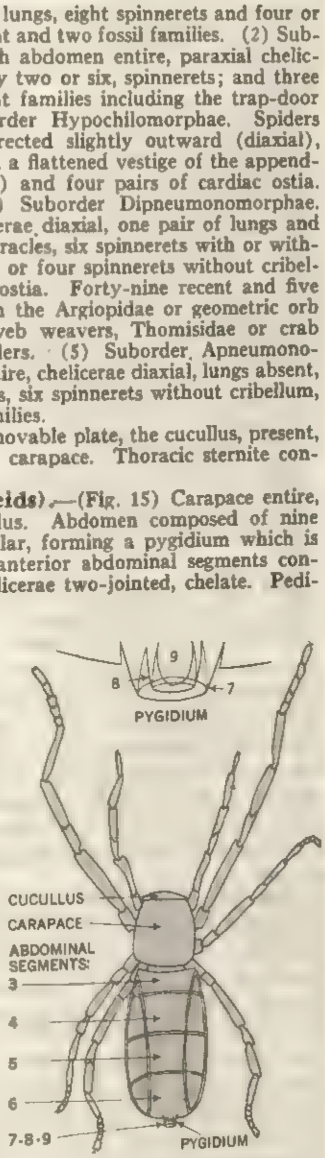

FIG. 15.—RICINULEID CRYPTOCELLUS DOROTHEAE, OF THE ORDER RICINULEI; VENTRAL VIEW. ABDOMINAL SEGMENTS 1 AND 2 CONCEALED BY CARAPACE. DETAIL OF PYGIDIUM AT TOP

Superorder Malleolifera.—Fourth coxa and trochanter with racket organs, or malleoli. Thoracic sternites lacking. Carapace segmented.

8. Order Solifugae (Solpugids, or Sun Spiders).—(Fig. 16) Carapace proper or propeltidium includes only head and first thoracic somite. This is followed by independent tergites representing individual thoracic somites, and by mesopeltidium and metapeltidium. One pair of median and one or two pairs of rudimentary lateral eyes on the propeltidium. Chelicerae powerful, two-jointed, chelate, with movable finger ventral. Pedipalpi tactile. First leg seven-jointed, second seven- or eight-jointed, third and fourth nine-jointed. Abdomen composed of 10 or 11 segments with soft intersegmental and lateral membranes. Seven tracheal spiracles: first pair between second and third coxae, second pair on third abdominal sternite, third pair on fourth abdominal sternite, seventh single median spiracle on fifth sternite. Lungs absent. Heart with eight pairs of ostia, first and second pairs of which are in the cephalothorax, third to eighth pairs in the abdomen. Anterior five abdominal ganglia incorporated in thoracic ganglionic mass, posterior five forming an abdominal ganglionic mass in the sixth segment. Mouth at end of a beak. Size from 10 to 50 mm. Oviparous. Some 200 species distributed among 10 families.

For the different kinds of arachnids *see* separate articles; *e.g.,* MITE; SCORPION; SPIDER; TICK; WHIP SCORPION; and BLACK WIDOW; DADDY LONGLEGS; TARANTULA. *See* also references under "Arachnida" in the Index.

ARACHOSIA (Persian HARAUVATISH or HARAHUVATISH), a province of the Persian, Seleucid and Parthian empires, which took its name from the Arachotas branch of the Etymandrus river, the modern Arghandab. It occupied southern Afghanistan and was bounded on the south by Gedrosia (Baluchistan). The capital city, Alexandria-of-the-Arachosians, founded by Alexander the Great and usually identified as Kandahar, is placed at Ghazni by W. W. Tarn. The Arachosians appear among the tributary nations depicted on the Achaemenid reliefs at Persepolis; their gifts include a Bactrian camel. Darius I obtained ivory from Arachosia and Darius III elephants. (J. M. M.-R.)

ARAD, a town in western Rumania, capital of the Arad district in the Banat region, lies on the north bank of the Mureş river near the Hungarian border. It consists of an inner town and five suburbs. The population in 1956 was 106,412, about one-third Magyar. Arad is a modern town and the seat of a Greek-Orthodox bishop and has a theological seminary, teachers training schools, a conservatoire of music, state theatre and puppet theatre, a museum of art and history, and philharmonic and folk orchestras. In the museum are relics of the Hungarian revolution of 1848–49, and one of the public squares contains a martyrs' monu-

ment commemorating the 13 Hungarian generals shot there by order of the Austrian general J. J. Haynau on Oct. 6, 1849.

Arad is an important railway junction and the largest industrial and commercial centre of western Rumania. Its principal industries are distilling, milling, the manufacture of textiles, machine tools and railway cars, leather-working and saw-milling. A large trade is carried on in grain, flour, alcohol, cattle and timber. An air service links Arad with Bucharest.

Arad, a fortress conquered by the Turks in 1551 and rebuilt by them three years later, was lost to the Austrians in 1685. It was captured by the Hungarians on July 1, 1849, and was their headquarters during the latter part of the insurrection. There Lajos Kossuth (*q.v.*) issued his famous proclamation, and handed over his supreme military and civil power to Arthur Görgei. The fortress was recaptured shortly after Görgei's capitulation at Világos. Arad became Rumanian after World War I.

The town of Aradul Nou (New Arad) on the opposite bank of the Mureş is practically a suburb of Arad, with which it is connected by a bridge.

ARADUS (modern ARWAD or RUAD), the Greek name for the Hebrew ARVAD, an ancient Phoenician city situated on a small rocky island of the same name less than 2 mi. off the Syrian coast halfway between Latakia and Tripoli (Tarabulus al-Sham). The island, with a circumference of one mile, still shows remains of the Phoenician walls on the eastern side. Strabo (xvi, 2, 13) attributed the founding of the city to the Sidonians, and Eusebius thought that the city was founded in 761 B.C., but the name appears in near eastern texts in the 2nd millennium. The Old Testament lists the Arvadites as the sons of Canaan (Gen. x, 18); they are mentioned in the Ugaritic tablets as *'rwdn*. Aradus, which resisted conquest by Thutmose III in the 15th century B.C. but succumbed to superior force, is often mentioned in Egyptian sources. The Amarna letters of the 14th century state that Aradus (Arwada) allied itself with Sidon and Beirut against Rib-Addi of Byblos. Later the Hittites gained control of the city; Aradus was on the side of the Hittites at the battle of Kadesh (1288 B.C.). Aradus paid tribute to the Assyrian kings Tiglath-pileser I (reigned 1116–1076) and Ashurnasirpal II (reigned 884–859), who received gold, silver, tin, copper, linen garments, monkeys, ebony, boxwood and ivory from the Phoenician coastal areas, including Aradus; the city must therefore have had a flourishing trade with Africa. Matinu-ba'lu of Aradus provided 200 soldiers for the Aramaean coalition against Shalmaneser III at the battle of Karkar (853). A king with the same name paid tribute to Tiglath-pileser III (reigned 745–727), and both Sennacherib and Esarhaddon received tribute from the city. Ashurbanipal forced Iakinlu of Aradus to submit to his yoke, and the king brought his daughter to Nineveh with a dowry to do menial service. In the Persian empire Aradus with its mainland counterpart Tartus (Antaradus) was the capital of a province extending from Latakia to the Eleutherus river (Nahr al-Kebir) and to the borders of Hamath to the east. Ships of Aradus were in Xerxes I's fleet in his attack on Greece (480 B.C.). The province of Aradus was handed over to Alexander the Great in 332 B.C. without a struggle.

(J. S. I.)

ARAFURA SEA, a shallow continental shelf sea, lies between Australia and New Guinea. It includes technically the great bight of the Gulf of Carpentaria and extends eastward as far as Cape York, the extreme northern tip of Queensland and Australia. It is generally under 100 fathoms; the maximum depth, south of the Tanimbar Islands, is 642 fathoms. The entrance from Torres strait is notoriously dangerous, and the Arafura sea probably contains numerous uncharted shoals; currents are variable except during the southeast monsoon. (O. H. K. S.)

ARAGO, (DOMINIQUE) FRANÇOIS (JEAN) (1786–1853), French physicist who discovered the principle of the development of magnetism by rotation, was born on Feb. 26, 1786, at Estagel, Roussillon, and died in Paris on Oct. 2, 1853. He was educated in Perpignan and at the École Polytechnique, Paris.

He joined J. B. Biot in 1806 to complete the measurement of an arc of the meridian. At the age of 23 he succeeded J. J. L. de Lalande in the chair of analytical geometry at the École Polytechnique and became one of the astronomers at the observatory. In 1830 he entered politics as a republican deputy, advocating measures for the advancement of science and for technical developments, and was appointed director of the observatory and permanent secretary of the Academy of Sciences. As minister of war and marine in the provisional government formed after the revolution of 1848, he introduced many reforms.

Arago's original scientific work was mainly concerned with electromagnetism and the wave theory of light. Following up the work of H. C. Oersted, he showed in 1820 that a cylindrical spiral of copper wire through which an electric current was flowing attracted iron filings as if it were a magnet, but that the filings fell off when the current ceased; he showed also (1824) that a rotating copper disk produced rotation in a magnetic needle suspended above it. These effects were later shown by Michael Faraday to be due to induction.

His researches on light were closely linked with those of A. J. Fresnel, E. L. Malus and Thomas Young, who were shaping the wave theory of light at the beginning of the 19th century. Fresnel's arguments were not accepted by Laplace, S. D. Poisson and Biot, who favoured the emission theory, but they were strongly supported by F. H. A. Humboldt and by Arago, who had been appointed by the Academy of Sciences to report on Fresnel's work. As a result Fresnel and Arago joined in further researches which led to the enunciation of the fundamental laws of the polarization of light.

Arago's many studies on the wave theory included his crucial experiment for comparing directly the velocity of light in air and in water or glass. According to the emission theory, the velocity should be accelerated as light passed from a rarer into a denser medium; according to the wave theory, it should be retarded. In 1838 he described his apparatus, which employed the revolving mirrors used by Sir Charles Wheatstone in 1835 for measuring the velocity of the electric discharge; but, because of the great care required in the experiment, as well as the interruptions of the revolution of 1848, Arago was not ready until the spring of 1850, and then his eyesight suddenly failed. Before his death, however, the retardation of light in denser media was experimentally demonstrated by A. H. L. Fizeau and J. B. L. Foucault by his method with improvements in detail.

Arago's writings were published in 17 volumes in 1854–62. He was elected a foreign member of the Royal Society of London in 1818 and became in 1825 the first Frenchman to receive its Copley medal. (D. McK.)

ARAGON was a constituent kingdom of the Spanish monarchy. Historically, "Aragon" is an ambiguous term. Strictly, it refers only to the political entity which, at the close of the middle ages, was comprised within the area of the three modern Spanish provinces of Huesca, Saragossa and Teruel. But the kings of Aragon were also rulers of the constitutionally separate county of Barcelona (Catalonia), the kingdom of Valencia and various oversea territories in the Mediterranean. Moreover the kingdom of Aragon proper was inferior to Catalonia and Valencia in political, economic and cultural importance. Despite this, all the peninsular possessions of the Aragonese crown are frequently referred to as Aragon.

The original kingdom was brought into existence by a testimentary act of Sancho III of Navarre in 1035. Sancho left to his third son, Ramiro, the then small Pyrenean county of Aragon, elevating it to be an independent kingdom. To this mountain domain (which took its name from the river flowing through Jaca, its capital) Ramiro (1035–63) was soon able to add the counties of Sobrarbe and Ribagorza, to the east of it. All the counties had long been under Frankish influence, which had an important bearing on the character of some Aragonese institutions. By 1104 the kings of Aragon had doubled the size of the original kingdom by conquests southward toward the Ebro. Saragossa, capital of the important Almoravid kingdom of the same name, fell to Alfonso I of Aragon (1104–34) in 1118, and the occupation of the valleys of the Jalón and Júcar rivers, to the south of Saragossa and the Ebro, soon followed. These conquests, involving the absorption into Aragon of large numbers of Mudéjar and Mozarab farm-

ers and artisans, greatly altered the social complexion of the country. The pattern of future operations against the Moors was fixed by the treaty of Cazorla, signed by Alfonso II of Aragon (1162–96) and Alfonso VIII of Castile in 1179, which divided those parts of Spain remaining in Muslim hands into two zones—one for each kingdom to reconquer.

In 1150 the ruler of Catalonia, Ramón Berenguer IV, count of Barcelona, married the heiress of the kingdom of Aragon. Thus, until 1410, both countries came to be ruled by the Catalan house of Barcelona. The previous history of Catalonia, formerly the Frankish-dominated Spanish March, had been unlike that of Aragon (*see* BARCELONA, COUNTS OF). It possessed a unified legal code (in which feudal custom played a large part) and a written political constitution and was much more cosmopolitan and bourgeois in outlook than Aragon. Until 1412 Catalan influence dominated the union, with the Catalans tending to support the crown in its frequent constitutional struggles with the feudal Aragonese nobility. The union was of great value to the Catalans, who were able to devote themselves to commerce and maritime expansion, knowing that the financial and military responsibility of defending them from Castile would fall largely on the inhabitants of the Aragonese hinterland. Navarre, ruled by Aragon since 1076, became independent again in 1134; it once more came under the crown of Aragon in the reign of John II (king of Aragon from 1458 to 1479 and of Navarre from 1425).

At the time of their union, both Aragon and Catalonia had developed important territorial interests in southern France. These occupied much of the attention of the crown until Aragonese pretensions in France were finally abandoned in 1258. The only territory north of the Pyrenees that remained permanently attached to the Aragonese crown was the county of Roussillon (*q.v.*). The occupation of the Balearic Islands (*q.v.*) took place in 1228 and the conquest of the rich Moorish kingdom of Valencia (*q.v.*) in 1238. Valencia, like the Balearics, was colonized by Catalans, though it retained a large Mudéjar population. It was administered as a separate kingdom of the crown of Aragon, with its own laws and parliament. Having thus completed the occupation of the Moorish territories allotted to Aragon by the treaty of Cazorla, the Aragonese began expansion in the Mediterranean, made possible by the seapower of the Catalans. In 1282, after the Sicilian Vespers, Peter III (1276–85) was received by the Sicilians as their king, and thenceforward Sicily was ruled either directly by the kings of Aragon or by their relatives. Sardinia was incorporated in the Aragonese empire in 1320. A further accretion to Aragonese power came in 1442, when Alfonso V (1416–58) successfully concluded his long struggle to conquer the kingdom of Naples (*q.v.*).

Between 1356 and 1369 Peter IV (1336–87) had been involved in a disastrous war with Castile. This war and its aftermath revealed that the powerful feudal nobles of Aragon tended to sympathize more with the Castilian magnates than with their own municipalist dynasty. Their chance came in 1412 when, after the extinction of the house of Barcelona in 1410, they procured the election of a Castilian prince, Ferdinand of Trastámara, to the vacant throne against strong Catalan opposition. The final blow to Catalan supremacy came when Alfonso V of Aragon transferred his capital to Naples in 1443, though, later, the Catalans waged an unsuccessful civil war against Trastámaran rule. John II countered this resistance by arranging for his heir, Ferdinand, to marry Isabella, heiress of Henry IV of Castile. In 1479, therefore, on John's death, the countries of the Aragonese crown were united with Castile.

Under this union the Aragonese countries retained their own political and administrative systems (for details *see* SPAIN: *History*), despite certain modifications under Philip II, until the beginning of the 18th century, when, in consequence of the rebellion of the lands of the crown of Aragon during the War of the Spanish Succession, their constitutional privileges were abrogated by Philip V. As an administrative unit the old kingdom of Aragon proper survived until 1833, when the division of it into the three existing provinces took place.

See H. J. Chaytor, *A History of Aragon and Catalonia* (1933); Andrés Jiménez Soler, *La edad media en la corona de Aragón*, 2nd ed. (1944). (P. E. R.)

ARAGONITE, one of the five known forms of calcium carbonate ($CaCO_3$), was named for its first-known occurrence in Aragon province, Spain. Together with calcite and vaterite, it occurs as a mineral in nature. The other two forms, calcite II and calcite III, are found only in the laboratory under pressures of the order of 20,000 atm. at room temperature. Calcite is the commonest natural form of calcium carbonate, while aragonite is second. Vaterite is comparatively rare.

Aragonite crystallizes in the orthorhombic system and is colourless, white or yellowish, transparent to translucent, with a vitreous lustre, and thus resembles calcite. It may be easily distinguished from calcite, however, by its lack of any pronounced cleavage and by its greater hardness (3.5 to 4) and specific gravity (2.94). All forms are soluble with effervescence in hydrochloric acid.

Aragonite may be manufactured in the laboratory from calcite by the application of approximately 7,000 atm. pressure while heating at 350° C.; at higher temperatures more pressure is required. On the other hand, under atmospheric pressure aragonite converts rapidly to calcite at about 425° C. Aragonite may be easily prepared by the reaction of calcium chloride ($CaCl_2$) with sodium carbonate (Na_2CO_3) at about 90° C., using solutions of high concentration. Lower temperatures produce mixtures of calcite and aragonite. At room temperature vaterite may be produced.

There are no known natural occurrences of aragonite in which it has formed in its own stability field, hence it (together presumably with vaterite) is unstable with respect to calcite under natural conditions; therefore it must with geological time eventually be transformed to calcite, even in the absence of high temperatures. Calcite and aragonite were among the earliest recognized examples of polymorphism (the ability of one chemical substance to exist in two or more crystalline forms).

Aragonite is found all over the world. It occurs in near-surface, low-temperature deposits primarily as sinter or evaporation deposits from hot springs or in caves as stalactites. The skeletal remains of many invertebrates both fossil and recent consist of aragonite. *See* also CALCITE. (J. C. JN.)

ARAGUA, one of the smaller states of Venezuela with a short coastline on the Caribbean. Area 2,708 sq.mi.; pop. (1961) 312,274. The central highlands there are composed of two ranges, separated by an intermontane basin, in which Lake Valencia lies. The climate is tropical and, though there is considerable rain inland, the coast is dry. The state lies in Venezuela's most important political and agricultural region, with the densest rural population. The capital, Maracay (*q.v.*), is situated in the fertile Aragua valley, 1,500 ft. above sea level and 77 mi. S.W. of Caracas. It was by gaining possession of the fine fattening pastures around Lake Valencia that Juan Vicente Gómez, dictator and one-time cattle rustler, cornered Venezuela's cattle industry (*see* VENEZUELA: *History*), and Maracay became the centre of his far-flung cattle operations.

The Aragua valley produces a variety of agricultural products; although sugar cane has for many years ranked first, the acreage in such food crops as beans, maize and rice increases steadily, as does that of cotton. Aragua is one of the country's most diversified states, both agriculturally and industrially. The famous and extensive 210,000-ac. Parque Nacional Rancho Grande occupies the entire northern half of Aragua. Probably no Venezuelan state is so well served by hard surface roads.

Several small towns of importance are La Victoria, Cagua, Turmero and Villa de Cura. Puerto Ocumare handles a modest trade by sea. (L. WE.)

ARAGUAIA, a river of Brazil rising at about 18° S., and 53° W., on the *Planalto Central*. In its upper part it forms the boundary between Mato Grosso and Goiás. It flows north northeast for a distance estimated at 1,366 mi. to its junction with the Tocantins (*q.v.*) a little south of 5° S. In its middle course this river divides into two channels on either side of the island of Bananal, which is about 250 mi. long. The *braço maior*, or major arm, is interrupted by many falls and rapids; the *braço menor*, the

smaller eastern channel, can be used for navigation by small boats. A major tributary of the Araguaia is the Rio das Mortes, which rises near Cuiabá. The river drains a vast area of interior Brazil in which there are few people and which has yet to be carefully mapped. As a line of travel the river is poor, for it is frequently interrupted by falls. Downstream from Bananal Island there are two major falls, one dropping 85 ft. in 18 mi., the other 50 ft. in 12 mi. For short stretches, however, it is navigable for small river boats. The river was explored in part in 1897 by Henri Coudreau, who wrote *Voyage au Tocantins-Araguaya.* (P. E. J.)

ARAK, the chief town of the former province of that name in Iran, has, since 1938, been incorporated into Gilan the First *ostan* (province). Pop. (1956) 58,929 mainly of Persian stock with some admixture of Turks and Armenians. It lies 5,750 ft. above sea level at the entrance of an important mountain gap giving access to the inner valleys of the southwestern Iranian ranges. The gap is used by the Trans-Iranian railway and by a metalled road connecting Qom (Qum) to Kermanshah, Khorramabad (Khurramabad) and Dezful. The climate is cold in winter but agreeable in summer. The adjoining plain of Farahan is dotted with many villages, all irrigated, the surplus waters being dissipated in the central salt pan of Tuzlu Gol (Namak-e Mighan). Vines, fruits, melons and cereals are the main crops, supplies being increased by the produce of the mountain valleys, which includes sugar beet. Arak is the marketing centre of the district and has a sugar refinery. It is also known for its carpets and rugs.

The town was formerly named Sultanabad. It was founded in 1808 by a local dignitary and laid out on a regular grid plan. The former capital of the province was Saruq, 28 mi. N.W. (H. Bo.)

ARAKAN, a natural region and an administrative division of Burma. The former comprises a strip along the eastern coast of the Bay of Bengal from the Naf estuary on the border of Chittagong (in East Pakistan) to Cape Negrais, and is about 400 mi. long and 90 mi. wide at its broadest in the north. The southernmost 100 mi. of the region is in the Irrawaddy division. The chief of many islands bordering the coast are Cheduba, Ramree and Shahpura. The principal rivers are the Naf estuary; the Mayu, an arm of the sea running almost parallel with the coast for about 50 mi.; the Kaladan, rising near the Blue mountain in the extreme northeast and falling into the sea south of the Mayu, and navigable for 40 mi. by vessels up to 400 tons; and the Lemro, which enters the sea south of the Kaladan. Farther south the nearness of the boundary range of the Arakan Yoma shortens the rivers; the Dalet and An are navigable by boats; of the Sandoway, Taungup and Gwa, the last affords harbourage for small vessels. The easiest of several passes over the Arakan mountains are the An route to Ngape and Minbu in central Burma, and the Taungup route to Padaung on the Irrawaddy. The latter route is now an all-weather motor road; previously the main access to Arakan was by sea. Air services link Sandoway and Rangoon.

The three districts of Arakan division are Akyab, Kyaukpyu and Sandoway (*qq.v.*) (formerly Ramree), and its headquarters is at Akyab. Before Burma's independence (1948) it included the wild, forested northern Arakan Hill Tracts, now in the Chin Hills Special division (*q.v.*). Its area was then 16,000 sq.mi. The population at the time of the British initial occupation did not exceed 100,000; by 1941 it had risen to 1,186,738. Only one-tenth of this very hilly division is cultivated and rice occupies nine-tenths of the cropped areas. Other crops include fruits, chillies, dhani and tobacco. The natural vegetation of the lower slopes (up to 3,000 ft.) is evergreen forest, in most areas too wet for teak; that of the higher slopes is evergreen oaks. The forests have however been destroyed over huge areas by *taung-ya* (shifting cultivation) and their place taken by a useless tangle of bamboo.

The Arakanese are Burmans, but separated from the parent stock by the Arakan Yoma. Like the Burmans, they are Buddhists, but have a dialect and customs of their own. They trace their history back to 2666 B.C., with a lineal succession of 227 princes, and claim that their empire once extended over Ava and part of China and Bengal, though known facts of history do not corroborate this claim. The Moguls and Pegus invaded the country at different times, and the Portuguese gained a temporary foothold in Arakan. But in 1782 the Burmans conquered the province, and it was ceded to the British in 1826. The former capital, Arakan (now called Myohaung, "old city"), is on a small branch of the Kaladan, 50 mi. N.E. of Akyab. Its remoteness from harbours and extreme unhealthiness led to its decay, and Akyab became the chief town. (L. D. S.)

ARAKCHEEV, ALEKSEI ANDREEVICH, COUNT (1769–1834), Russian army officer and statesman noted for his stern discipline, was born near Bezhetsk, Tver province, on Oct. 4 (new style; Sept. 23, old style), 1769, of an old Novgorod family. So impressive was his reorganization of the army corps maintained by tsarevitch Pavel Petrovich at Gatchina that, upon the tsarevitch's accession to the throne as Paul I, Arakcheev was entrusted with the reorganization of the whole army. He introduced many important reforms, including vital hygienic measures, but the sternness of his discipline alienated the officers' corps and he was dismissed in 1798 and, after a brief reinstatement, again in 1799.

In 1803, under Alexander I, Arakcheev became inspector-general of the artillery. His wise reorganization of the whole department contributed greatly to the victories of the Russians during the Napoleonic wars. With the discovery of commissariat scandals, the services of an incorruptible disciplinarian were especially valued, and Arakcheev was appointed inspector-general and war minister (1808). When, on the outbreak of the Swedish war of 1809, the emperor ordered the army across the ice of the Gulf of Finland, it was only the presence of Arakcheev that compelled an unwilling general and a semimutinous army to begin a campaign which ended in the conquest of Finland. On the institution of the imperial council, Arakcheev was made a member of the council of ministers and a senator (1810), while still retaining the war office. Although he took no active part in the war of 1812, all the correspondence and dispatches relating to it passed through his hands, and he was the emperor's inseparable companion during the whole course of it. In Alexander's last years Arakcheev was his chief counselor and friend, to whom he submitted all his projects for consideration and revision. On the accession of Nicholas I, Arakcheev, broken in health, restricted his immense sphere of activity and, in April 1826, resigned all his offices and retired to Carlsbad. His last days he spent on his estate at Gruzina, carefully collecting all his memorials of Alexander. He died there on May 3 (N.S., April 21, O.S.), 1834.

See V. Ratch, *Svedeniia o grafe A. A. Arakcheeve* ("Information About Count A. A. Arakcheev") (1864); M. I. Semevski, *Graf Arakcheev i voennye poseleniya* ("Count Arakcheev and the Military Colonies") (1871). (G. A. Ln.)

ARALIA, a genus of aromatic herbs, shrubs and small trees of the aralia or ginseng family (Araliaceae), containing about 35 species, in North America, Asia, Malaya and Australia. Some are cultivated for ornamental foliage and some possess medicinal properties. The stems and leaf stalks are often spiny or bristly; the leaves are usually much divided into toothed leaflets; and the small flowers, which are borne in panicled umbels, are sometimes very numerous, the entire inflorescence being showy. Among the North American members of the genus are the American spikenard (*Aralia racemosa*), which grows from three feet to six feet high in rich woods from New Brunswick to South Dakota and south to Georgia and Missouri; the wild sarsaparilla (*A. nudicaulis*), a foot in height, found in woods from Newfoundland to British Columbia, south to North Carolina and Colorado; the bristly sarsaparilla (*A. hispida*), about two feet high, native to sandy clearings from Newfoundland to Hudson bay and southward to North Carolina and Indiana; the elk clover (*A. californica*), a robust form, sometimes ten feet high, found along mountain streams in California. The angelica tree, Hercules'-club or devil's-walking-stick (*A. spinosa*) is a spiny shrub or small tree, sometimes 40 ft. high, native to low grounds from Delaware to Indiana and southward to Florida and Texas, frequently planted for ornament and sometimes escaping to roadsides and thickets. The Chinese angelica tree (*A. sinensis*) and the Japanese angelica tree (*A. elata*) are the east Asian counterparts of the North American *A. spinosa*, but less

prickly and with more showy flowers. Many hardy varieties of the Chinese angelica tree are in cultivation. Numerous greenhouse plants called aralias are species of *Polyscias*, *Schefflera* and related genera of the aralia family. Ginseng (*q.v.*) is obtained from *Panax schinseng*, native to China, and from the American *P. quinquefolius*, plants closely related to the aralias.

The American spikenard (*A. racemosa*) and the related *A. nudicaulis* and *A. spinosa* contain in their roots or rootstocks a mucilaginous compound yielding calcium oxalate, used as an alterative. (N. Tr.)

ARAL SEA (Aralskoye More), a lake or inland sea in Soviet western Asia, lies between latitude 43° 30′ and 46° 50′ N., and longitude 58° 0′ and 62° E., in the Kazakh S.S.R., the Uzbek S.S.R. and the Kara-Kalpak Autonomous S.S.R., about 175 mi. E. of the Caspian sea. It was known to the ancient Arab and Persian geographers as the Sea of Kharezm, from the neighbouring district of the Chorasmians, and derives its present name from the Kirghiz designation of Araldenghiz, or Sea of Islands. It is the fourth largest inland sea in the world, having an area of 25,659 sq.mi. and a total length of 266 mi. and a width of 176 mi. The maximum depth is 223 ft., in a depression parallel to the west coast, and the average is 65 to 80 ft. Its altitude is 241 ft. above the Caspian, *i.e.*, 164 ft. above sea level. It is surrounded on the north by steppes; on the west by the rocky plateau of Ustyurt, separating it from the Caspian; on the south by the alluvial district of Khiva; and on the east by the Kyzylkum (*q.v.*) desert. The northern shores are low, and broken by irregular bays such as those of Sary-chaganak and Paskevicha. On the west an almost unbroken wall of clay formation extends from Chernyshëva bay southward, and attains a height of about 250 ft.

On the south is the delta of the Amu-Dar'ya (*q.v.*), one of the arms of which forms a swamp, 80 mi. long and 10 mi. broad, before it discharges into the sea. The Syr-Dar'ya (*q.v.*) enters in the northeast. These rivers bring down vast quantities of sediment; the delta of the Syr-Dar'ya increased by about 13 sq.mi. between 1847 and 1900, but because of the increased demands of irrigation the flow of water from both rivers greatly decreased. The eastern coast is fringed with multitudes of small islands, and others, some of considerable size, lie in the open toward north and west. Frequency and violence of storms, and almost total absence of shelter hinder navigation; shipping is confined to seven months in the year. The northeast wind is the most prevalent, and sometimes blows for months together. The salinity of Aral is a low 10.7‰, but salinification is proceeding. The surface temperature varies between 32° F. in winter, when long stretches of the coast are ice-fringed, and 80° in late summer. Variations of level are remarkable and irregular.

Within historic times the Aral sea may have had a connection with the Mertvyy Kultuk gulf (Zaliv Komsomolets) of the northeast Caspian, and in this case would then have been a fresh-water lake. Its level was much higher in post-Pliocene times, for shells of Pecten and Mytilus species occur in the Kara-Kum desert 34 mi. to the south of, and 80 ft. or perhaps even 213 ft. above, the present sea. Between the 13th and 16th centuries and in antiquity the Amu-Dar'ya may have sent an arm to the Caspian south of the Ustyurt plateau. Until 1880 the sea had long been diminishing and this gave rise to the idea, in western Europe, that the inland basins of west central Asia were drying up, but from 1880 to 1908 the level rose by nearly 10 ft., and there was increased utilization of the waters of Amu-Dar'ya and Syr-Dar'ya in their upper courses for irrigation. Islands previously linked with the shore became widely separated from it.

The fish of Aral are fresh-water species and some of its rapid streams still preserve the ancient fish type *Scaphirhynchus*. Fishing is not so productive as in the Caspian but is considerable, the most common types being carp, barbel and sturgeon. Aralsk and Muinak are the centres of the industry. (G. E. Wr.)

ARAM, EUGENE (1704–1759), English scholar and murderer, was born at Ramsgill, Yorkshire. In 1745, when he was schoolmaster at Knaresborough, a man named Daniel Clark, his intimate friend, after obtaining a considerable quantity of goods from tradesmen, disappeared. Suspicions of being concerned in this swindling transaction fell upon Aram. His garden was searched, and some of the goods found there. As, however, there was not evidence sufficient to convict him of any crime, he was discharged. For several years he traveled through parts of England, acting as usher in a number of schools, and settled finally at Lynn, in Norfolk. During his travels he had amassed considerable material for a projected *Comparative Lexicon of the English, Latin, Greek, Hebrew and Celtic Languages.* He was undoubtedly an original philologist, who realized, what was then not yet admitted by scholars, the affinity of the Celtic language to the other languages of Europe, and could dispute the then accepted belief that Latin was derived from Greek. But he was not destined to live in history as the pioneer of a new philology. In Feb. 1758 a skeleton was dug up at Knaresborough, and some suspicion arose that it might be Clark's. Aram's wife had more than once hinted that her husband and a man named Houseman knew the secret of Clark's disappearance. Houseman was at once arrested and confronted with the bones that had been found. After denials, he confessed that he had been present at the murder of Clark by Aram and another man, Terry, of whom nothing further was heard. He also gave information as to the place where the body had been buried in St. Robert's Cave, a well-known spot near Knaresborough. A skeleton was dug up here, and Aram was immediately arrested, and sent to York for trial. He was found guilty, and condemned to be executed on Aug. 6, 1759. While in his cell he confessed his guilt, and asserted that he had discovered a criminal intimacy between Clark and his own wife.

His story has been romanticized in verse by Thomas Hood ("The Dream of Eugene Aram") and in prose by Bulwer Lytton (*Eugene Aram*). Reports of the trial are in (Borrow's) *Celebrated Crimes*, the *Newgate Calendar, Tyburn Chronicle* and similar publications. The best study is E. R. Watson, *Eugene Aram* (1913).

ARAMAEANS, a confederacy of tribes speaking a North Semitic language which, between the 11th and 8th centuries B.C., occupied Aram, a region comprising a large area of northern Syria. In the same period some of these tribes, migrating to the east and southeast, seized large tracts of Mesopotamia.

Sources for the history and language of the Aramaeans are (1) archaic Aramaic inscriptions from northern Syria going back to the 10th or to the 11th century B.C.; (2) references in contemporary Assyrian records; and (3) references in the Old Testament.

History.—In the Old Testament traditions exemplified in the national pedigrees (Gen. xi, 28 ff.) and in the tale of Jacob and Laban (Gen. xxxi, 17 ff.) the Aramaeans are represented as being closely akin to the Hebrews and as having been resident in northern Syria around Harran from patriarchal times; *i.e.*, perhaps the 16th century B.C. Though these traditions are regarded by many scholars as anachronistic, the original home of the Aramaic-speaking tribes may well have been where Old Testament tradition places it, namely in the Syrian desert (Qedem, "the east"; Gen. xxix, 1). It can be assumed that these tribes followed the normal pattern of many other nomad Bedouins who, welling out of the desert, settled in adjacent agricultural lands and mingled with other peoples there. The Aramaeans are often mentioned in Assyrian records as freebooters jointly with another people called Akhlame. The Akhlame are first mentioned in a letter of *c.* 1375 B.C. found at Tall al Amarna in which they are said to be on the Euphrates river. About 50 years later they had reached the upper Tigris, but were repulsed by the Assyrians. In the 13th century B.C. they were attacked by the Assyrians on the Khabur river and on the middle Euphrates, where they are later found settled. The first mention of the Aramaeans is made by Tiglath-pileser I, king of Assyria from 1116 to 1076, who claims to have launched 28 campaigns against them and the Akhlame on a front from Tadmor (Palmyra) to Anat and Rapiqu on the middle Euphrates. By the end of the 11th century B.C. the Aramaeans had formed the state of Bit-Adini on both sides of the Euphrates below Carchemish. In the Khabur valley they formed the sheikhdoms of Laqe, Bit-Bahiani (Tall Halaf) and Bit-Halupe. The Temanai tribe seized Nasibina (Nisibis), Huzirina and Gidara, southwest of Mardin (in Turkish Kurdistan), the northernmost point that they reached being Suru in the Tur 'Abdin hills. West of the

Euphrates, they penetrated to the Amanus mountains and settled at Sam'al (Zincirli). The centre was held by the sheikhdom of Bit-Agusi, with Arpad (*q.v.*) for capital, and Hamath also fell to them. Farther south, the Anti-Lebanon area was divided between the sheikhdom of Zobah in the Beqa' (perhaps forming one with Bit-Rehob on the Litani river), Maacah and Geshur east of Galilee, and Damascus. About 1030 B.C. a coalition of these southern Aramaeans, led by Hadadezer, king of Zobah and in league with the Ammonites, with the Edomites and with the Aramaeans of Mesopotamia, pressed hard on Israel, but was defeated by David in three campaigns. All of Syria is said then to have done homage to David. David's son Solomon (reigned *c.* 973–936) also claimed supremacy over the same area with the exception of Bit-Adini and seems to have occupied Tadmor (Palmyra), but Damascus, under Rezon, appears to have freed itself. Rezon's successors Bar-Hadad I (Hebrew, Ben-Hadad; throne name, Hadadezer; Akkadian, Adad-idri) and Bar-Hadad II (Hadadezer in Assyrian records) renewed the struggle, but Bar-Hadad II was defeated by Ahab, king of Israel (*c.* 875–*c.* 852), who made peace with him.

Ahab's clemency to Bar-Hadad was due to his anxiety over a worse threat, the aggressiveness of Assyria. During the 11th century the Aramaean tribes had not merely occupied Syria; they had also spread along the middle and lower Euphrates, along the middle Tigris and farther eastward into Babylonia, where an Aramaean usurper was crowned king of Babylon under the name of Adad-apal-iddin. By the 9th century the whole area from Babylon to the sea was in the hands of the Aramaean tribes known collectively as Kaldu (or Kashdu)—the biblical Chaldeans. Assyria was thus nearly encircled, but Ashurnasirpal II of Assyria (reigned 884–859) took the offensive against the Aramaeans and received the submission of Bit-Bahiani on the west. Shalmaneser III of Assyria annexed Bit-Adini in 856 and in 853 fought a battle at Karkar against the army of Hamath, Aram, Phoenicia and Israel. This battle was indecisive, but in 838 Shalmaneser was able to annex the area held by the tribes on the middle Euphrates.

Between Israel and Damascus, wars and uneasy pacts alternated for a century after Ahab's time. Then Tiglath-pileser III of Assyria captured Arpad, the centre of Aramaean resistance in northern Syria, in 740 B.C., overthrew Samaria in 734 and Damascus in 732. Finally the destruction of Hamath by Sargon II of Assyria in 720 marked the end of the Aramaean kingdoms of the west.

Aramaeans on the lower Tigris maintained their independence longer. A Chaldean, Merodach-baladan, ruled Babylon from about 722 to 710 and withstood Assyrian attacks. In the bitter struggle after his death the Assyrians deported 208,000 Aramaeans and even in 689 B.C. razed Babylon. Yet the Aramaeans were undaunted; Babylon was rebuilt and the struggle was soon renewed. In 626 a Chaldean general, Nabopolassar, proclaimed himself king of Babylon and joined with the Medes and Scythians to overthrow Assyria. In the New Babylonian or "Chaldean" empire, Chaldeans, Aramaeans and Babylonians became largely indistinguishable. (*See* BABYLONIA AND ASSYRIA: *History.*)

Script and Language.—Aramaic is a Semitic language closest to Hebrew and Phoenician but bearing some points of similarity to Arabic. It used the Phoenician alphabet; the earliest example is of the 10th–9th century B.C. on an altar from Tall Halaf. There are many examples from Syria from the 9th to the 8th century, by which time Aramaic was used for religious and state purposes. These inscriptions show signs that Aramaic was already becoming a literary language. By the 8th century it had developed into dialects, but a general form was widely spoken among the educated (*cf.* II Kings xviii, 26–28 where, in the Authorized Version, it is called, as sometimes elsewhere, "the Syrian tongue") and was accepted by the Assyrians themselves almost as a second official language. Mass deportations of people by the Assyrians and the use of Aramaic as a *lingua franca* by Babylonian merchants served to spread the language. By the neo-Babylonian period it was in general use in Mesopotamia. Under the Persian empire (539–332 B.C.) "imperial Aramaic" was officially employed from Egypt to India. After the conquests of Alexander the Great, Greek displaced it as the official language of the east throughout the former Persian empire, but Aramaic dialects survived into Roman times, their scripts developing local forms such as Palmyrene, Nabataean, Samaritan and Syriac. Certain portions of the Old Testament, *e.g.*, in Daniel and Ezra, are in Aramaic. The Babylonian Talmud was written largely in one Aramaic dialect, the Jerusalem Talmud in another. In Palestine, Aramaic continued as the current speech of the people, Hebrew being that of religion and state and the upper class. Aramaic was the language of Jesus and of the apostles, and Aramaic translations (Targums) circulated with the Hebrew Bible. Apart from its preservation in daily life into modern times in a few isolated villages near Damascus and in southeastern Turkey, in the Tur 'Abdin hills, and on the east bank of Lake Urmia (Azerbaijan province, Iran) it has continued in use among the East Syrian Christians till modern times. It is still recited in parts of the Jewish liturgy. (*See* SEMITIC LANGUAGES.)

Culture.—It is scarcely possible to disentangle a specifically Aramaic culture from the relatively few works of art and objects discovered by archaeology. The Aramaean princes, notably those of Bit-Bahiani and of Sam'al, patronized a provincial form of Syrian art under strong Hittite or Mitannian influence. These Aramaeans evidently wore the local dress of those peoples. Assyrian artists, however, depict Aramaeans on frescoes at Til-Barsip as Bedouin, and on their sculptures they show the Aramaeans of Mesopotamia wearing a short kilt and bearded, with a headband, the women wearing long draperies.

Religion.—Though their pantheon included Canaanite, Babylonian and Assyrian gods, the Aramaeans had deities of their own. Their chief god was Hadad, or Ramman (in the Old Testament Rimmon), equated with the Hurrian storm god, Teshub. His chief temple was at Damascus. Their chief goddess was Atargatis (Atar'ate), a fusion of two deities corresponding to the Phoenician Astarte and Anath. Her chief shrine was at Hierapolis in Syria. They also worshiped the Babylonian Sin, god of the moon; Nabu, god of wisdom; Shamash, the sun god; the Canaanite El, father of the gods; Reshef, god of war and lightning; and many others. There is some evidence that Yau, *i.e.*, Yahweh, was included in the gods worshiped by the Aramaeans at Hamath.

ARAMAIC LANGUAGES: *see* SEMITIC LANGUAGES.

ARANDA, PEDRO PABLO ABARCA DE BOLEA, CONDE DE (1718–1798), Spanish statesman and general, who typified the spirit of enlightened despotism in the government of Charles III, was born at Siétamo, in Aragon, on Dec. 18, 1718. Under Ferdinand VI he was director-general of artillery and introduced the Prussian system of drill into the Spanish army, which he commanded during the Portuguese campaign of 1762. He was appointed captain general of Valencia in March 1764, and later of Aragon.

Aranda's political career began in 1766 when riots in Madrid forced Charles III to dismiss his unpopular Italian minister, Leopoldo de Squillace. Aranda was then made president of the council of Castile. As an aristocrat, soldier and moderate reformer, Aranda was useful to Charles III in restoring the order and confidence shaken by his early reforms. Imperious in character and contemptuous of those who opposed him, Aranda valued only his own opinions, yet he was the efficient executor of the royal will rather than the author of a policy himself. His devotion to absolute monarchy and his religious views were both revealed when he prepared and, in April 1767, executed the royal decree expelling the Jesuits on the pretext that they had instigated the riots of the previous year. His partiality for reform and new ideas was accompanied by enthusiasm for contemporary French thought, but in spite of his skepticism, his sympathy for *Encyclopédiste* ideas and his association with Spanish freemasonry, of which he was grand master, he remained nominally a Catholic and felt that it would be dangerous to undermine the Inquisition. Aranda's

contempt for the lawyers and officials whom Charles III chose as ministers made him a difficult colleague and, being held responsible for Spain's failure to eject England from the Falkland Islands, he was dismissed in 1773 and appointed ambassador to France, where he remained until 1787. A revolutionary report on the future of the Spanish colonies, alleged to have been written in 1783 for the advice of Charles III, cannot be regarded as the work of Aranda, though many historians have accepted it as such.

Aranda returned to office under Charles IV and was first minister for a short time in 1792, when he relaxed the official Spanish attitude toward the French Revolution and revoked the stringent press laws. In Nov. 1792 he was replaced by the queen's favourite, Godoy. After the French invasion of Spain in 1794, Aranda objected violently in the council of state to Godoy's policy of continuing the war with France. Godoy then obtained a royal order dismissing Aranda from the council and exiling him to Jaén. In 1795 Charles IV allowed him to retire to his estates in Aragon and he died at Epila on Jan. 9, 1798.

See R. Konetzke, *Die Politik des Grafen Aranda* (1929); A. P. Whitaker, "The Pseudo-Aranda Memoir of 1783," *Hispanic American Historical Review*, vol. xvii, pp. 287–313 (1937). (Jo. L.)

ARAN ISLANDS (ARAINN), three islands in Ireland covering 18.1 sq.mi., part of County Galway, lie between the rocky coast of Connemara and the Burren limestone coast of Clare to the south. Facing the open Atlantic on the west and Galway bay to the east, the islands are made up of horizontal sheets of Carboniferous limestones like the Burren of Clare. The largest, Inishmore (Aranmore or Aran-na-naomh), has the only pier at Kilronan, a village of 231 people with a fine technical school; on the two smaller islands to the southeast, Inisheer (Inis Thiar) and Inishmaan (Inis Mheadhóin), the steamer from Galway cannot land and all passengers and cargo are landed on the shore by currach. The total population (1961) was 1,648 of whom 358 were on Inisheer and 357 on Inishmaan. The people are Irish-speaking and preserve some traditional clothing made from homespun tweeds with shoes (pampooties) of hide. They fish for home consumption rather than sale, and the main resource is farming. Rich crops of oats and potatoes are gathered from fields on "made ground," using seaweed, sand and manure. There are some magnificent prehistoric and early Christian hillforts and other remains. (T. W. FR.)

ARANJUEZ, a town of central Spain in the region of New Castile and the province of Madrid, lies in fertile flat land at the confluence of the Jarama and the Tagus 29 mi. S. of Madrid by road. Pop. (1960) mun. 27,251. The town was built in the mid-18th century by Ferdinand VI to a prearranged plan. Among several royal residences are the palace (completed in 1778 after being damaged several times by fire), which has a large collection of treasures, and the Casita de Labrador, built by Charles IV who abdicated at Aranjuez in 1808, which recalls the Trianons at Versailles. There are many parks and formal gardens. Aranjuez is on the main railway from Madrid to the south. Its chief industries are the manufacture of chemicals, metal products, textiles and preserved fruits. It is the centre of a rich agricultural district where asparagus and strawberries are especially important and horses are bred. (V. G. U.)

ARANY, JÁNOS (1817–1882), the greatest Hungarian epic poet, was born in Nagyszalonta, March 2, 1817, of an impecunious farming family. He went to school in Debrecen, but abandoned his studies to join for a short time a group of strolling players. Returning home, Arany found his mother dying and his father losing his sight. He reconciled himself to life at home and secured an appointment first as an assistant teacher, then as a village notary. He married an orphan Julianna Ercsey, and they lived happily with their two children. After a preliminary success, with a mediocre comic epic, in a Kisfaludy society competition, Arany made his real advent on the literary scene in 1847 with his popular epic, *Toldi* (which won him another prize from the same society). *Toldi* was received with enthusiasm by a public craving for a national literature of artistic quality in a language all could grasp. Sándar Petőfi wrote a poem in its praise, and this was the beginning of a friendship to which Arany remained loyal even after Petőfi's death. The influence of Petőfi's blazing temperament on Arany's more restrained personality was marked.

In 1848 Arany took part in the Hungarian war of independence, and for a short period edited a government newspaper for peasants. With the crushing of the revolution he lost his job and took to teaching. In 1858 he was elected a member of the Hungarian Academy and in 1860 became director of the Kisfaludy society. He moved then from Nagykörös to Pest, where he edited a literary periodical, the *Szépirodalmi Figyelő* (later the *Koszorú*), and was elected first secretary and in 1870 secretary-general of the academy. He was, however, indifferent to official recognition and reluctant to accept the honours offered him. With his "wise old peasant" mentality he found it difficult to settle down in the capital. He resigned because of ill-health in 1879 and died in Budapest, Oct. 22, 1882, an embittered man.

Arany's main epic work is the trilogy *Toldi* (1847), *Toldi szerelme* ("Toldi's Love"; 1848–79), *Toldi estéje* ("Toldi's Evening"; 1854). Its hero, a youth of great physical strength, is taken from an arid verse chronicle written by Péter Ilosvai Selymes in the 16th century. The story is set in the 14th century. In the first part of the trilogy *Toldi*, after a series of adventures recalling those of the youngest sons of folk tales, reaches the royal court. The second part tells of his tragic love and the third of his conflicts with the king, his last feat of arms and his death. Another epic poem, *Bolond Istók* ("Steven the Fool"; 1850), is a strange mixture of humour and bitterness. Though only a fragment, it is valuable for the few moments of self-revelation which Arany—usually the most reserved of authors—permits himself in it. Arany started work on a Hun trilogy, connected with Hungarian prehistory, but finished only the first part of it, *Buda halála* ("Death of Buda"; 1864). In plot and style it is reminiscent of the *Nibelungenlied*, but the characterization of the heroes is almost like that of a modern novel. The atmosphere is lowering. Archaic and folk expressions are freely used, and Arany carries language to its heights.

Arany's ballads, mostly concerned with some terrible crime and its punishment, are unparalleled in virtuosity in Hungarian literature. The poems of his two great lyrical periods are fraught with melancholy. The earlier poems, written in the 1850s, are overshadowed by the loss of Petőfi and by his despair for the Hungarian nation and for himself. The *Őszikék*, his beautiful swan songs, written just before his death, are poignant in their bitterness and sense of unfulfillment and solitude. He never published a love poem.

Arany's genius is not a loud, rebellious one. He was essentially an epic poet with a style combining exceptional lucidity and density. Even his grimmest works are relieved by his sense of humour, and his vocabulary is enriched with unusual peasant expressions. He was an infinitely painstaking worker; it would be hard to find a line in his poetical legacy which is not perfectly expressed.

Arany wrote also several essays on literature and translated Shakespeare's *King John*, *Hamlet* and *A Midsummer Night's Dream*. For his translations of Aristophanes' comedies he was awarded the Karátsonyi prize of the academy.

The best edition of Arany's collected works is by Géza Voinovich, six volumes (1951–52). (N. KI.)

ARAPAHO, an Algonkian Plains tribe, bison hunting, and tepee dwelling, on the upper Platte and Arkansas rivers at the time of the first white settlement. In the 1960s about 2,500 lived on reservations in Wyoming and Oklahoma. In addition to the northern and southern divisions now recognized, there are submerged remnants of two or three other groups—once perhaps tribally independent, since they spoke distinct dialects—and the Atsina or Gros Ventre, close to the Arapaho in speech, but chiefly associated with the Blackfoot during the 19th century. Arapaho is one of the most divergent Algonkian languages, suggesting that its speakers have been long separated from the body of the stock, presumably on or at the edge of the Plains. They were nonagricultural and clanless, kept a bundle containing a tubular pipe as tribal fetish and were divided into seven age-graded ritual societies for men and one for women, besides practising the Sun

dance in elaborate form. Their ceremonial system, decorative art and other traits indicate them as one of the nuclear or typical tribes participating in Plains culture.

They adhered vigorously to the Ghost Dance (*q.v.*), the messianic religion of 1889–91. *See* also ALGONKIAN TRIBES; PLAINS INDIANS.

Hodge (ed.), *Handbook of American Indians North of Mexico* (1959); A. Salzmann, "Arapaho VI: Noun," *Int. J. Am. Linguist.,* vol. 31 (1965).

ARARAT, a municipal city in Ripon county, Victoria, Austr., is about 1,030 ft. above sea level and 127 mi. W.N.W. of Melbourne by road. Pop. (1960) 7,934. Situated toward the western end of the western Victorian highlands, it is flanked on the south and east by a range of hills, the Pyrenees. Extensive lava flows (basalt) have occurred in this area and the soils derived from them are fertile. Ararat, with an average annual rainfall of 23–24 in., is the centre of a flourishing agricultural and pastoral area (wheat, vines, sheep, cattle). The excellent local timber resources have been exploited.

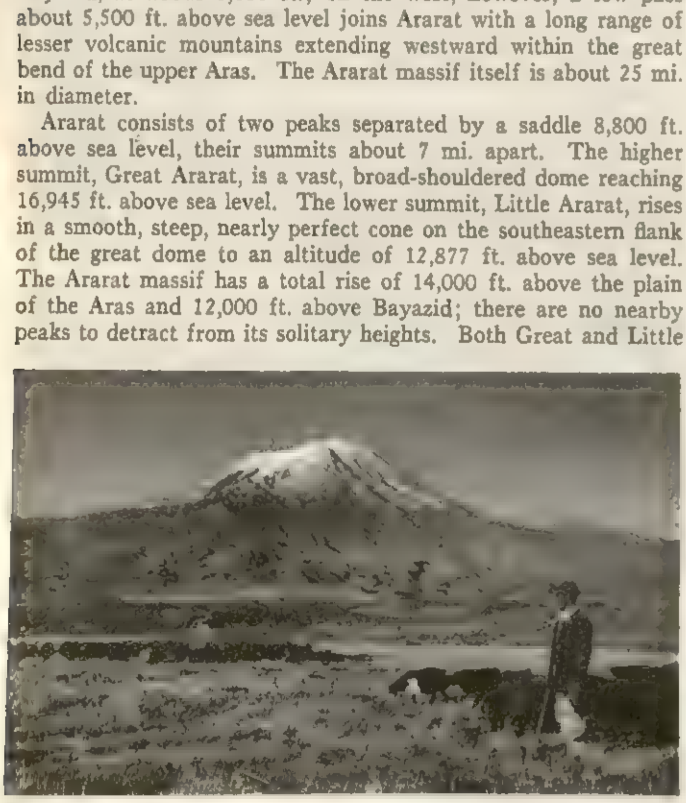
Ararat lies on the main Adelaide-Melbourne railway line and is a junction for other lines, including one to Hamilton and the rising ports of Portland and Warrnambool. Besides the railway workshops and marshalling (freight) yards important sources of employment are a fabric-weaving and hosiery-finishing mill, a psychiatric hospital and a large postal relay centre.

Ararat derives its name from Mt. Ararat (2,020 ft.), about 5 mi. S.E., so called in 1840 by the pioneer sheep-farmer H. S. Wills because, like the Ark on Mt. Ararat in Armenia, he had come to rest there. Its history began with the discovery of gold by Chinese during 1854–55, which started a big gold rush.

(J. I. GR.)

ARARAT, an extinct volcanic massif dominating the Armenian plateau, stands in Turkish territory overlooking the point where the frontiers of Turkey, Iran and Soviet Armenia converge. Its northern and eastern slopes rise from the broad alluvial plain of the Aras (Araxes) river (*q.v.*), which is there about 3,000 ft. above sea level; its southwestern slope rises from the plain of Bayazid, at about 5,000 ft.; on the west, however, a low pass about 5,500 ft. above sea level joins Ararat with a long range of lesser volcanic mountains extending westward within the great bend of the upper Aras. The Ararat massif itself is about 25 mi. in diameter.

Ararat consists of two peaks separated by a saddle 8,800 ft. above sea level, their summits about 7 mi. apart. The higher summit, Great Ararat, is a vast, broad-shouldered dome reaching 16,945 ft. above sea level. The lower summit, Little Ararat, rises in a smooth, steep, nearly perfect cone on the southeastern flank of the great dome to an altitude of 12,877 ft. above sea level. The Ararat massif has a total rise of 14,000 ft. above the plain of the Aras and 12,000 ft. above Bayazid; there are no nearby peaks to detract from its solitary heights. Both Great and Little Ararat are a result of eruptive volcanic activity, although no eruption is known to have occurred in historical times. Both consist entirely of volcanic rocks, chiefly varieties of andesite with some obsidian, and are covered with scoria and lava. Neither retains any evidence of a crater, but well-formed parasitic cones and fissures exist upon their flanks.



EITZ—PIX FROM PUBLIX

THE PEAK OF GREAT ARARAT AS SEEN FROM TURKEY

The heights of Ararat lie in the zone of perpetual snow. The snow line varies according to the season, descending in winter, the season of colder temperatures and greater precipitation, to 8,000 ft. above sea level. Both Great and Little Ararat are covered with snow as late as May. By the end of the warmer and drier summer the snow line retreats to approximately 14,000 ft. above sea level, and the snow cap occurs only on Great Ararat. The only true glacier is found on the northern side of Great Ararat, descending into the head of the great Aghuri (Akhury) chasm, a cleft in the side of the mountain extending nearly from summit to base. The middle zone of Ararat, from 5,000 to 11,500 ft., is covered with good pasture grass and some juniper, where Kurds of the area graze their sheep. Above it is sterile, black volcanic detritus, while below it is the wide sweep of thorny steppe. Most of Great Ararat is devoid of trees, but Little Ararat has a few groves of birches.

History and Legend.—The name Ararat, as it appears in the Bible ("the mountains of Ararat," Gen. viii, 4), is the Hebrew equivalent of Urardhu, or Urartu (*q.v.*), the Assyro-Babylonian name of the kingdom which flourished between the Aras (Araxes) and the upper Tigris rivers from the 9th to the 7th century B.C. The name Urartu was explained by the Babylonians as meaning "highlands," aptly referring to the mountainous character of the region. To the Armenians, Ararat refers to the province around Mount Ararat, although it was applied to the mountain itself in early Armenian literature. Today the mountain is locally known as Masis to the Armenians and Aghri Dagh to the Turks.

Mount Ararat is sacred to the Armenians, venerated by them as the Mother of the World. It is the symbol of their unity and the focal point of their traditions. Great Ararat is perhaps most celebrated as the legendary site upon which Noah's Ark came to rest as the waters of the flood subsided. The story of the Ark is still a living tradition among the Armenians, who believe themselves to be the first race of men to appear in the world after the deluge. Local legend maintains that the remains of the Ark were long visible on the mountain. Near the foot of the Aghuri chasm stood the village of Aghuri, where, according to tradition, Noah built his altar and made sacrifice after his safe deliverance from the Ark, and where he also planted his vineyard. The monastery of St. Jacob, 2,300 ft. above the village in the chasm, commemorated the monk who repeatedly tried and failed to reach the summit of the holy mountain. Both the village of Aghuri and the monastery of St. Jacob were totally destroyed by a devastating earthquake and avalanche in 1840. A Persian legend refers to Ararat as the Cradle of the Human race; the Persian name for it is Koh-i-Nuh, meaning Noah's Mountain.

In keeping with the legend of St. Jacob, the Armenians believed that God forbade anyone from reaching the top of Ararat and viewing the remains of the Ark. But on Sept. 27, 1829, Johann Jacob von Parrot (1792–1840), a German in the Russian service, made what is believed to be the first successful ascent. His accounts describe the Aghuri chasm, the village of Aghuri, and St Jacob's monastery before the great landslide. Professor Hermann Abich, a German geologist, climbed Ararat in 1845 and described the immediate effects of the Aghuri avalanche. Since then the mountain has been climbed many times by Europeans. From a mountaineering point of view the ascent is said not to be difficult, requiring only considerable endurance. (D. D. CR.)

ARAS (Russian ARAKS, Persian RUD-E ARAS, Turkish ARAS NEHRI, anc. ARAXES), a river which rises south of Erzurum (*q.v.*)

in the Bingol Daglari of Turkish Armenia. It flows eastward, forming between longitude 41° 20′ E. and 48° E., or approximately 280 mi., the international boundary between the U.S.S.R. on the north and Turkey and Iran on the south. Approximately 568 mi. long, it joins the Kura river in Azerbaijhan S.S.R. about 75 mi. from its mouth on the Caspian sea. Since a flood in 1897 a separate distributary of the Aras also empties into the Caspian. The swift-flowing Aras accounts for most of the sediment comprising the Kura-Aras delta. The principal tributaries of the Aras are the Zanga, draining Lake Sevan (Gokcha), and the Qara Su, which flows off the Kuh-i-Savalan in northeastern Iranian Azerbaijan. On an island in the river, in the shadow of Ararat (*q.v.*), stood Artaxata, the capital of Armenia from 180 B.C. to A.D. 50. (D. D. Cr.)

ARASON, JÓN (*c.* 1484–1550), last Roman Catholic bishop in Iceland, is remembered as a national, no less than as a religious, hero. The son of poor parents, he rose quickly to eminence in the church and was consecrated bishop of Hólar, the northern diocese of Iceland, in 1524. He administered his diocese prosperously until Christian III of Denmark began to impose Lutheranism on all his subjects. The two Icelandic bishops, Jón in the north and Ögmundr in the south, protested (1537). Ögmundr was deported by the Danes in 1541, but Jón continued his resistance. He captured the Lutheran bishop Marteinn and seized his see (1549–50), but was soon afterward taken by the king's agents and beheaded with two of his sons in Nov. 1550.

Jón was the author of splendid religious and satirical poetry and brought the first printing press to Iceland.

See Knut Gjerset, *History of Iceland* (1922). (G. T.-P.)

ARATUS (*c.* 315–*c.* 245 B.C.), Greek poet of Soli in Cilicia, is best remembered for his poem on astronomy, *Phaenomena.* He resided at the courts of Antigonus Gonatas, king of Macedonia, and Antiochus I of Syria, and died in Macedonia about 245 B.C. The *Phaenomena,* a didactic poem in hexameters is his only completely extant work. Lines 1–757 versify a prose work on astronomy by Eudoxus of Cnidos (*c.* 390–337) while lines 758–1154 treat of weather signs and show much likeness to Pseudo-Theophrastus' *De Signis Tempestatum.* The poem became immediately popular and provoked many commentaries, the most important of these being that by Hipparchus (*c.* 150 B.C.), still extant. In form the *Phaenomena* belongs to the Alexandrian school, but the author's Stoicism adds a strong note of seriousness. It enjoyed a high reputation among the Romans. Cicero, Caesar Germanicus and Avienus translated it; the two last versions and fragments of Cicero's survive. One verse from the opening invocation to Zeus has become famous from being quoted by St. Paul (Acts xvii, 28).

ARATUS OF SICYON (271–213 B.C.), Greek statesman, who for many years was the leading spirit of the Achaean league (*q.v.*). From Argos, his home after his father's murder (264 B.C.), he liberated Sicyon (251), established a democracy there and united it with the Achaean league for defense against Macedonia. He solved its economic difficulties with subsidies from Ptolemy II of Egypt. As general of the league (a post he normally held each alternate year after 245), he captured Acrocorinth (243), defeated the Aetolians at Pellene (241) and pursued a policy of establishing democracies in the Peloponnese. With Aetolia as ally from 239, he repeatedly attacked Athens and Argos. He brought Megalopolis (235) and Argos (229) into the league and helped to liberate Athens from Macedonian rule (229). Spartan aggression threatened these gains. Twice defeated by Cleomenes III, Aratus sought help from Macedonia, and the league was saved by Antigonus Doson's arrival (224). In 222 Cleomenes was defeated and dethroned. On the accession of Philip V of Macedonia, Aratus countered Aetolian aggression by appealing to Antigonus Doson's new Greek league; in the subsequent war (the "Social War") he successfully defeated the anti-Achaean policy of the court cabal led by Apelles. After the peace of Naupactus (217) he resisted Philip's anti-Roman policy and his interference in Messene. His death (213), probably from consumption, was popularly laid at Philip's door. Aratus' memoirs no longer survive; they formed an important source for Polybius' *History.* Aratus sometimes indulged personal rancour against his rivals, but his general policy was statesmanlike. He failed to build up a strong army; but his main decisions were almost invariably right, and as a diplomatist and guerrilla fighter he achieved greatness through adapting himself to circumstances.

ARAUCA, a western tributary of the Orinoco river (*q.v.*). It rises in the eastern cordillera of the Andes near the Venezuelan-Colombian border and empties into the Orinoco about 60 mi. southeast of San Fernando de Apure. Its course is about 430 mi. long and forms part of the Venezuela-Colombia boundary for approximately 135 mi. in the upper course.

The Arauca takes a relatively straight, almost direct east-west course across the llanos (plains) and flows nearly parallel to the Apure and the Meta. The level nature of the vast plains, combined with the seasonal rainfall, result in such widespread flooding during the rainy season (April to November) that the waters of the Arauca and the Apure sometimes mingle. Since the flow of the rivers down the gentle slope of the llanos is relatively straight, the Arauca has few tributaries.

The river is navigable by small craft but is little used. (D. R. D.)

ARAUCANÍA, an area of southern Chile between the Bío-Bío and Toltén rivers within which Araucanian (*q.v.*), or Mapuche, Indians maintained independence of Spanish and Chilean authority until late in the 19th century, despite periodic methodical campaigns of reduction. During one of the final operations Temuco (*q.v.*) was founded (Feb. 23, 1881) on a strategic site ceded in the treaty signed on Cerro Ñielol. Settlement of the conquered area by Chileans and Europeans was encouraged by the government. Land was reserved for the Indians, a people whose process of incorporation into national life continues. Arauco, Bío-Bío, Malleco and Cautín (*q.v.*) provinces occupy Araucanía. (J. T.)

ARAUCANIAN is a language group of the Andean Equatorial phylum and the generic name given to Indians speaking any of its several mutually-intelligible dialects and living in southern middle Chile and Argentina. Most is known about Chilean Araucanians who are traditionally described as belonging to three major geographical and cultural divisions, *Picunche* (*picun* "north," *che* "people"), *Mapuche* (*mapu* "land"), and *Huilliche* (*huilli* "south"). The Picunche were defeated and assimilated by the Spaniards before the end of the 17th century and the Huilliche, for the most part, are now culturally indistinguishable from rural mestizos among whom they live. It is the approximately 200,000 Mapuche, who inhabit the central valley and the Andean foothills from the Bío-Bío river to an ill-defined zone south of the Toltén river, who represent contemporary Araucanian society in Chile. The Argentine Araucanians are descendants of *émigrés* from Chile who crossed the Andes in great numbers at certain periods during more than 400 years of troubled relationships with white colonists and soldiers. Today, social contacts are still sustained between these two Araucanian populations who share a common culture and a similar social organization.

The Mapuche defended their territory against white invaders until their final defeat in the War of 1880–82, after which they were forced to settle on several thousand small, family-based reservations in southern middle Chile, where they are found today. During the centuries of hostilities the Mapuche were desultory horticulturalists and herders of horses, sheep and cattle. They shifted their small settlements frequently, according to the exigencies of warfare. With the establishment of the present reservation system the Mapuche population has become sedentary, and agriculture has taken on greater importance as new crops (wheat, barley, oats) have been added to the traditional inventory (maize,

potatoes, quinoa, beans) and as ox-traction plowing has spread throughout their territory. The Mapuche have become increasingly dependent on Chilean regional markets for sales, purchases and the establishment of credit. Young men and women continually leave the reservations to find work or attend schools in Chilean and Argentine towns. Many cultural changes have taken place. (*See* also CHILE: *The People and Population.*) Nevertheless, Chilean as well as Argentine Araucanians comprise one of the largest functioning indigenous societies in South America. They are culturally and socially distinctive from peoples who surround them. They maintain characteristic kin and marriage relationships, based on patrilineal organization. Their traditional religion, influenced by Christianity, is still practiced and involves beliefs in ancestral spirits and a hierarchy of mythological deities.

ARAUCARIA, a genus of coniferous trees included in the tribe *Araucarineae.* They are magnificent evergreen trees, with apparently whorled branches, and stiff, flattened, pointed leaves, found in Brazil and Chile, the Phoenix Islands and Australia. The name of the genus is derived from Arauco, the name of the district in southern Chile where the trees were first discovered. *Araucaria araucana,* the Chile pine, or "monkey puzzle" as it was called because it was hard to climb, was introduced into Britain in 1796. It is largely cultivated, and usually stands the winter of Britain; but in some years, when the temperature has fallen very low, the trees have suffered much. Care should be taken in planting to select a spot somewhat elevated and well drained. The tree grows to the height of 150 ft. in the Cordilleras of Chile. The cones are from eight to eight and one-half inches broad, and seven to seven and one-half inches long. The wood of the tree is hard and durable.

This, as well as other members of the genus, is cultivated on the Pacific coast of the U.S., particularly in California, and also in some cases in southern Florida. They are valued for the conspicuous growth habits which set them apart from nearly all other conifers commonly grown. *Araucaria excelsa,* the Norfolk Island pine, a native of Norfolk Island and New Caledonia, was discovered during Captain James Cook's second voyage and introduced into Britain by Sir Joseph Banks in 1793. It is tender but finds some use as a house plant during its sapling stage, because of the beauty of its symmetrically tiered growth. It is not often found out of doors in the United States, where *A. cunninghamii,* the Moreton Bay pine, *A. bidwillii,* the bunya-bunya pine and *A. angustifolia* are more frequently met.

E. AUBERT DE LA RÜE

PARANA PINE (ARAUCARIA ANGUSTIFOLIA) OF BRAZIL

ARAUCARIACEAE. This family of conifers (*q.v.*) has only two genera and about 32 species; it includes some of the largest gymnosperms, and is restricted to the southern hemisphere. They are extremely important as timber trees, are used in the manufacture of paper pulp, and are the source of important resins (obtained often in fossilized condition) such as kauri gum and copal. The genus *Agathis* includes about 20 species of the Australasian area, while *Araucaria,* with about 12 species, ranges from this area to South America. Four species of *Araucaria* are cultivated commonly in temperate regions: *A. excelsa* (Norfolk Island pine) *A. cunninghamii* (Moreton Bay pine), *A. araucana* (monkey puzzle tree), *A. bidwillii* (bunya-bunya).

The Araucariaceae are large, monoecious or dioecious trees with needlelike or broad leaves. The large, cylindrical staminate, or pollen-bearing, cones are borne on the ends of short axillary branches. The numerous scales bear 5 to 20 pendent sporangia. The ovulate, or seed-bearing, cones are often extremely large and heavy and are borne on the ends of short branches. The numerous cone scales are composed of a bract and an ovule-bearing scale fused their entire length. Each cone scale bears a single, inverted ovule. Only simple polyembryony occurs in the Araucariaceae. The single surviving embryo has two to four cotyledons. (R. W. H.)

ARAUCO, a small coastal range province of southern Chile, approximately bisected by latitude 37° 30′ S. Area 2,023 sq.mi.; pop. (1960) 89,504. Created in 1852, the province sustained various areal changes before being merged with Concepción province in 1928. It regained provincial status in 1934. There are three departments: Arauco, which includes Santa María Island; Lebu; and Cañete, which includes Mocha Island. The provinces adjoining are Concepción (north), Bío-Bío and Malleco (east) and Cautín (south). Arauco's hilly terrain culminates in the forested Cordillera de Nahuelbuta, the divide marking both the eastern boundary of the province and the headwaters of most of Arauco's streams. The area receives abundant rainfall; the maximum occurs in winter but no month is rainless. Winters are cold and summers cool.

At the time of the Spanish conquest this area was skilfully defended by the Araucanian Indians (*q.v.*). The fierce fighting between Spaniards and Indians near Cañete in the 16th century cost the lives of two of Chile's most famous warriors, Pedro de Valdivia (*q.v.*) and the Araucanian chieftain Caupolicán (*q.v.*). Indians overwhelmed the fort at Arauco three times before 1662; they remained strong enough to attack again in 1723, 1766 and 1817. It was not until well after Chile had gained its independence that the Chilean army pacified (1861–67) most of this part of Araucanía (*q.v.*). Thereafter agriculture and coal mining were developed, although with limited economic benefits to the province. Arauco's soil and mineral wealth are of modest importance. A fair acreage of wheat, potatoes, oats and peas is grown; cattle and sheep are common in the open brush and forest range; and the forests produce lumber and tanning materials. Husbandry supports about half of the gainfully employed, coal mining about 10%. The province produces about 15% of Chile's coal. The mines of Colico, Curanilahue and Arauco are served by rail from Concepción (*q.v.*). Lebu, a lesser mining centre, minor port and provincial capital since 1875 (pop., [1960] 6,248), has rail communication with Cañete (5,487) and the longitudinal railway. All-year roads are maintained from the capital to Curanilahue, Cañete and Quidico. Lebu, Arauco and Lake Lanalhue, southeast of Cañete, attract summer vacationers. (J. T.)

ARAUSIO, BATTLE OF, the defeat of a Roman army by Germanic tribes on Oct. 6, 105 B.C., near Arausio (the modern Orange in southern France). The Cimbri and the Teutones, Germanic peoples from north of the Alps, had invaded the Roman province of Gallia Narbonensis (*see* GAUL) *c.* 110 B.C. The consul Gnaeus Mallius Maximus, sent from Italy in 105 with an army to reinforce that of Q. Servilius Caepio (Roman proconsul in Gaul from 106), began negotiations with the invaders, but during the negotiations Caepio attacked the Cimbri. Caepio was over-

whelmed, and the consul's army, drawn into the fighting, also was destroyed. Instead of advancing into Italy, however, the Cimbri went into Spain and the Teutones wandered in Gaul. The disaster and the urgent need to raise new forces accelerated the process whereby the Romans replaced their traditional citizen soldiery with a long-service professional army.

ARAVALLI RANGE, an Indian hill system running for 300 mi. in a northeasterly direction through Rajasthan state, is situated between 24° and 27° N., and between 72° and 75° E. The series of ridges and peaks, with breadth varying from 6 to 60 mi., are generally from 1,000 to 3,000 ft. in elevation, the highest point, Mount Abu (5,650 ft.), being in the extreme southwest. Geologically the Aravalli range is built up of Pre-Cambrian metamorphic rocks, especially gneisses, schists and slates. Masses of rose-coloured quartzite give a dazzling snowlike appearance to some of the peaks.

The Luni and Sakhi rivers from the steep northwestern slopes turn southwest to the Gulf of Kutch. Two distinct river systems drain the southeastern slopes; one debouches in small streams on the Gulf of Cambay, while the other unites to form the Chambal river, a tributary of the Jumna and the Ganges system. The Aravalli hills are for the most part bare and thinly populated, with large areas of sand and stone, or huge masses of quartz. The valleys are generally sandy deserts, with sparse oases of cultivation. Occasionally, however, a fertile tract marks a natural drainage line, *e.g.*, that of Ajmer (*q.v.*) city, with its lake. The Aravalli hills send off rocky ridges northeast through the state of Rajasthan, which reappear in the form of isolated hills near Delhi.

(L. D. S.)

ARAWAK, a name applied by the Spanish to various groups of Indians in the West Indies and in South America who spoke related languages. The term is now used to refer to a major family of South American Indian languages which were spoken not only in the Caribbean and in northern South America but as far south as the Gran Chaco.

The Arawakan-speaking Indians whom Columbus met in Hispaniola and the other islands of the Greater Antilles were a peaceful agricultural people who granted their chiefs great deference and were organized into fairly large political units. In spite of their superior organization, however, they seem to have been unable to withstand the attacks of the Carib, who had driven the Arawak out of the Lesser Antilles shortly before the arrival of the Spanish (*see* CARIB).

In South America, Arawakan-speaking tribes occupied large areas in the northern and western parts of the Amazon basin, where they shared many traits with the other peoples of the tropical forest. Sedentary farmers who did considerable hunting and fishing, they lived in small settlements in large thatched houses, made baskets and pottery, wove hammocks, and traveled in dugout canoes. Their chiefs had little authority and each village was independent of all others. Religion centred around curing individuals, although some ceremonies were held for the benefit of the whole community. A few of the Arawakan tribes in the Guianas were cannibals, but this practice was more characteristic of their neighbours and traditional enemies, the Carib.

The most western Arawak, the Campa and neighbouring tribes, lived in the foothills of the Andes but do not seem to have been much influenced by the Andean civilizations. To the south, in eastern Bolivia, the Mojo had a political organization similar to that of the Antillean Arawak, with several communities being under the control of a paramount chief.

ARBELA: *see* IRBIL; GAUGAMELA, BATTLE OF.

ARBENZ GUZMÁN, JACOBO (1913–), president of Guatemala, under whom the Communists reached positions of national influence, was born in Quezaltenango on Sept. 14, 1913, and graduated from the military academy at Guatemala City in 1935 at the top of his class. María Cristina Vilanova Castro, whom he married in 1939, is generally credited with leading Arbenz toward the acceptance of Marxism. After playing a major role in the revolution of Oct. 20, 1944, which opened the way for the establishment of a democratic government in Guatemala, he became a member of the triumvirate that governed until the inauguration of Juan José Arévalo as president in March 1945. As Arévalo's minister of defense, Arbenz became the presidential candidate of the leftist forces. His road cleared by the assassination of his chief rival, Francisco Arana, he was elected president in Nov. 1950 and assumed office the following March. Organized labour soon came completely under the control of the Communists, several of whom occupied important positions in the government. Following the enactment of a program of agrarian reform in July 1952, Guatemala moved rapidly toward open class warfare and became the centre of international controversy. The situation continued to deteriorate until finally on June 18, 1954, civil war broke out. After a week of indecisive fighting, the army withdrew its support; Arbenz resigned on June 27 and shortly thereafter went into exile. Following an extended visit to eastern Europe, the Soviet Union and Communist China, Arbenz moved to Uruguay in 1957 and later to Cuba. *See* GUATEMALA: *History*.

(R. M. Sc.)

ARBER, EDWARD (1836–1912), English man of letters, whose editing of Elizabethan and Restoration literary texts first made detailed study of them possible to the ordinary student, was born in London, Dec. 4, 1836. He became a clerk in the admiralty office in 1854 but used his leisure to study literature and in 1878 was appointed lecturer in English at University college, London. He was professor of English at Birmingham, 1881–94, and a fellow of King's college, London, from 1880. He was knocked down and killed by a taxicab in London, Nov. 23, 1912.

Arber's publication at a reasonable price of rare texts opened up new opportunities for scholars and students. His editions of many texts remain the only ones easily accessible. His *English Reprints*, 30 vol. (1868–71), began with a 6*d*. edition of Milton's *Areopagitica*. Later series were *An English Garner*, 8 vol. (1877–96); *The English Scholar's Library*, 16 vol. (1878–84); and *British Anthologies*, 10 vol. (1899–1901). Equally valuable were his bibliographical *A Transcript of the Registers of the Company of Stationers of London, 1554–1640*, 5 vol. (1875–94), and *The Term Catalogues, 1668–1709*, 3 vol. (1903–06), edited from the booksellers' quarterly lists.

ARBITRAGE, a business operation in which funds, gold, commodities or securities are sent from one place to another to take advantage of temporary price differences that exceed transfer costs. Undertaken only for virtually certain profit with practically no risk, it is not a form of speculation. The operation, however, is impossible without some freedom of movement of the means of arbitrage. When they move unrestrictedly, the price disparity can be only temporary—unless the knowledge of market conditions remains imperfect or the supply of the means of arbitrage continues to be limited. Opportunities for arbitrage may keep recurring because of the working of the supply-and-demand forces in the market.

In less developed countries a common arbitrage activity consists in the buying and selling activities of the peasant or traveling merchant plying between nearby village markets. He is able to profit when a price disparity persists due to the difficulty of communication, the lack of sufficient supply, and the nonstandardization of weights and measures. Equally common in these countries is the shifting of funds from one city to another in the same country to take advantage of substantial differentials in interest rates. In highly developed countries, however, opportunities for arbitrage at home are far less extensive, and the term is generally used to refer to international operations in respect of foreign exchange rates, short-term interest rates, prices of gold and prices of securities.

Foreign-exchange arbitrage proper is confined to spot exchange markets where exchanges are bought and sold for immediate de-

livery. For purposes of illustration, the differential between buying and selling rates, fees and commissions, the possible loss of one day's interest and the cost of cables and telephones are ignored. Assume that at a given time the New York rate for sterling is \$2.80 while the London rate is \$2.81. Under the circumstances a New York operator will instruct his banking correspondent in London by telephone to use a specified amount of his sterling balance to buy dollars immediately for cable transfer to New York, and simultaneously buy sterling in New York to replenish his London account. By so doing, he will make one cent on every \$2.80. This opportunity for sure profit, known to many operators in New York, London and other money centres, will disappear in a matter of minutes. The increase in demand for dollars in London and the increase in demand for sterling in New York will harden the sterling value sufficiently to make the rates in both markets identical at a new level of, say, \$2.80½.

The example above is known as a two-point arbitrage, involving simultaneous purchase and sale in two exchange centres. The same principle applies to three-point or multiple-point arbitrages when three or more centres are involved. Given the rates of \$2.80 to a British pound and \$2.04 to 1,000 French francs in New York, operational parity means not only identical rates for the American dollar in London or Paris, but a cross-rate of £1 to 1,372.55 francs ($= 2.8 \times 1000 \div 2.04$) between them. Now suppose the franc rate in New York and Paris suddenly drops to \$2.00, with the sterling rate in New York and the cross-rate between Paris and London unchanged at the moment. A New York operator, with \$100,000 at his disposal, may then make three moves: (1) buy 50,000,000 francs in New York in the form of a cable transfer to his Paris account; (2) instruct his correspondent in Paris by telephone to use a similar amount of francs to buy at the current rate £36,428.11*s*.5*d*. in the form of a cable transfer to his London account; and (3) sell the same amount of sterling in New York at \$2.80 for a total of \$102,000. Thus, within a few minutes the original amount of working funds is returned with a profit of \$2,000. The heavy demand for francs in New York may push the rate back to \$2.04, restoring the old operational parity. Should the franc continue to weaken in the New York market, arbitrage will go on until the franc depreciates equally in all exchange centres and the new cross-rate between London and Paris becomes £1 to 1,400 francs ($= 2.80 \div 2.00$).

Pure arbitrage in foreign exchange has been curtailed by the establishment of equalization funds in various countries. The administrators of such funds may "peg" the exchanges so effectively that arbitrage profits are eliminated.

The opportunity for a different type of arbitrage, interest arbitrage, arises when, say, the three-month money rate in London is 3% per annum compared with 2% in New York. To take advantage of this differential, a New York operator will either purchase three-month sterling bankers' acceptances in the market at a discount of close to 3% and hold them until maturity, or transfer funds to London to invest in prime papers. (The price of sterling acceptances and the spot sterling rate will rise.) Simultaneously, hedging against unfavourable exchange fluctuations at the end of three months when the proceeds will be brought back, he sells sterling in New York for three-month delivery. Heavy sales of forward sterling will carry the forward rates to a growing discount against the spot rate, which may soon wipe out the profit margin. Meanwhile the flow of funds will stiffen the money rate in New York and soften that in London. The new equilibrium will be found in a combination of a narrowing interest differential between the two centres and a falling price of forward sterling which eliminates any incentive to arbitrage.

Gold arbitrage and securities arbitrage operate, in principle, very much like commodity arbitrage in the domestic market, except that in the two former cases exchange rates are important either because funds have to be remitted abroad for the operation or because the proceeds have to be brought home at the end of the operation. (CH.-M. L.)

ARBITRATION, in law, an arrangement for settling a dispute by calling upon the judgment of a selected person or persons rather than taking the matter into the established courts of justice. This article is restricted to the use of arbitration in commercial matters; the arbitration of labour disputes is discussed in INDUSTRIAL RELATIONS, while methods of settling disputes between nations are described in ARBITRATION, INTERNATIONAL.

United States.—Arbitration generally followed the pattern of the English common law until 1920, when New York adopted the first modern arbitration statute. Previously, agreements to arbitrate disputes that might arise in the future could be revoked at any time prior to an actual settlement. Such agreements were held nonenforceable, although not illegal, on the theory that they would deprive the courts of jurisdiction. Following adoption of the New York statute, the federal government (in 1925) and 15 states enacted similar statutes. The federal act does not prescribe a rule of decision for all cases in the federal courts but is confined to subjects within federal legislative control, namely, maritime transactions and those involving interstate commerce. In other cases that may be litigated in the federal courts, *e.g.*, in suits between citizens of different states, the law of the state in which the federal court sits either provides the controlling law on arbitration or points to the law of the appropriate state.

In the early 1960s all states with the exception of Oklahoma and South Dakota had some statutory provisions for arbitration. Not all, however, provided for enforcing an agreement to arbitrate future disputes; many followed the rule that none but existing controversies could be made the subject of an agreement to arbitrate. A Uniform Arbitration act that would validate agreements regarding both existing and future disputes was adopted in 1955 by the Commissioners on Uniform State Laws and approved by the American Bar association. This act, if adopted generally, would bring into conformity those state laws not providing for future disputes. It also would simplify arbitration proceedings and the enforcement of awards.

Although individuals frequently agree, either by contract or after a dispute has arisen, that a dispute will be arbitrated by some specific procedure, the majority of arbitrations are held under the auspices of organizations that have procedures for arbitration as an explicit part of their trading rules, bylaws or constitutions. Such institutional arbitration has a long history. The New York Chamber of Commerce had arbitration facilities from at least 1761 to 1920, and the New York Stock exchange provided for arbitration of members' disputes in its 1817 constitution. Trade associations frequently provide the machinery for settling disputes among members, and occasionally such facilities are available to nonmembers as well. In some instances an association has joined several others to provide joint arbitration machinery. Additional facilities for handling disputes by arbitration were made available through the auspices of the American Arbitration association, a nonprofit-making organization that maintained panels of arbitrators and provided administrative services for judging both labour and commercial disputes. (S. M.; X.)

England.—The Arbitration act of 1950 (which consolidated the Arbitration acts, 1889 to 1934) provided a code regulating all arbitrations made as a result of written agreements between the disputing parties, as well as certain arbitrations conducted under statutory provisions; however, if the parties to a dispute so agree, many provisions of the 1950 act need not be observed.

Apart from the Arbitration act itself, there are many statutes providing for the arbitration of special classes of disputes. Arbitration is made compulsory in statutes dealing with agricultural holdings, housing and the acquisition of land. Disputes in connection with building societies, companies, compulsory purchase of land, public health and rent restriction may be arbitrated at the option of the parties involved.

An arbitration agreement is defined as a written agreement to submit existing or future disputes to arbitration; it may or may not specifically name an arbitrator. Unless the agreement provides otherwise, the authority of the arbitrator is irrevocable except by order of the court or a judge. For example, if an arbitrator has misconducted himself by showing partiality, the court has the power to remove him or to set aside his decision.

The court has two ways in which it may compel parties to carry out an arbitration: directly, by appointing an arbitrator or by

allowing one appointed by one of the parties to proceed alone with the arbitration; and indirectly, by staying any proceedings before the legal tribunals to determine matters within the scope of arbitration. However, the court will refuse to stay proceedings where the subject matter of the litigation falls outside the scope of the arbitration, where there is some serious objection to the fitness of the arbitrator, or where some other good reason of the kind exists, such as there being an important question of law involved.

When two arbitrators and an umpire are to be appointed, the umpire must be named by the arbitrators (in order to make an award should the arbitrators fail to agree) immediately after they are appointed; in cases of disagreement, the court may appoint an umpire.

An arbitrator or umpire has the power to administer oaths to, and take the affirmations of, the parties to the dispute and their witnesses, and the customary penalties for perjury apply to such proceedings.

An award in an arbitration case may be made at any time, if no specific time limit has been provided for in the arbitration agreement. However, if the arbitrator or umpire delays unduly in making an award, the court has the power to remove him. Where the time for making an award has been fixed in the agreement, that time may be extended by the court or judge. In cases where the court may remit an award to the arbitrators or umpire for reconsideration, the reconsidered award must be made within three months.

An award must dispose of all the points referred to the arbitrators and it must be final, except as regards certain matters of valuation. However, an award may be set aside in cases where the arbitrator has misconducted himself, where he has been willfully deceived by one of the parties or where there is a prima-facie error of law. An award may be enforced, by leave of the court, in the same manner as a judgment or decree to the same effect. An arbitrator may, and shall if required by the court, state in the form of a special case for the opinion of the court any question of law arising in the arbitration.

(A. W. R.; H. Sle.; X.)

Other Countries.—Commercial arbitration procedures are much the same in all countries, differing locally in matters of detail. In countries that have felt British influence, legislation generally follows the pattern of English law. However, in Scotland, the law on arbitration is almost wholly common law. There is no statutory code, although contracts for arbitration always have been enforced by the courts.

In France, a distinction is made between the formal submission of an existing dispute and an agreement to submit future disputes that arise out of a definite legal relationship between the parties, the latter being most common. The French code excludes arbitration that is not based on a formal submission; hence, an arbitration clause is construed as a promise to sign a submission when a dispute arises.

ARBITRATION, INTERNATIONAL. Arbitration is a process for the settlement of disputes based on the consent of the parties in conflict. By their agreement, the controversy is referred to a third party for a final decision or award. It is to be contrasted with conciliation or mediation (*q.v.*), in which the role of the third party is to persuade the parties to the dispute to accept a settlement, rather than to impose upon them a binding decision.

International arbitration contemplates the final settlement of disputes between states or bodies having legal personality in international law. It implies the reference of such a dispute by the consent of the parties to a tribunal of their own selection for a decision which will be binding upon them. As defined in the Hague convention of 1907, international arbitration has for its object the settlement of disputes between states by judges of their own choice on the basis of respect for law.

Arbitration between states differs from arbitration between private persons in a number of respects. The differences basically stem from a difference in attitudes toward the two processes. International arbitration although distinguished from international judicial settlement (*see* League of Nations covenant, art. 13; United Nations charter, art. 33) is a process of adjudication. The international arbitral tribunal proceeds "on the basis of respect for law." International law governs its creation, its functioning and the binding force of its judgments. On the other hand, private arbitration is regarded as a mechanism or device for the settlement of controversy. Private arbitrators are not perceived as judges.

As a consequence, an arbitration treaty may not lawfully be revoked by the act of one of the parties whereas a private agreement to arbitrate may be. An international tribunal may determine its own jurisdiction, subject to no superior body. A decision on jurisdiction by private arbitrators is subject to review by the courts. A domestic arbitration award need not be supported by reasons; an international award must be. An international award is itself binding and, unlike a domestic award, needs no court order to render it enforceable.

International arbitration may look to the settlement of existing disputes (*ad hoc* arbitration) or of future disputes. States have rarely entered into agreements to settle all their future disputes by arbitration or judicial means. Usually such agreements are subject to limitations, such as the requirement that resort to arbitration cannot be had unless diplomatic negotiation or conciliation shall have failed to settle the dispute. Other agreements limit arbitration of future disputes to those which involve rights, are of a legal nature or are capable of decision by the application of legal principles. Still other agreements specifically exclude disputes of a political nature or those which involve matters of domestic jurisdiction, sovereign rights or vital interests.

International law assures states that when they decide to arbitrate their differences, the terms of their agreement will be respected by each of them and by the arbitral tribunal, that the tribunal will observe the minimum procedural standards observed by courts of law generally, that the award of the tribunal will be confined to the matters submitted to it and that the tribunal will apply the law laid down for it.

The extension of the arbitral process to the settlement of political, as well as legal, disputes is in part a problem in reconciling conflicting values or viewpoints of nations and in part a problem in the growth of international law. When national feelings run high, the parties may accept mediation but refuse arbitration, since mediation is not binding whereas arbitration is. Yet even if the necessary readiness to accept arbitration should exist, there is still the problem of the basis upon which the tribunal shall decide the dispute. If the dispute is of a legal character, it is susceptible to decision by international law. If, however, it is of a political character, international law may not provide applicable rules for decision. International law represents a limited body of rules growing out of the practice of states and based on their consent. In many areas, such as economic relations, no rules were developed to limit the exercise of state power. These are termed the sphere of sovereignty or of domestic jurisdiction. If a dispute arising in such an area were to be decided on the basis of international law, the result would always be in favour of complete state freedom. Yet this very freedom from restraint by law is the ultimate source of the dispute.

To some extent, the lag in the growth of international law, as compared with the growth of international society, is met by treaty regulation. Treaties not only provide new rules or create new agencies to deal with new international problems but often include provisions for the arbitration or judicial settlement of disputes arising under them. Illustrative of this development are the Convention on International Civil Aviation, the constitution of the Food and Agriculture organization and the agreement of the In-

ternational Bank for Reconstruction and Development.

When, however, states desirous of settling their disputes peacefully are faced with the lack or inadequacy of customary rules of international law, they must give the tribunal greater freedom than merely the resort to international law as a basis for decision. One approach in such circumstances is to provide for a decision *ex aequo et bono* or on the basis of equity. In international practice, this means a decision consistent with the general principles of justice, faithful to the spirit of the law and supplementing and filling in its gaps in an objective manner. Another approach is to provide for a decision in accordance with the "general principles of law recognized by civilized nations," a term first used in international jurisprudence in the statute of the Permanent Court of International Justice and continued in the statute of the International Court of Justice.

In support of the latter approach, it has been asserted that the principles evolved by the legal systems of civilized states are of a maturity and breadth which would make it possible for all conflicts between states to be decided on a basis of law, even in areas where customary international law has not developed rules. On the other hand, others have contended that it is fallacious to assume that international arbitration can be relied upon to settle basic conflicts of power in the international sphere. They say that in such conflicts the issue is not who is right and who is wrong but what ought to be done to combine the particular interests of individual nations with the general interest in peace and order. Such a question, they say, cannot be answered by a lawyer but only by a statesman.

Arbitration has been used for settling international claims, such as claims of a state on behalf of its nationals based on denial of justice by another state. Cases in this field, known as the responsibility of states, have probably occupied the largest volume of litigation before international tribunals; there are literally thousands of such decisions. A number of diplomatic episodes of importance have been decided by arbitration, notably by the Permanent Court of Arbitration established under the Hague conventions of 1899 and 1907. Boundary disputes, many with a stormy diplomatic history, have been frequently resolved by arbitration.

History of Arbitration.—The history of arbitration goes back to antiquity. It was practised occasionally between the various city-states of ancient Greece. It was resorted to between the 12th and the 15th centuries in the relations of the various political units of western Europe, the Italian cities and the cantons of Switzerland. Modern international arbitration, conceived as a procedure based on the application of rules of law, may be said to have begun with the Jay treaty of Nov. 19, 1794, between Great Britain and the U.S. In that treaty the parties submitted to adjudication by mixed commissions matters of considerable importance, such as determination of boundary disputes relating to vast stretches of territory, as well as acute controversies bearing upon the exercise of belligerent rights at sea by Great Britain during its war with France and the fulfillment by the U.S., in the same war, of its obligations of neutrality.

While in the 19th century a number of arbitrations between other states took place, much of arbitral practice in that century was due to agreements between the U.S. and Great Britain. These covered not only mixed commissions, sitting over long periods, for the determination of boundary disputes and pecuniary claims such as those established by the treaty of Ghent of 1814, by the treaty of 1853 and by the treaty of Washington of 1871; they also revealed the political and legal potentialities of international arbitration by submitting successfully to legal determination complex and delicate political issues. Thus, in 1870 the two states ended a prolonged and embittered controversy by agreeing on arbitration with regard to the claims of the U.S., based on alleged violations of neutral obligations by Great Britain in the American Civil War, in the matter of the "Alabama" and other vessels. The U.S. claim for arbitration was originally rejected by Great Britain on the ground that it would have been contrary to the honour of the government to submit to arbitration the question whether it had acted in good faith in the fulfillment of its neutral duties (*see* "ALABAMA" ARBITRATION).

The British Guiana arbitration of 1897 was between Great Britain and Venezuela, but it was an arbitration in which U.S. counsel and U.S. arbitrators played prominent parts. It was brought about largely as the result of extreme political pressure on the part of the United States, which invoked the Monroe Doctrine on the ground that any European state refusing to submit to arbitration a territorial dispute with an American state in fact attempts to annex American territory in disregard of the Monroe Doctrine.

The Bering sea arbitration of 1893 involved, in an acute form the question of the freedom of the sea. The awards in all these arbitrations were preceded by an elaborate written and oral argument—the latter lasting in some cases for weeks. They more than any other factor, were responsible for raising the prestige and revealing the possibilities of international arbitration.

The Permanent Court of Arbitration.—The success of international arbitration during the 19th century and considerations of international peace prompted the adoption, at the first Hague conference, of the convention (Convention no. I) on the pacific settlement of international disputes. That convention apart from short chapters on mediation and commissions of inquiry, was concerned exclusively with international arbitration In approaching that question, the conference was confronted with two problems: (1) that of the machinery of international arbitration, namely, of setting up an international arbitral tribunal; and (2) that of obligatory arbitral settlement. With regard to the latter the progress achieved by the conference was purely nominal. With regard to the former, the convention adopted detailed provisions for the establishment of the Permanent Court of Arbitration.

In a sense, the expressions "court" and "permanent" were misnomers, for it was provided that the Permanent Court of Arbitration should consist of a panel of arbitrators appointed by the contracting parties, each party appointing not more than four members. In case of a dispute which the parties were willing to submit to arbitration, they could—though they were not obliged to—select a number of arbitrators from the panel thus set up. In addition, the convention established the International bureau which was to serve as the registry for the court, to have the custody of its archives and to control its administrative business. Finally, the convention established the Permanent council of the court to consist of the diplomatic representatives of the contracting parties accredited to the Netherlands and the Dutch minister for foreign affairs, who was to act as president of the council. Its task was to control the International bureau of the court and to decide on questions of administration relating to the business of the court.

At the second Hague conference in 1907 an attempt was made to set up a body—an arbitral court of justice—in the nature of a permanent international tribunal as distinguished from a panel of arbitrators. That attempt failed, largely because of the insistence of Latin-American states, ably led by Ruy Barbosa, the delegate of Brazil, on the full observance of the principle of equality in the composition of the court. (*See* also HAGUE CONFERENCES. Between 1902 and 1914, 14 cases were decided by tribunals acting under the aegis of the Permanent Court of Arbitration. Between 1914 and 1932, six cases were submitted to the tribunals of the Permanent Court of Arbitration. No case came before it after 1932. But the Permanent Court of Arbitration was formally still in existence at mid-century and the national groups on the panel of arbitrators had been assigned a—somewhat nominal—function in the procedure of the election of the judges of the International Court of Justice.

Among the notable cases decided by the Permanent Court of Arbitration were the Venezuelan Preferential case (1904), which grew out of the pacific blockade of the ports of Venezuela by Great Britain, Germany and Italy in 1902, the Casablanca case (1909), which resolved a ticklish diplomatic episode between France and Germany, the famous North Atlantic Coast Fisheries case (1910), which resolved a century-old dispute between Great

Britain and the United States concerning fishing rights off the Canadian coast, the Norwegian shipowners' claims (1922), which grew out of the requisition by the United States of ships and shipbuilding contracts in World War I, and the Island of Palmas case (1928), between the United States and the Netherlands.

The Permanent Court of Arbitration is an institution of long history and great prestige. It is flexible in character and enables parties to select their own judges for the settlement of their disputes and to determine the law which such judges shall apply. Proposals have been made that its procedures be re-examined with a view to strengthening and revitalizing it.

Other notable arbitrations which took place in the 20th century included the Venezuelan arbitrations of 1903, the British-American claims arbitrations under the convention of 1910, the numerous cases decided by the mixed arbitral tribunals established under the peace treaties following World War I, the several claims arbitrations against Mexico growing largely out of the revolutionary disturbances of 1914–20, though also including other types of claims, as well as a number of territorial disputes; *e.g.*, between Colombia and Venezuela (1922), Chile and Peru (1925), Mexico and France (1933) and Guatemala and Honduras (1933). A post-World War II arbitration involved the Italian-United States Conciliation commission under the treaty of peace of 1947, which was created to settle, among other things, disputes in connection with the restitution or restoration of the property of U.S. nationals in Italy.

International Judicial Settlement.—Before and during World War I there was a widespread feeling that considerations of international peace, of the development of international law and of a proper administration of international justice required the establishment of a permanent international tribunal. The development of international judicial settlement as a process distinct from international arbitration is discussed in the article INTERNATIONAL COURT OF JUSTICE. A statute for such court was approved by the council and assembly of the League of Nations and was opened for acceptance by states on Dec. 16, 1920.

Obligatory Arbitration and Obligatory Judicial Settlement.—It is a rule of international law that, in the absence of any express undertaking to the contrary, no state is obliged to submit its disputes with other states to arbitral or judicial determination. The relevant articles of the Hague conventions on the pacific settlement of international disputes of 1899 and 1907 are clearly, though indirectly, expressive of that legal position. They provided as follows: "In questions of a legal nature, and especially in the interpretation or application of international conventions, arbitration is recognized by the signatory Powers as the most effective, and at the same time the most equitable, means of settling disputes which diplomacy has failed to settle." It was not until 1903 that international practice registered a treaty of obligatory arbitration—a treaty substantially qualified by far-reaching reservations. This was the treaty between Great Britain and France which provided, in article 1, as follows: "Differences which may arise of a legal nature, or relating to the interpretation of treaties existing between the two contracting Parties, and which it may not have been possible to settle by diplomacy, shall be referred to the Permanent Court of Arbitration established at The Hague by the Convention of 29 July 1899, provided, nevertheless, that they do not affect the vital interests, the independence, or the honour of the two contracting States, and do not concern the interests of third Parties." Before World War I more than 100 treaties of that type had been concluded. Attempts to introduce a more substantial measure of obligatory arbitration as between Great Britain and the U.S. failed because of the insistence of the senate that, notwithstanding the treaty of obligatory arbitration, the submission of any particular dispute to arbitration should depend on the affirmative advice and consent of the senate.

With the creation of the Permanent Court of International Justice, however, essentially a new process was introduced into international jurisprudence. This was the process of international adjudication characterized by a permanent or established court, whose membership was determined by the parties to the statute instead of the parties to each dispute, an administrative secretariat known as the registry, a fixed body of procedural rules, as well as rules for decision, and, finally, as a result of numerous decisions, a jurisprudence. The obligatory jurisdiction of the court under article 36 of its statute meant that for the first time in international practice a court had jurisdiction; that is to say, disputes of a fixed character could be unilaterally submitted by one party to the court for decision, even if the other party were unwilling. Such a unilateral power existed whenever both parties had adhered to the optional clause of article 36, reading as follows:

> The states parties to the present Statute may at any time declare that they recognize as compulsory *ipso facto* and without special agreement, in relation to any other state accepting the same obligation, the jurisdiction of the Court in all legal disputes concerning:
> (a) the interpretation of a treaty;
> (b) any question of international law;
> (c) the existence of any fact which, if established, would constitute a breach of an international obligation;
> (d) the nature or extent of the reparation to be made for the breach of an international obligation.

Development of the Process of Arbitration.—The growth of the process of international arbitration, apart from the process of international judicial settlement, proceeded along two principal lines:

First, as a result of the numerous arbitrations, there developed a technique of procedure consisting of the formulation of procedural rules governing the submission and argument of cases. These were increasingly of a flexible character, varying in accordance with the needs of the particular case or cases. These also developed a considerable body of case law relating to procedure and evidence.

Second, a certain body of obligatory jurisdiction developed, at first along the lines indicated at the outset of this article, by distinguishing legal from political disputes and providing for the obligatory settlement of legal differences or claims of right as distinguished from differences involving vital interests or matters of domestic jurisdiction. The difficulties of interpretation involved in such clauses led to a new approach in the General Act for the Pacific Settlement of International Disputes of Sept. 26, 1928, readopted in the Revised General Act for the Pacific Settlement of International Disputes of April 28, 1949. The General act extended to "disputes of every kind." Arbitration of a dispute, however, was not required until it had been proved impossible of settlement by diplomacy or by the procedure of conciliation outlined in the General act. The General act made it possible for a tribunal to be created even where one of the parties did not co-operate in its constitution.

Notwithstanding these developments, states proved reluctant to submit differences of major importance to arbitration. Even where they had previously agreed in principle to arbitrate, there was the difficulty of implementing such an agreement. The weaknesses implicit in the consensual nature of the arbitral process were dramatized in the dispute between the United States, on the one hand, and Bulgaria, Rumania and Hungary, on the other, arising out of the treaties of peace of 1947. By these treaties disputes arising thereunder, which had not previously been settled as provided therein, were to be referred to an arbitral tribunal composed of one representative of each party and a third member selected by mutual agreement, or, failing such selection by mutual agreement, designated by the secretary-general of the United Nations. A dispute arose between the parties but Bulgaria, Hungary and Rumania each refused to appoint their respective representatives to the arbitral tribunals. The matter was referred to the International Court of Justice for an advisory opinion which decided, in 1950, among other things, that the failure of said countries to name their representatives did not create a power in the secretary-general to nominate the third member. Hence, a two-member tribunal, composed of the representative of the United States and the member to be appointed by the secretary-general, could not be created to hear the dispute. The International Court of Justice held that the defaulting parties were without legal justification in asserting that no dispute under the treaties of peace existed, yet their failure to carry out their legal obligation

to arbitrate the dispute blocked any settlement.

The above incident concerned a failure to carry out an agreement to arbitrate. In other instances, as, for example, in the famous Chamizal arbitration award of 1911 between the United States and Mexico, states have refused to carry out awards finally rendered, on the ground they were void. Such a failure to carry out an award is a matter which should itself be arbitrated rather than be left to constitute an impasse between the parties. The Orinoco Steamship Company case (1910), between the United States and Venezuela, decided by the Permanent Court of Arbitration, was an illustration of the arbitration of a difference as to the binding character of an award. Yet there were a number of instances in which states refused to accept awards as binding and there let the matter stand. The foregoing and other weaknesses of the process of arbitration led the International Law commission of the United Nations, in its Draft Convention on Arbitral Procedure, to endeavour to make the international arbitral tribunal a truly judicial institution.

The Draft convention insisted that once a written undertaking to arbitrate a dispute shall have been made, nothing shall impede the carrying out of the agreement. The Draft convention remedied the defect which led to the above-noted dispute between the United States and Bulgaria, Hungary and Rumania by providing that, if a party shall fail to make the necessary appointments of arbitrators, the tribunal shall be constituted by other means. If a party shall agree to arbitrate but fail to enter into an agreement containing the necessary provisions for the creation of a tribunal to decide the dispute, such an agreement or *compromis* may be drafted by others and will be binding. Proceedings may be held in the absence of a party and a default judgment or award rendered. The tribunal may not refuse to give an award on the ground of "the silence or obscurity of international law or of the *compromis*." Claims of nullity of an award may be referred to the International Court of Justice, subject to time limitations.

The reception of the Draft convention by governments and the general assembly of the United Nations indicated a general tendency to reject the draft. States still generally adhered to the view that arbitration should not be recast into a mold approximating international adjudication and that it should be flexible. States should still remain masters of the agreement, the procedure and the selection of judges.

Other Types of Arbitration.—The arbitration of disputes between states and foreign subjects or between subjects of different states in the sphere of foreign investment or international trade also has been termed international arbitration, though the more usual term is international commercial arbitration. Such arbitration has often been administered through the International Chamber of Commerce or the American Arbitration association. It represents a means for a quick, efficient and economical solution of controversy in the field of international business. Some of such arbitrations even have a place in international jurisprudence, such as the Lena Goldfields arbitration with the U.S.S.R. (1930) and the Trucial Coast arbitration with the sheikh of Abu Dhabi (1952). A United Nations Conference on International Commercial Arbitration was held in 1958 on means for increasing the effectiveness of this form of arbitration.

ARBOGAST (d. A.D. 394), barbarian soldier of the Roman empire, the first to establish a Roman nominee of his own as puppet emperor, was perhaps of Frankish nationality. Having risen to the rank of *magister equitum* ("master of the horse") in the Western Roman army, in 380 he was sent by the emperor Gratian to assist the Eastern emperor Theodosius (*q.v.*) against the Goths in Thrace. He remained with Theodosius, who in 388 sent him to help the child Valentinian II (*q.v.*) against Magnus Maximus in Italy. On the defeat of Maximus, Arbogast was sent to Gaul to remove Maximus' son Flavius Victor and his adherents. In 389 he pacified the Rhenish frontier, imposing a treaty on the Frankish leaders Marcomer and Sunno, who had invaded Gaul in 384.

By 391 Arbogast was all-powerful in Gaul as *comes* (count) or regent; and when Valentinian, on a visit there, tried to dismiss him Arbogast declared that only Theodosius had power to do so. Shortly after this, on May 15, 392, Valentinian died at Vienne in circumstances indicative of suicide but suggestive of murder at Arbogast's behest. Arbogast then proclaimed the rhetorician Eugenius as emperor in the west and set about the restoration of paganism. Arbogast conducted a successful campaign against the Ripuarian Franks, the Chamavi and the Chatti on the right bank of the Rhine in the winter of 392–393; but in May 394 Theodosius marched against him to suppress the pagan revolution. The battle of the Frigidus river (the Vipacco or Wippach, a tributary of the Isonzo) began on Sept. 5 and ended next day in victory for Theodosius. Eugenius was killed, and Arbogast fled to the mountains, where he committed suicide two days later (Sept. 8, 394). Arbogast was a great general and an energetic statesman. His pagan revival was inspired by admiration for the Roman republic and by contempt for the quarrels of Catholic and Arian Christians.

ARBOR DAY, an annual tree-planting day generally observed throughout the United States. It originated in Nebraska, where it was first observed on April 10, 1872. The plan of devoting a certain day each year to the public planting of trees and the name Arbor day were proposed by J. Sterling Morton, then a member of the state board of agriculture and later U.S. secretary of agriculture. In 1885 Arbor day was made a legal holiday in Nebraska, and thereafter a number of states made similar enactments. At first the efforts to extend its celebration were made chiefly through agricultural associations and town authorities, but about 1882 the plan of making it a school festival was inaugurated. As such, the observance of Arbor day spread throughout the United States and far beyond its borders. Moreover, its scope and purpose were greatly broadened. From simple exercises and the planting of single trees to beautify public grounds, it became the occasion for impressing upon the minds of school children the importance of forestry and for the planting of seedling trees to reforest otherwise waste lands.

The time of celebration varies in different states, sometimes even in different localities in the same state. An effort was made by the National Arbor Day commission to establish a unified national observance on the last Friday in April, and a number of states observe this date. Another organization, the Arbor Day association, incorporated in 1956, performed extensive Arbor day promotion throughout the United States.

ARBORETUM, a place where trees and shrubs are cultivated for ornamental, scientific or other educational purposes; it is that portion of a botanical garden devoted to woody plants. An important characteristic of an arboretum is that all plants are adequately labeled, with at least common and scientific names and continent of origin. Thus an arboretum is a living dictionary of trees and shrubs, referring to where the species were originally found growing wild. In the 20th century practically all botanical gardens are also arboretums, so the names are commonly used interchangeably. Arboretums are sometimes maintained by individuals on private property, or they may be publicly owned, occasionally being developed within an existing city park. More frequently they are set up as independent institutions with or without municipal or other governmental support. Some high schools, colleges and universities have developed their grounds as arbore-

tums for the general public as well as for student use.

The trees and shrubs are usually arranged by plant families, *i.e.*, all members of the pine family are placed in one section of the tract, the maple, oak, willow, rose, linden, heath, olive and other families are grown in their own special areas. Some arboretums arrange their collections ecologically, others according to geographic origin of the species—so one may see miniature landscapes of plants representing different parts of the world. Others arrange plants according to economic or aesthetic use. In the second category, for example, are hedge displays, where many different kinds of shrubs and trees are planted in separate rows and clipped to demonstrate hedges for all tastes and locations.

Europe.—As early as the middle of the 16th century René du Bellay of Touvoys, in co-operation with Pierre Belon, made a fine collection of trees and brought into France seeds of exotic species from western Asia. This collection long remained the richest and most beautiful in France and perhaps in the world. About 1720, Duhamel du Monçeau, head of the French marine and a scientist, gathered plants from all over Europe and North America to set out on his two estates. The plants were arranged systematically in what might be called the first arboretum made for scientific purposes. From his experience with the collection, Monçeau published in 1755 a book on characteristics and cultivation of trees and shrubs which had a great influence on study and early distribution of imported plant species.

One of the most complete arboretums in the world is that at Kew, Eng., in the Royal Botanic gardens. It traces its origin (1759) to a 9-ac. private garden on the estate of Princess Augusta. This garden, together with the adjoining garden of Richmond lodge, occupied by her son George III, was turned over to the nation in 1841. Other tracts were added later. The first director was Sir William Hooker, who was succeeded by his son, Sir Joseph. The arboretum occupies a large portion of the entire tract, with trees and shrubs representing about 10,000 species and varieties. In addition to the arboretum at Kew, other important collections of trees and shrubs in the British Isles are to be found at the Royal Botanic garden in Edinburgh, the gardens of the Royal Horticultural society at Wisley, and the Irish National Botanic gardens at Glasnevin, Dublin. On the continent of Europe the classical example is the formally designed Jardin des Plantes in Paris.

North America.—Most arboretums in the United States were founded by amateurs. For example, Henry Shaw, a businessman, in 1859 founded and endowed what later became the Missouri Botanical garden in St. Louis. The special arboretum section of this institution is 38 mi. from St. Louis, at Gray Summit. In 1922 Joy Morton, then president of the Morton Salt company, founded and endowed the Morton arboretum in the Chicago suburb of Lisle. Similarly, Pierre S. du Pont founded and developed Longwood as his private estate near Wilmington, Del. Upon his death in 1955 it was left, richly endowed, as a public garden and arboretum.

Among other better-known arboretums in North America are the Arnold arboretum, Jamaica Plain, near Boston, Mass. (1872); Boyce Thompson Southwestern arboretum, Superior, Ariz. (1924); Brooklyn Botanic garden, Brooklyn, N.Y. (1910); Dominion Arboretum and Botanic garden, Ottawa, Can. (1886); Highland and Durand-Eastman Park arboretum, a part of the park system of Rochester, N.Y. (1890); Montreal Botanical garden, Montreal, Can. (1932); National arboretum, Washington, D.C. (1927); New York Botanical garden, New York city (1895).

In temperate climates many arboretums offer a series of dramatic floral displays during the flowering season with forsythia, flowering cherry, flowering crab apple, dogwood, lilac and other beautiful ornamentals. In the fall and winter, unusual species such as witch hazel, franklinia, heather, etc. are often featured.

Function in Scientific Research.—In addition to their role in public education, arboretums may have such objectives as follow, a number of which involve scientific research:

1. To grow as wide a selection of plants of quality as is possible in a particular climate. This often means the introduction and testing of plants not previously known or grown in a certain area. If space is limited, only the most ornamental and reliable plants are given preference. For instance, the major objective of the Arnold arboretum for many decades was to introduce and test new species of trees and shrubs from temperate climates all over the world. The best of these were released to nurserymen for propagation and ultimate sale to the public.

2. To breed new types of trees and shrubs, using the basic collection as parent stock. Objectives in such breeding work might include resistance to pests and diseases, greater hardiness, earlier or later flowering, double flowers, dwarfness, better foliage quality, etc. Breeding trees of economic importance may lead to more rapidly growing and disease-resistant varieties.

3. To study and taxonomically describe and classify species and varieties of ornamental trees and shrubs. This means building up a technical reference collection of dried plants, called an herbarium. From this, books such as Alfred Rehder's *Manual of Cultivated Trees and Shrubs* are written, so that persons everywhere may have ready access to authoritative works.

To carry on these programs, arboretums need experienced plant propagators, gardeners, botanists and horticulturists. Adequate funds are needed; as mentioned, some arboretums are supported by endowment income. Others are membership societies supported by payment of dues; still others are supported entirely from tax funds. In the case of the New York and Brooklyn botanic gardens, annual appropriations by the city of New York supply part of the funds, and the balance comes from membership dues, special gifts and income from endowment.

The public generally looks upon an arboretum as a fine park, a place to go for recreation and to increase one's knowledge about nature. The aesthetic role has gradually assumed greater importance. In addition to special lectures and conducted tours through the plant collections, many arboretums have excellent reference libraries and act as centres of plant information, identifying plants sent in by amateurs, answering questions and publishing bulletins.

ARBORICULTURE is the cultivation and care of woody plants, particularly trees and shrubs used for decorative, shade and ornamental purposes. In arboriculture the welfare of the individual plant is given prime consideration, in contrast to such related fields as silviculture and agriculture where the well-being of a group of plants as a whole is the major concern. (*See* FORESTS AND FORESTRY; FRUIT FARMING; ARBORETUM.)

Early Egyptians are credited with being the first people to transplant trees with a ball of earth and originating the practice of shaping the soil around the newly planted tree to form a saucer to retain water. The Greek philosopher Theophrastus about 302 B.C. wrote *On the History of Plants*, in which he discussed transplanting of trees and treatment of tree wounds. Roman knowledge of tree culture is portrayed in Virgil's *Georgics*. In his *Sylva, or a Discourse of Forest Trees*, dated 1664, the English horticulturist John Evelyn (*q.v.*) offered advice on pruning, insect control, wound treatment and transplanting. Arboricultural principles and objectives are of ancient origin; only techniques, materials and methods of application have changed.

Essential to success in the practice of arboriculture is a clear understanding of tree growth processes, and of the role played in a tree's development by climate, soil conditions and other external influences. The arborist (one who practices arboriculture) must have a good working knowledge of plant physiology, soil science, insects and diseases that affect woody plants, chemistry insofar as it pertains to the use of fertilizers, growth regulators, antibiotics, insecticides, fungicides and other chemical compounds applied to plants and proficiency in the mechanical arts. Skill in selecting plants and grouping them for their ornamental values as well as for their hardiness and pest-resistant qualities certainly

is desirable. (*See* also Landscape Architecture.)

The arborist's work includes transplanting, pruning, applying fertilizer, spraying to control insects and diseases, cabling and bracing, tree wound treatment, tree removal, cavity treatment,

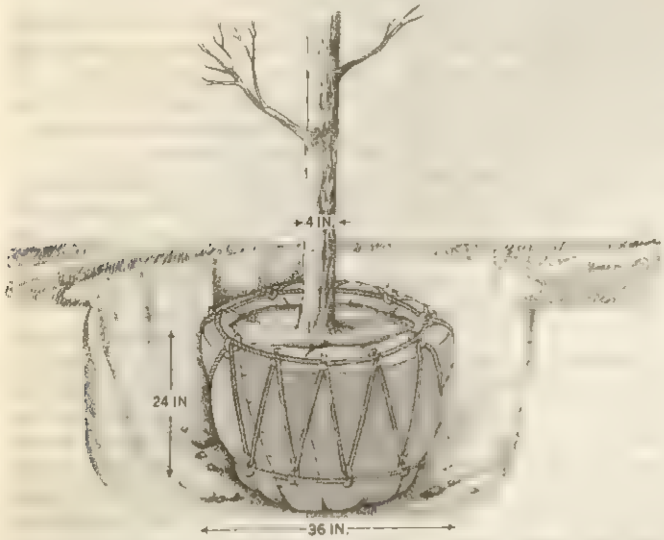

FIG. 1.—TRANSPLANTING DECIDUOUS TREE WITH ROOTS BALLED AND BURLAPPED. SURFACE MEASUREMENT OF BALL VARIES WITH THE SPECIES BUT IS ROUGHLY NINE TIMES THE DIAMETER OF TRUNK OF TREE MEASURED AT ONE FOOT ABOVE GROUND LINE; DEPTH OF BALL IS ROUGHLY SIX TIMES THE DIAMETER OF TRUNK

identification of plants, diagnoses of tree ailments, tree damage appraisals and numerous miscellaneous activities which relate to trees and shrubs.

Transplanting.—Deciduous trees (those that drop their leaves annually) usually are transplanted during the period that extends from the time they drop their leaves in the fall until new leaves appear in the spring. The spring period for planting evergreens usually begins about the time deciduous trees are coming into leaf and continues for a month; evergreens may be planted also in late summer or early fall. Most small deciduous trees may be moved "bare root," with no soil attached to the root system; those greater than about three inches in trunk diameter are best moved as "balled and burlapped" stock in which a ball of earth, held in place with burlap, encloses the roots. Evergreens of size suitable for home planting are balled and burlapped before moving.

Holes for planting should be dug of sufficient depth and width to permit natural spread of the roots, or to receive the ball in the case of balled and burlapped stock. The tree should be planted to approximately the same depth it stood at the time of digging. Planting should be done as quickly as possible after digging; meanwhile, the roots should be kept moist and protected from the sun and wind. The planting hole should be backfilled with fertile soil of good texture; it should be worked in around the roots and tamped to eliminate air pockets. A shallow saucerlike depression should be formed around the tree to retain water. After planting is completed the tree should be thoroughly watered. Usually it is good practice to guy the tree to prevent wind sway, and to wrap the trunk with burlap or similar material to prevent sun scald.

Pruning.—The pruning of a shade or ornamental tree is done to protect its health, improve its appearance and remove hazards to life and property. Pruning includes removal of old branch stubs and broken, dead or diseased branches; cutting back of limbs that interfere with traffic, impede electric service, obstruct desirable views or mar the tree's characteristic symmetrical shape; thinning to permit air circulation and secure more light; removal of branches that rub against other limbs to prevent wounding and possible future decay problems; judicious cutting to compensate for root loss, promote blossom formation, restore a storm-damaged or unshapely tree to its normal form and, occasionally, heading back to revitalize an aged tree. Each tree normally assumes a shape and form characteristic of the species; care should be used in pruning to avoid destroying the natural growth pattern.

Pruning of most deciduous trees may be done at any time of the year. Maple, birch and a few other species may "bleed" (exude sap) copiously if pruned in late winter or spring; this is unsightly though it causes little or no harm to the tree. Pruning of evergreen trees that bear needlelike leaves usually should be confined to removal of dead wood. In evergreen shrubs the tips of branches are clipped back to induce compact growth. In pruning back the branches of shrubs or young trees, the cut generally is made just above a healthy bud or immediately beyond a lateral branch. In mature trees long unpruned, two or more moderate prunings usually are better for the health of the tree than a single severe pruning.

No branch stubs should be left in pruning. Even a short stub seldom, if ever, is healed over with new wood growth before it decays and by that time the wood-rotting fungi may have penetrated deep into the tissues of the tree. The pruning cut should be made flush with, and parallel to, the stem from which the branch is being removed.

The removal of large, heavy branches is a three-step operation. First, an undercut is made with the pruning saw a foot or more beyond the point of the final cut. Next, the limb is severed with an overcut and usually lowered to the ground by means of ropes. Finally, the stub is removed. Removal of heavy branches with a single cut is likely to result in bark and wood being stripped from the stem below the cut as the branch falls. Tree wound dressing, available at most horticultural or garden supply stores, should be applied to all cuts greater than one inch in diameter.

Use of Fertilizers.—Different trees vary in their responses to fertilizers. Fertilizer is used beneficially to maintain or restore soils to a high level of fertility, or to stimulate new growth and vigour after a tree has suffered injury from insect or disease attack, drought, severance of roots, lightning strike, wind and ice storms.

Commonly, fertilizer used for trees contains nitrogen, phosphorus and potash in proportions of 12-6-4, 10-8-6 or a similar mixture. Frequently used is a 10-8-6 mixture in powder form. Generally recommended rates of application are three to five pounds per inch of trunk diameter for deciduous trees above six inches in diameter and one-half that amount for smaller trees and evergreens. The fertilizer is introduced into the soil that surrounds the roots by means of a punch bar, air pressure or water jet. Following application the area is watered to carry the material to the roots. Completely soluble fertilizers are available for foliage spraying, and these are used with good results. Shade trees generally benefit from applications made at intervals of one to three years, the time varying with the species of tree and growth response.

FIG. 2.—PRUNING SMALL TWIGS: (A,B,C,) INCORRECT CUTS: (A) TOO SLANTED, EXPOSING HEARTWOOD, (B) TOO LONG, ENCOURAGING ROT; (C) TOO SHORT, INTERFERING WITH BUD GROWTH; (D) CORRECT CUT

Spraying to Control Diseases and Insects.—Leaf-spotting fungi, which cause unsightliness or defoliation of shade and ornamental trees, often make spraying or dusting necessary. Sycamore, elm, ash, juniper, spruce, hawthorn and mountain ash are but a few of the ornamental trees that are sprayed to prevent disease. In general, there is less need for spraying shade trees as a protection from fungus attack than there is for insect control. Numerous fungicidal materials are available for use in spraying.

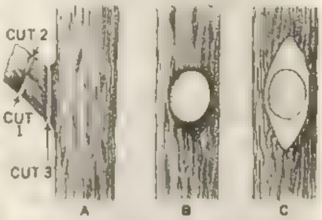
Insects may be classified according to the type of damage they cause—leaf-eating, sap-sucking and burrowing. Leaf-eaters may be controlled by use of stomach poisons, such as the arsenicals, or with such materials as DDT which may serve as both a stomach and a contact poison. Sap-sucking insects, of which aphids, scale insects and plant lice are examples, are controlled only with contact insecticides such as miscible oils, nicotine sulfate or certain

of the organic compounds developed after World War II. A number of the organic compounds are quite effective in control of leaf miners and stem or trunk borers.

On the containers of insecticides available at retail stores are given directions for use, rate of application and usually a list of the insects the material will control. In all insect control, it is of the utmost importance that the insecticide be applied at the time in the life cycle of the insect when it is most vulnerable. This necessitates a broad knowledge of entomology.

Preventing and Repairing Damage.—Under certain conditions artificial support is of distinct benefit to shade trees. Such support, supplied in the form of flexible cables or rigid braces, is needed when trees develop narrow, structurally weak V-shaped branch crotches; when splitting occurs at branch forks; and when unduly long, pendulous branches develop. Cables or guys also may be used to lessen the danger of a mature tree with a weakened root system being blown over by wind, and to support recently planted trees until the roots become established.

In trees with structurally weak, but unsplit crotches, cables are installed as a means of protection against storm damage. Location of the cables is based on the principles of the lever and fulcrum; they are placed as high in the tree as practicable, usually about two-thirds of the distance from the crotch to the branch tips. The cables are attached to the branches by means of lag screw hooks, hook bolts or eyebolts. Cables should never be wrapped around a branch since this restricts the sap flow and may cause death of the limb.



FROM P. P. PIRONE, "TREE MAINTENANCE"; OXFORD UNIVERSITY PRESS, NEW YORK (1959)

FIG. 3.—PRUNING LARGE BRANCH OF TREE OR SHRUB: (A) POSITION AND SEQUENCE OF CUTS; (B) FRONT VIEW AFTER FINAL CUT; (C) CUT WITH BARK TRIMMED AND TAPERED TO FACILITATE PROPER HEALING

In repairing split crotches, a block and tackle is used to pull the branches together until the split closes. Then holes are drilled through the split parts and a screw rod, or sometimes bolts and nuts, are installed. Usually, additional support is provided by installation of cables as described above. Screw rods or bolts and nuts are used to fasten together two major branches that rub against each other. A single rod through the branches at the point of contact will hold them rigidly together thereby eliminating rubbing and consequent wound formation.

Trees may be invaded by fungi that cause decay of the heartwood and the development of large cavities in the trunk. This results in a weakening of the structural strength of the tree and it becomes vulnerable to the twisting strains of wind storms. To compensate, in some measure at least, for the strength of the internal woody tissues lost through decay and to hold the cavity walls in position, rigid cross braces are installed. Difference of opinion exists concerning the filling of cavities. Many arborists favour open cavity treatment in which the decayed wood is removed, the inner walls treated with antiseptic dressing materials and drains installed at the bottom of the cavity. Other arborists favour filling the cavity with concrete or other materials after removal of the decayed wood. Cavity filling seldom is advocated in short-lived or weak-wooded tree species.

Treatment of Tree Trunk Wounds.—Damage to tree trunks in the form of large areas of bark torn away through impact is of frequent occurrence. In treatment of such wounds, loosened bark along the sides of the wound is trimmed back to the sound tissue. To facilitate healing, the bark at the top and bottom of the injury also is trimmed back forming a pointed ellipse of the wound area. The exposed wood is then covered with wound dressing material to protect the tree from invasion by wood decay fungi.

Tree Propagation.—In a broad sense the term arboriculture includes not only care of established trees and shrubs, but also propagation of plant materials. This is the process by which plants are reproduced from the parent stock by means of seeds, layering, cuttings, grafting or budding. Such work usually is performed by nurserymen, plant propagators or specialists skilled in this phase of plant culture.

Seeding.—Sometimes direct seeding is practiced in which the seed is planted on the site desired for the tree. This method is especially suited to such trees as hickory, walnut and other taprooted species which may be injured by ordinary transplanting techniques. More often, however, seeds are planted in either a commercial or a home nursery where intensive care can be given the young plants for several years or until they attain a size suitable for transplanting. Seedbeds are prepared as carefully as in gardening and the seeds sown by broadcasting or with a seed drill. A mulch of leaves, straw or marsh hay may be used to protect newly sown seedbeds, especially if the seeds remain in the ground a long period before germinating or if the young plants are of a species that grows slowly. Shading evergreens and some deciduous species from the sun during the summer months is often necessary. The amount of shade needed depends upon the species and local weather conditions.

Layering.—The shoots or lower branches of many plants when partially covered with soil will form roots while still attached to the parent plant. Propagation by this method is known as layering. The stem is bent down so that a section rests in a previously dug shallow trench with the branch tip extending beyond the trench. The section in the trench is then covered with moist soil of good quality. A brick or other weight may be used to hold the soil-covered branch section in place. When roots have developed, which may require from several months to a year or more, the branch is severed from the parent and transplanted. The new plant retains all the characteristics of the parent. This method is used frequently to obtain independent plants from a tree with historical associations.

Air Layering.—In this method of propagation a branch is slit deeply or girdled, and the wounded section enclosed in a ball of earth, moss or similar material which must be kept constantly moist. This rooting medium may be held in place by a divided pot supported from below, stout paper shaped in the form of a cone or other means. As in soil layering, the branch is severed and transplanted after roots have developed.

Root Cuttings.—Some trees rarely produce roots from stems, but can be propagated by root cuttings. Roots are cut into pieces several inches long and planted horizontally in moist soil, moss or sand flats. When tops and roots develop they are lifted and transplanted.

Stem Cuttings.—Cuttings from stems are made from both deciduous trees and evergreens, although it is usual to reproduce most conifers and many hardwoods from seed. Pines, for example, do not ordinarily grow from cuttings, but can be made to do so by the use of growth-promoting substances. Untreated cuttings of arborvitae and juniper usually root satisfactorily. Tree species that tend to sucker or send up shoots readily, such as willow and poplar, frequently are propagated from stem cuttings. Privet and the evergreen species of holly often are propagated in this manner.

Stem cuttings are made from deciduous plants during dormancy and, preferably, from the terminal growing shoots of the current season. Pieces usually are cut six to ten inches in length, generally with two or more buds on each piece. The cuttings are tied in bundles, stored in damp sand or moss for callus formation, and then planted in prepared beds. Abundant watering is necessary. In cuttings made from conifers, two- to five-inch shoots are obtained and the foliage removed from the lower part. Usually they are planted at once in flats of moist sand under cover, often in a cool greenhouse, where they remain until roots form sufficiently for transplanting.

As mentioned, root formation may be stimulated by the application of certain chemicals, known as growth-promoting substances or growth hormones. Indoleacetic and indolebutyric acids, for example, are employed for this purpose.

Grafting.—There are certain trees which, if grown on their own roots, are especially susceptible to root diseases, insect attack or adverse soil conditions. Rootstocks of different species therefore are used to propagate these plants, as well as to produce generic variations (mutations and bud sports) with peculiar characteristics which may not root readily.

Grafting is the introduction of a part of one plant into or onto the living part of another plant in such a manner that the two will unite and continue their growth as a composite individual. A woody shoot bearing one or more buds (scion grafting) may be used or, in budding, one bud only with a small area of bark is inserted in contact with the cambium (growing layer) of the "stock." If the top of a plant is replaced by shoots or buds from another plant, the tree is said to be "top-worked." In general, plants must be botanically related for successful grafting (*see* GRAFTING [IN PLANTS]).

ARBORVITAE (TREE OF LIFE), the common name for evergreen trees or shrubs of the genus *Thuja*. *Thuja* comprises a genus of four to six species belonging to the cedar or cypress family (Cupressaceae).

Thuja occidentalis is the eastern arborvitae or northern white cedar of eastern North America and ranges from Canada to the mountains of North Carolina and Tennessee. The tree attains a height of 40 to 50 ft. and features scalelike leaves borne in flattened sprays; when bruised they exhale an aromatic odour. In its many dwarf horticultural varieties the eastern arborvitae finds wide use as an ornamental in rock gardens, foundation plantings and borders.

BY COURTESY OF U.S. FOREST SERVICE

EASTERN ARBORVITAE (THUJA OCCIDENTALIS), BRANCH WITH CONES

The giant arborvitae or western red cedar (*Thuja plicata*), is a native of western North America. It attains gigantic proportions in the forests along the Pacific slope, where it is often 150 to 200 ft. tall and 5 to 10 ft. in diameter. The wood is exceedingly durable and is used for shingles, siding, poles, posts and mine props.

Another species of arborvitae is *Thuja orientalis*, known also as *Biota orientalis*. The latter generic name is derived from the Greek adjective *biotos*, formed from *bios*, "life," probably in connection with the name "tree of life." This is the Japanese hiba or Chinese arborvitae. It was cultivated in the Chelsea Physic garden in 1752, and was believed to have been sent to Europe by French missionaries. It has roundish cones, with numerous scales and wingless seeds. The leaves, which have a pungent aromatic odour, yield a yellow dye. There are numerous varieties of this plant in cultivation, one of the most remarkable being *pendula*, with long, flexible, hanging, cordlike branches. The variety *pygmaea* forms a small bush of only a few inches in height. (E. S. HR.)

ARBROATH, a royal burgh and seaport of Angus, Scot., 17 mi. N.E. of Dundee by road or rail, lies at the mouth of Brothock water (the old name of the town was Aberbrothock). Pop. (1961) 19,533. Area 2.3 sq.mi. The ruins of the red sandstone abbey, once the richest in Scotland, stand in High street. It was founded by William the Lion in 1178 for Tironensian Benedictines from Kelso, and consecrated in 1197, being dedicated to St. Thomas (à) Becket. It was William's only personal foundation and he was buried within its precincts in 1214. There the Scottish parliament met on April 6, 1320, to send the pope the notable letter asserting the independence of their country and reciting in eloquent terms the services which their "lord and sovereign" Robert the Bruce had rendered to Scotland. An annual historical pageant is held in the abbey. Arbroath was created a royal burgh in 1186 and its charter of 1599 is preserved. The harbour, originally constructed and maintained by the abbots, by an agreement in 1394 between the burgesses and John Gedy the abbot, was enlarged in 1725 and 1844 and the old part made into a wet dock in 1877 when the entrance to the new harbour was deepened. There is a lifeboat station and the lighthouse on the Bell rock (*q.v.*) or Inchcape lies 12 mi. S.E. in the North sea.

Arbroath is the "Fairport" of Sir Walter Scott's *The Antiquary*. Hospitalfield, ½ mi. W., once the abbey hospice, and the "Monkbarns" of the novel, is an art school with a collection of Scottish art. The parish church dates from 1570. The Old Red Sandstone cliffs, weathered into weird shapes and caves, form part of the coastline and were once used by smugglers; the beaches are sandy. Auchmithie, 3 mi. N.E. ("Mussel-crag" of *The Antiquary*), is a picturesque old fishing village. At church St. Vigeans, 1 mi. N. of Arbroath, is the Drosten stone, thought to be the only sculptured stone in Scotland with a legible Pictish inscription. The church, founded in the 11th century and restored, contains Celtic sculptured stones, some of which were incorporated into the walls. Arbroath's main industries are textiles, flax spinning, the making of canvas, sailcloth and bleaches, engineering and ironworks, shipbuilding, fishing and canning, and tourism.

ARBUTHNOT, JOHN (1667–1735), Scottish mathematician and physician chiefly remembered as a friend of Jonathan Swift, Alexander Pope and John Gay. He was born at Inverbervie, Kincardineshire, in April 1667, and, after the death of his father in 1691, went to London where he taught mathematics. He entered University college, Oxford, in 1692, and in 1696 became M.D. at St. Andrews. He published *An Essay on the Usefulness of Mathematical Learning* (1701)—a plea for greater emphasis upon mathematics in the university curriculum—became a fellow of the Royal society in 1704 and was one of Queen Anne's physicians from 1705 until her death in 1714. After the queen's death he continued to have a distinguished practice and to publish essays on medical topics. He also published an important work on numismatics, *Tables of Ancient Coins, Weights and Measures* (1727). He died in London on Feb. 27, 1735.

With the exception of a meditative poem, *Know Yourself* (published anonymously in 1734 and later as *Know Thyself*) Arbuthnot's literary works are all satirical. The most important fall into two groups. The first consists of five pamphlets first published separately and later under the composite title *The History of John Bull* in 1712. This is an extended political allegory somewhat in the manner of Swift's *Tale of a Tub* although without Swift's elaborate digressions and complexity of irony. The chief actors in the events which led up to the treaty of Utrecht are caricatured as Lord Strutt (Charles II of Spain), Lewis Baboon (Louis XIV), Nicolas Frog (the Dutch) and John Bull (the English). John Bull, "in the main . . . an honest plain dealing fellow, choleric, bold, and of a very unconstant temper," is a national hero here clearly defined for the first time. In the simple but effective action he is very nearly tricked by the duplicities of the other national heroes and by the self-centredness of Humphrey Hocus the attorney (the duke of Marlborough).

The other satire in which Arbuthnot had an important share was *The Memoirs of . . . Martinus Scriblerus*, first published in the 1741 edition of Pope's works, but largely written as early as 1713–14 by the members of the Scriblerus club, whose most important members were Arbuthnot, Swift, Pope and Gay, and which aimed to ridicule bad literature and false learning. The *Memoirs* were designed, in Pope's words, "to have ridiculed all the false tastes in learning, under the character of a man of capacity enough, that had dipped into every art and science, but injudiciously in each." The result is a biography which gives full scope for a mocking exposure of pedantry and false learning. The work was consistently undervalued, largely because of a lack of suitable editions until 1950 when it was edited by C. Kerby-Miller. *The History of John Bull* was edited by H. Teerink in 1925.

See G. A. Aitken, *The Life and Works of John Arbuthnot* (1892); L. M. Beattie, *John Arbuthnot, Mathematician and Satirist* (1935). (JN. C.)

ARBUTUS, a genus of evergreen trees and shrubs of the heath family (Ericaceae) characterized by smooth, red, exfoliating bark, handsome foliage, showy flowers in terminal clusters and attractive, red, berrylike fruits. There are about 12 species, found chiefly in the Mediterranean region, Central America and western North America. In mild climates several species of *Arbutus* are planted for their beautiful foliage, flowers and fruit. Of these, the best known is the strawberry tree (*A. unedo*), a native of southern Europe and Ireland. The Pacific madrone (*A. menziesii*), a handsome tree of the west coast of North America, is sparingly transplanted. The trailing arbutus or Mayflower (*see* ARBUTUS, TRAILING) of eastern North America belongs to a different genus (*Epigaea*), also of the heath family. (E. S. HR.)

ARBUTUS, TRAILING (*Epigaea repens*), a fragrant flowering plant of the heath family (Ericaceae), also called Mayflower, common in rocky woods and on hillsides from the Maritime provinces in Canada to Florida and westward to Minnesota. The flowers appear as early as April, while the snow still lingers, and are eagerly sought as one of the first signs of spring. In regions near towns they are often stripped from the woods by ruthless persons and also sold on street corners. The plant stems are tough and sturdy, rough-hairy, and creep close to the ground under the dead leaves of the preceding season. The old leaves are rusty, dull green and heavily midveined. New leaves develop in June, rough in texture with fine netted veins and paler on the lower surface than on the upper. The small nectar-bearing flowers, which exist in four forms, are white to pale pink and delicately scented, five-lobed and tubular, and grow on stems 6 to 12 in. in length.

TRAILING ARBUTUS OR MAYFLOWER (EPIGAEA REPENS)

ARC, ELECTRIC: *see* ELECTRICITY, CONDUCTION OF: *The Arc;* LIGHTING: *Electric Lamps, Electric Discharge Lamps, Arc Lamps, Gaseous Vapour Lamps;* FURNACE, ELECTRIC: *Arc Furnaces;* WELDING: *Arc Welding.*

ARCADE, in architecture, a series of arches assembled in a single composition, particularly when the arches are of approximately the same size and placed upon the same level. Arcades are used structurally as in the arcade between the nave and aisles of a church, which supports the clerestory wall and the nave roof. They are also used, purely decoratively, where a band of horizontal decoration is required. Although the arch was known to many of the peoples of antiquity, it was the Romans who first appreciated its decorative possibilities and who made it, again and again, a dominant feature of great architectural importance, as in the Tabularium and in any Roman amphitheatre. An arcade, such as those used by the Romans, with the front face of each pier ornamented by a pilaster or engaged column that carries an entablature running over the tops of the arches, is known as a Roman arcade, and was a favourite motive of the Renaissance. During the late Empire, the Romans started to build arcades whose arches were carried directly upon the capitals of a range of columns (*e.g.*, the great court of the palace of Diocletian at Spalatro), and during the Romanesque and Gothic periods this became the normal type, although in the Byzantine work of the eastern empire, spreading blocks, known as impost blocks, were often placed between the capitals and the arches.

Arcades were used decoratively, to a great extent, in north Italian Romanesque. Some fronts, such as that of the cathedral at Pisa, consist entirely of rows of freestanding arcades. In the medieval architecture outside Italy (except for the Romanesque churches on the Rhine, where Italian influence is strong) decorative arcades were almost always actual parts of the wall and are known as wall arcades. The word arcade is also used, at the present time, to designate any covered passageway on which shops open. (T. F. H.; H. MN.)

ARCADELT, JAKOB (*c.* 1500–*c.* 1570), an early master of the madrigal, was a native of Flanders. His first publication dates from 1532 (Lyons). He probably went to Italy about 1538, and became a singer and later choirmaster at the Sistine chapel in Rome in 1539, resigning in 1545. In 1547 he returned after a year's absence in France, leaving again before 1552. He was serving Charles, duke of Guise, in 1555, and by 1557 he was a member of the French chapel royal. He vanishes from the records about 1567, and died before 1572.

Arcadelt's fame rests on about 120 chansons and over 200 Italian madrigals. With Costanzo Festa and Philippe Verdelot, he set the style for a generation of madrigal-composers. He favoured four-voiced composition, and his secular music owes much to the simple declamation and tuneful treble of the *frottola*. Cipriano da Rore and Palestrina both learned much from Arcadelt's limpid clarity. He published about 20 motets, three Masses, six books of madrigals and a collection of chansons.

BIBLIOGRAPHY.—Modern editions of his music, largely secular, may be found in R. van Maldeghem's *Trésor Musical* (1874, 1884 and especially 1889–92; madrigals); *Publikationen der Gesellschaft für Musikgeschichte*, ed. by R. Eitner, vol. 23 (chansons); A. Einstein, *The Italian Madrigal*, vol. 3 (1949); E. B. Helm, *The Chansons of Jacques Arcadelt*, vol. i, in *Smith College Archives*, no. V (1942) (42 chansons). The well-known *Ave Maria* is a near-forgery dating from 1845, when P. C. P. Dietsch arranged the top part of a three-voiced chanson of 1554 as a sacred piece. *See* also R. Eitner, "Jakob Archadelt," in *Monatshefte für Musikgeschichte* (1887); W. Klefisch, *Arcadelt als Madrigalist* (1938). (B. L. TR.)

ARCADIA (mod. Gr. ARKADHÍA), in ancient Greece, was the central district of the Peloponnesus, bounded on the north by Achaea, on the south by Messenia and Laconia, on the east by Argolis and on the west by Elis. Ancient Arcadia was thus cut off from the coast on all sides, and is therefore not exactly coextensive with the modern *nomos* (department) of Arkadhía (area 1,664 sq.mi., capital Tripolis) which extends on the east to the Gulf of Argolis (formerly Nauplia). The inland plateau of Arcadia is bounded in the north by the Erymanthus (Erimanthos) and Cyllene (Killíni) mountains and is itself divided by numerous subsidiary ranges. In eastern Arcadia these enclose a series of plains drained only by underground channels. The western country is more open, with isolated mountain groups and the winding valleys of the Alpheus (*q.v.*) river and its tributaries the Ladon (Ládhon), which is harnessed for electric power, and Erymanthus (Erímanthos). Isolated geographically from the rest of Greece, Arcadia was not occupied by the Dorians when they invaded Greece in the 12th century B.C., and retained a dialect strongly resembling that of the Greeks who had settled in Cyprus. When, however, the power of Sparta grew, the Spartans could not neglect Arcadia. Unable to force their way through Argolis, they needed to control Tegea (*q.v.*) and the other Arcadian towns to secure their passage to the isthmus of Corinth. By 550 B.C. the Arcadians had all accepted Spartan leadership and alliance but whenever Sparta showed weakness there was potential danger from Arcadia. At some date during the period 475–460 when their influence was on the wane, the Spartans had to fight a combination of Arcadians at Dipaea and from 420 to 418 Athens was allied with Argos, Mantinea and Elis. However, the rivalry of Tegea and Mantinea normally prevented concerted action.

After the battle of Leuctra (371) (*q.v.*), a political league grew out of an old religious synod, and a federal capital was founded in a commanding strategic position at Megalopolis (*q.v.*). But a severe defeat by Sparta in 367 (the "tearless battle" in which no Spartan lives were lost) and internal discord paralyzed this movement. During the Hellenistic age Megalopolis stood staunchly by Macedonia; the rest of Arcadia rebelled against Antipater (331, 323) and Antigonus II Gonatas (266). Thereafter the cities divided their allegiance between the Achaean and the Aetolian leagues, and submitted, some to Spartan and others to Macedonian influence. In Roman times Arcadia fell into decay. An influx of Slavonic settlers in the 8th century A.D. checked depopulation, but Arcadia suffered severely from the constant quar-

rels of its Frankish barons (1205–1460). Turkish rule combined with Albanian immigration raised the prosperity of the land, but in the War of Greek Independence the strategic importance of Arcadia once more made it a centre of conflict.

The pastoral character of Arcadian life together with its isolation partly explains why it came to be represented as a paradise in Greek and Roman bucolic poetry and later in the literature of the Renaissance.

Bibliography.—B. V. Head, *Historia Numorum*, 2nd ed. (1911); E. C. Semple, *The Geography of the Mediterranean Region* (1932); J. A. O. Larsen, *Representative Government in Greek and Roman History* (1955).

ARCADIA, a residential city of southern California, U.S., within the metropolitan area of Los Angeles, is near the eastern end of the San Gabriel valley. Once part of Rancho Santa Anita, Arcadia was developed by Elias J. ("Lucky") Baldwin in the 1880s and became a boom town like its neighbours, Monrovia and Sierra Madre. Incorporated in 1903, Arcadia was noticed early for its live oak, eucalyptus and pepper trees, and its orange and lemon groves. Tourists often visited the 54,000 ac. Baldwin estate with its rare shrubs and artificial lakes. Later reduced in size, the estate (Los Angeles State and County arboretum) is maintained as a public park. Santa Anita race track is in the western part of the city. For comparative population figures *see* table in California: *Population.* (J. A. Sz.)

ARCADIUS (Flavius Arcadius) (*c.* 377–408), Roman emperor from 383 to 408, was the elder son of Theodosius I and Aelia Flaccilla. Born before his father became emperor, he was still a child when Theodosius proclaimed him as emperor in the Hebdomon at Constantinople on Jan. 16, 383. When Theodosius left for Italy in 394 to engage the pagan usurper Eugenius, Arcadius remained in Constantinople as ruler of the east; and when Theodosius died in the west in 395, Arcadius became sole emperor of the east. A small, weak, irritable and stupid youth, he rarely exercised any influence, and the history of his reign is largely the history of the ministers who dominated him in turn. The first of these was the prefect Rufinus, in whom Theodosius had had full confidence and whom he left in the east in 394 to advise and guide Arcadius; but Rufinus was murdered late in 395, probably at the instigation of Stilicho (*q.v.*). The second of Arcadius' ministers was the eunuch Eutropius, on whose advice he had married Eudoxia (on April 27, 395, before his father was buried). She bore him Flaccilla in 397, Pulcheria in 399, Arcadia in 400 and, on April 10, 401, his only son, Theodosius, whom he proclaimed as the emperor Theodosius II on Jan. 10, 402, to rule the east jointly with himself. Eutropius was executed at the end of 399; and Arcadius' next powerful minister was Anthemius, an able administrator of whom little is known. The reign was marked by the devastation of Greece by Alaric (*q.v.*) in 395–396; by the revolt of the Gothic troops under Gainas in Asia Minor in 399–400, crushed only after Gainas had held control of Constantinople for six months; and by the banishment of the patriarch of Constantinople, John Chrysostom. Throughout most of the reign relations with the Western empire were strained because of the competing claims of both governments for the possession of the prefecture of Illyricum.

See J. B. Bury, *History of the Later Roman Empire*, vol. i (1923); E. Demougeot, *De l'Unité à la division de l'empire romain, 395–410* (1951). (E. A. T.)

ARCESILAUS (315/314–241/240 b.c.), Greek philosopher, from Pitane in Aeolia, succeeded Crates as head of the academy in Athens, to which he, with obvious preference for Plato's early dialogues, gave an antidogmatic turn, thus revolutionizing or, as others assert, restoring genuine Platonism (*see* Academy, Greek). Criticizing the Stoics, he denied the existence of sense-presentations evidently and adequately "grasping" reality, to which alone the ideal wise man would unfailingly assent. Consequently, he advocated the "withholding of assent" (*epoche*) in all cases; whether as an ultimate goal, is controversial. His profession of ignorance ("I am ignorant even of my ignorance") exceeded that of Socrates. In matters of conduct, he said, the wise man will be satisfied if he can defend his action as having been "reasonable" (*eulogon*). Arcesilaus left no writings. (Pr. M.)

ARCHAEOLOGY (ARTICLES ON). Interest in archaeology ranges widely; at one extreme is the amateur relic hunter or antiquarian; at the other lie a humanistically oriented concern with the material traces of man, especially the Greek, Roman and Bible-land civilizations, and a more general anthropologically oriented concern with the course of cultural evolution. The article Archaeology summarizes the history, changing methods and goals of the field itself and presents a survey of the results of archaeological research in the various regions of the world, beginning with an account of human cultural evolution during prehistoric times. Before recorded history, in most parts of the world, various means of food-producing through the domestication of plants and animals had been achieved (*see* Agriculture: *World Agriculture;* Animals, Domestication of) and the technological and economic foundations for civilizations had been set. Urban civilization was first to appear in southwestern Asia about 3500 b.c., and various starts were made, subsequently, in other parts of the world (*see* City).

The archaeology of various areas of the world, where it is significantly understood, is given in separate articles (*e.g.*, Indonesian Archaeology and Art; Babylonia and Assyria; Andean Civilization) or in the archaeological sections of articles on continents, regions (*e.g.*, Oceania; Asia Minor) and nations (*e.g.*, Egypt; Iran; Greece; Rome). Again, where there is sufficient clarity in understanding, the more important of the extinct cultures are given separate entries (*e.g.*, Aegean Civilization; Anasazi; Hallstatt; La Tène; Indus Civilization; Hopewell; Etruscans; Maya Indians; Aztec; Sarmatians).

Finally, various specific types of archaeological artifacts or monuments (*e.g.*, Flint and Other Stone Tools; Lake Dwellings; Obelisk; Mummy; Pyramid), and of arts and technologies that first appeared in the archaeological past (*e.g.*, Metalwork, Decorative; Pottery and Porcelain; Primitive Art; Astronomy) should be studied.

Archaeology deals with the reclamation and interpretation of the material traces of man's past. Since man is intractable and often disorderly, his traces are bound to turn up in odd places and under peculiar headings. Reference to the Index is thus advised. Archaeologists have much in common with anthropologists, art historians, general historians, and philologists; and are aided by (and often aid) such natural scientists as agronomists, botanists, chemists, geologists, paleontologists, nuclear physicists, and zoologists (*e.g.*, *see* Radiocarbon Dating; Geochronology; Monuments, Preservation of). The generalizations of anthropology and particularly of social anthropology (*qq.v.*) are of increasing interest to modern archaeologists. For other areas of major concern to archaeological science *see* Alphabet; Ecology; Jewelry; Man, Evolution of; Music, Primitive; Music in Ancient Civilizations; Numismatics; Paleography; Papyrology; Medicine and Surgery, History of.

Ancient man was quite like his modern counterpart. Had he not involved himself in so many different activities, it would be much easier to categorize his traces. (R. J. B.)

ARCHAEOLOGY. Archaeology is that science or art—it can be maintained that it is both—which is concerned with the material remains of man's past. There are two aspects to the archaeologist's concern. The first of these is the discovery and reclamation of the ancient remains; this usually involves field excavation or at least surface collecting. The second concern is the analysis, interpretation and publication of the findings.

To the lay mind, the archaeologist is often a romantic figure who spends his time discovering hidden cities or royal tombs full of gold and precious stones. In actuality, the professional archaeologist spends most of his time in the classification and interpretation of unspectacular and repetitious objects of little or no aesthetic appeal or monetary value. But without the analysis and, especially, the interpretation of his recoveries, the archaeologist's work is without real meaning or reason.

The materials of archaeology are both the things made by man and the things used by man. The things made by man are the settlements, buildings, utensils, tools, weapons, objects of ornament

or pure artistic expression—the sum total of things fashioned in some way for human purposes. A general term for any one of the things made by man is artifact. The nonartifactual materials which were used—but not made or fashioned—by man are the unworked bones of the animals which he ate, the traces of the plants either grown or collected for food, the charcoal from ancient hearths—all the things utilized by man as given by nature.

Both the artifactual and the nonartifactual materials have their important roles in archaeological interpretation.

Strictly speaking, archaeology is not concerned with the analysis and interpretation of the bones of ancient man himself—whether fossilized or not. The study of the skulls and skeletons of ancient man is the concern of the physical anthropologist or human paleontologist. Neither is the archaeologist normally prepared to decipher or interpret the writings of ancient man—this is the specialty of the epigraphist and philologist.

The present article is divided into the following sections:

I. INTRODUCTION

General History and Development.—The ancients themselves—when digging holes in the ground for one reason or another—sometimes encountered the traces of preceding cultures and made observations and deductions which might be called archaeological. Up to about the 18th century, however, artifacts were more usually thought to be the tools of dwarfs and witches, if the artifacts were noticed at all. Only a few rare minds, such as that of Leonardo da Vinci, can have had any notion as to the natural human origin of artifacts. It is curious that Thomas Jefferson may be called the first scientific digger. He excavated Indian mounds in Virginia, kept careful notes of his observations and drew conclusions from them.

In terms of the history of ideas, it would appear that one of the two major approaches to archaeological thought arose within the great humanistic tradition of the Renaissance. Part of the reviving interest in classical Greece and Rome was a concern with the art and architecture of the Greeks and Romans. Sculpture, pottery and coins were collected, and excavation was undertaken (albeit primarily for the purpose of sales to private collectors). With the creation of the great national museums of Europe—for example, the Louvre as a public institution at the time of the French Revolution—a need for materials to fill their exhibition halls came into being.

At this point it is convenient to see the humanistic approach to archaeology as composed of two branches: a fine arts or museums branch and an academic or scholarly branch. In actuality, the early practitioners did not make such an explicit subdivision. The early British and French expeditions to Mesopotamia were frankly collecting enterprises, but Napoleon's even earlier scientific commission in Egypt had both collecting and scholarly interests.

Given the philosophical orientation of its initiators, the humanistic approach to archaeology has tended to restrict itself to Greece, Rome and, by natural extension, to their provinces and to the Bible lands. With rare exceptions (generally concerned with an artistic expression comprehensible or exciting to the western mind) the humanistic approach has concerned itself only with the earlier manifestations of the western cultural tradition. The exceptions may also include—especially in the countries of western Europe—interest in national origins: of France with the Gauls, Great Britain with the Britons, Germany with the early Germanic tribes, etc.

The second of the two major approaches to archaeology appeared about the middle of the 19th century. It might be called the approach of the social sciences—most characteristically, of anthropology. It arose as part of the magnificent burst of activity in the natural sciences, of Charles Darwin, Thomas Henry Huxley and the great geologists. Stimulated by the thought of such men as Lewis Henry Morgan and Sir Edward Tylor, the early anthropologists reasoned that if there were a process of biological evolution, then why not a process of social evolution as well? Hence the concern of the early ethnologists with finding "living fossils" among the isolated societies of remote places, and of the anthropological archaeologists with the recovery of traces of extinct societies which would fit into a developmental scheme of social evolution.

The matter did not prove to be as simple as the early social evolutionists anticipated. However, part of their importance is that they gave rise to an approach and a way of thinking with which the humanists had no interest. The "exotic," the "peripheral," the very remote peoples—whether living or dead—were of little or no concern to the humanists but a delight to the anthropologists. Anthropological archaeology, too, developed both museum and research scholarly branches in its approach.

In their extremes, the attitudes of the two main approaches have been harmful to what must be their common goal—a fuller understanding of mankind. Both the humanistically and the scientifically oriented archaeologists developed a kind of professional snobbishness, which tended even to discourage their curiosity about what was being learned in the other camp. Fortunately—especially from about 1930—this snobbishness has been disappearing.

The present article is a case in point: with the world of the past as a stage for the article, the contributors necessarily represent scholars from both the humanistic and the anthropological approaches. It will be obvious that their interests (and what they stress as important in their respective sections) are often different. By and large, however, there is either explicit or implicit in their writings a concern with the man behind the artifact.

The Great Problems Approached by Archaeology.—If it is agreed that archaeology's major concern is an understanding of mankind in the past, that archaeology is the only means of examining extinct human cultures and achievements until written records become both profuse and meaningful, then certain problems come into focus. Whether oriented toward the humanities or the sciences, the colour of the museum man's interest in these problems tends to differ somewhat from that of his research-scholar colleague. It will also be understandable, in terms of the philosophical history of its interest, that humanistic archaeology is concerned mainly with the fourth and fifth of the six general problems listed below. These six general problems, which probably encompass all of the legitimate interest of archaeology, are:

1. How may we understand the emergence and development of man, or, more properly, of a toolmaking and culture-bearing manlike being?
2. How may we understand the appearance of anatomically modern man and the cultural florescence which seems to attend his appearance?
3. How are we to understand the origins of food production and the rise of an effective village-farming community?
4. How did civilization, manifesting itself archaeologically as a more

or less urbanized and politically formalized society, with public projects and monumentality in art and architecture and usually with writing, make its appearance; how shall we understand certain apparent regularities held in common by the independent original civilizations?

5. How are we to understand the nature of the early (not so profusely literate) civilizations as they differ from or resemble the later historical or modern civilizations, and what were the mechanics of cultural transmission and of cultural change in their time?

6. Given the enormous time depth with which only archaeology is prepared to deal, what can we learn of the changing relation between man, society and culture on the one hand and environment on the other; what of the generalized cultural processes (diffusion, invention, acceptance, rejection, etc.), which, because of the bearing of this time factor, can be examined in no other way? For the related set of problems within this general heading, it would not matter whether civilization proper ultimately had been achieved or not.

It goes without saying that we take "understand," as used above, also to mean "to appreciate the meaning of, and thereby to benefit in, human understanding."

Order of Incompleteness of the Archaeological Record.—The sections which follow suggest the state of understanding on the six general problems of archaeological concern early in the second half of the 20th century. A serious hindrance to full understanding is, of course, the incompleteness of the archaeological record. The archaeological record would be fully complete only if every artifact, and all nonartifactual material, used by man since his beginning was already recovered in a well-preserved condition and was ready for interpretation. There being no possibility of such completeness, it is wise to inquire into the relative order of incompleteness of the record.

A primary notion in archaeology is that of context, *i.e.*, the original find spot of an artifact, ideally the place in which the artifact was last used by man. Context also has implications of an association of artifacts, from simple objects of daily use clustered about their original hearth to the vast complex of associations at, for example, Pompeii. The context is as much a part of the archaeological record as is the artifact itself. If precise observations as to horizontal and vertical (stratigraphic) position and associationship are not made, the artifact is contextless. Thousands of contextless artifacts exist, some having been separated from their original find spots by natural agencies—usually geological weathering or erosion—but many also being contextless because of the depredations of amateurish or avaricious "relic hunters." A large part of the exacting mechanics of professional archaeological field excavation in surveying, photography and notation is above all an attempt to record context.

An associationship of artifacts and nonartifactual materials, from a given context, suggests the notion of the archaeological assemblage. The assemblage consists, ideally, of everything made and used by an extinct culture; it is the mail-order house catalogue plus, the entire physical manifestation of a way of life and the true basis for an archaeological interpretation of an extinct culture. The difficulty is, of course, that so many items in any assemblage have a low survival value. Objects of baked clay, stone, bone and some of the metals preserve well; the softer materials usually disappear in large part, save under very favourable natural conditions (as, for instance, in Egypt or coastal Peru). It is with the preservation of any possible trace of the more perishable categories that more of the exacting mechanics of professional field techniques are concerned, and there is a heartening increase in new methods for the reclamation of materials once thought to have been completely perishable.

The human element itself also modifies the relative completeness of the record in two ways. First, some ancient cultures seem to have been—unwittingly, of course—more considerate of archaeology than were others. The elaborate funerary interests of the Egyptians played into archaeologists' hands; so, for example, did the Swiss lake dwellers' habit of building their houses on piles in a lake where anything dropped overboard became waterlogged and well preserved.

The second human element is the archaeologist himself. The discipline in the latter half of the 20th century was still new, and field techniques were only beginning to become professionally exacting. Archaeology, unfortunately, from its beginning tended to attract dilettantes and sensation seekers as well as true culture historians; some of the former have been intelligent but others bumbling and even actually destructive. Different from the physical and biological sciences, an experiment in archaeological excavation can never be repeated or even very exactingly checked by professional colleagues. Charlatans—and there have been a few—can probably continue unexposed for a longer time in archaeology than in any other profession. Also to be accounted for within the human element category are some of the extremes of both the humanistic and the social science branches of the profession, the extremes of some of the national "schools" of archaeology, and inadequate and subjective publication of results.

In sum, while the archaeological record is incomplete, it is not discouragingly so. As the discipline grows in professional stature, and as new techniques in observation and reclamation are developed and utilized, the trend is toward greater completeness of the record. It is unfortunate that the early pioneers chose the best available sites—one could learn more from these sites now, even more in the future—but archaeology has had to learn from past mistakes in more ways than one.

Archaeological Classification and Terminology.—Artifacts of archaeological interest are available in the hundreds of thousands and nonartifactual specimens certainly in the thousands. It has proved necessary to develop schemes of classifying these materials for convenience in study and interpretation. Once detailed classificatory schemes involving objects from proper archaeological contexts are made, it is sometimes possible to introduce contextless materials into the scheme on the basis of analogy alone.

Classifications based on the materials of which artifacts were made, and on the techniques of manufacture, are probably less useful in detail than are those based on form and imputed use. However, gross subdivisions of archaeological assemblages are usually made in terms of materials; *e.g.*, clay, stone, bone, metal, wood and so on. With the aid of various analytical techniques (chemical, petrological, etc.) such gross classifications most closely approach objectivity, and the same is true to a somewhat lesser extent of classifications based on original technique of manufacture. In fact, these two kinds of schemes blend together, as technique of manufacture was generally adapted to a particular type of material. It is in these categories that the archaeologist is most dependent on the natural scientist and his analytic procedures.

For purposes of drawing cultural interpretations from a given assemblage, classifications based on form and imputed use of materials are more interesting. They are also, usually, more subjective. It is one thing to have a metallurgist make an exact assay of the metal in a bronze tool, but quite another thing to describe, on the basis of the form of the tool, exactly what its original use may have been. This kind of difficulty becomes even more acute as technology grows more complex and exotic forms become possible. For example, as objects of supposedly religious or other nonutilitarian significance begin to be manufactured, their exact interpretation may become less certain. This is even true of essentially utilitarian forms which become culturally significant. A modern example would be a gold-plated trowel used in laying the cornerstone of a public building; it is simply a trowel in form, but its real function is loaded with overtones of cultural tradition which would not be immediately apparent to the archaeologist.

A further complication, especially with classifications based on form and imputed use, is the idea of the type object. With hundreds or even thousands of roughly similar objects to classify and describe, the archaeologist usually must select a type to represent a whole class of objects. The choice of this type or model or representative of a whole class is conditioned by the relative completeness of the record (how large a series does the class contain?), by preservation factors and by the discernment and interests of the typologist. It is obvious that the selection of a type object must always be more or less subjective.

Terminology in archaeology never has been (and probably never will be) completely standardized. Difference in interests

generally leads individual archaeologists to idiosyncratic preferences in the terminologies they use. By and large, four factors enter into terminological usage: locality, time, description and interpretation. Such a phrase as "the Old Stone Age of Britain" (or substitute for "Old Stone" "Paleolithic," which is simply its Grecized form) indicates locality, "Britain"; time, "Age," with an imputation of a time long ago when only stone tools were made or used; description, "Old Stone," with an imputation of crude stone tools alone; and interpretation, which is rather implied than expressed in the total phrase, which carries the general meaning of a stage of cave-dwelling savagery.

Unfortunately, in much of the archaeological literature up to the 1940s, and even in some thereafter, the four factors are more often confused than clearly delineated by the terminology. The use of the Grecized forms—Paleolithic, Mesolithic, Neolithic, Chalcolithic, etc.—has often allowed archaeologists to appear to write learnedly but without precision in meaning. The words are not necessary. Robert J. Braidwood, for example, did a little book on *Prehistoric Men* without the use of any of the Grecized terms, and no reviewer even commented on the fact.

It is usually easy enough for an archaeologist to express the notion of locality, although the original area of distribution of an assemblage may not yet be fully known. Precision as to the time factor in years before the present becomes increasingly possible as detailed understanding of geological and radiocarbon chronologies increases. General descriptive names for assemblages of artifacts tend to be simply the adjectival form of the place name of the site where the assemblage was first examined; for example, the well-made flint hand ax or bifacial tool first noted at St. Acheul in France is generally referred to as "Acheulean," regardless of where it is now found. Interpretative terminology tends to reflect general stages of culture—a stage of cave-dwelling savagery, a stage of simple village-farming communities, a stage of incipiently urban market-town communities, a stage of an essentially urban political state.

Professional Archaeology.—Most of the great European and American universities are prepared to offer higher degrees in professional archaeology. It is rare that the archaeologist is considered professionally "finished" without the Ph.D. degree; curriculums leading to such a degree in archaeology exist in both the humanistic and the social science disciplines. A sound general education and ability to operate in the languages of scholarly communication (English, French, German; if necessary, Spanish or Russian) are the basis for the graduate curriculums. Since the concern of archaeology is with man and his works, the breadth of an archaeologist's general education is of the greatest importance.

Professional archaeologists hold posts in the larger universities and museums and in the establishments of the various national schools abroad—for example, the British School of Archaeology in Athens. In the United States, archaeologists are also employed by the national park service, by the state museums and historical societies in some of the states, and in some of the river basin reclamation programs. Other countries also have archaeologists in their own equivalent services.

As a general rule, archaeology in Great Britain and in Europe has tended to be supported by the state. In the United States, some government and state support is available within the boundaries and territories of the country only, and most archaeology has been privately supported, with private grants being made to interested universities and museums. With the tax structure as it existed during and after World War II, private support tended to diminish, though it was supplemented to a degree by support from the learned foundations. (*See* ARCHAEOLOGY, SOCIETIES OF.)

Archaeology and Society.—There is no practical justification for archaeology which would have immediately satisfied Sinclair Lewis' George Babbitt. It can be justified on a philosophical level, as can history, as part of man's apparently natural curiosity about his own past. It can also be justified, as can anthropology, as an attempt to gain an objective and scientific understanding about mankind itself.

Both the philosophical and the scientific factors do suggest, however, in what ways concern with the past may be quite practical. In his book, *Archaeology and Society*, Grahame Clark has examined the way in which in some countries man's curiosity about his past has been consciously manipulated to further national and political ideologies. It could be maintained that it is the responsibility of the intelligent citizen to understand the nature of the archaeological record, its relative order of completeness and the basis for the drawing of archaeological interpretations.

In the latter half of the 20th century, while there was an enormous amount still to be learned about the past, it could be comfortably asserted that there were no longer any grand archaeological rabbits still to be pulled from the hat of time. One might be suspicious of assertions about mysterious but otherwise unspecified movements of "peoples from the north," about still hidden "cradles" of mankind (or of "civilization"), about lost continents of Atlantis or Mu. Modern archaeology had passed beyond this stage; it already knew that such things as "pure races" or "pure cultures" are myths. It had passed its pioneer stage, and was settling down to the very difficult and detailed task of understanding a very complex and very interesting being—man himself.

II. THE MATERIALS OF ARCHAEOLOGY

Excavation.—Archaeology or prehistory, the science that studies the history of human culture through its material remains, is limited to analysis of those items (and inferences drawn therefrom) which have escaped the destructive forces of decay. Wherever man has altered the natural surface of the earth, as at a site where people have lived, some evidence will remain, and with the proper method of detection such spots can be identified. Usually the archaeologist concentrates his field activity at a spot where intensive or long-term human activity has occurred, for there is the location most productive of the information for which he is searching.

Archaeological sites may be of several sorts. Closed sites such as caves may on occasion be so well protected from the weather that otherwise perishable objects made of wood, basketry or leather may be perfectly preserved. In the western United States, for example, are numbers of such dry caves which have produced large quantities of well-preserved organic materials, and the complete preservation of some tomb contents of dynastic Egypt are well known. In northwestern Europe a large number of remains, either of individual objects or burials or of whole sites, have been found in peat deposits. Organic materials tend to be preserved nearly as effectively in the moist, acid conditions of peat as in completely dry caves. Most prehistoric sites are in the open and consequently are subject to the influences of climatic and geologic forces which cause the disintegration, covering or erosion of evidences of former occupation. Trash mounds, formed by the gradual accumulation of refuse, occur very generally where man has settled for any length of time. In coastal regions such sites so commonly take the form of shell mounds (kitchen middens), so named because their bulk is largely composed of shells of mollusks once used for food. Fire hearths, floors of houses, storage pits, lost and discarded tools, bones of food animals and all the miscellaneous by-products of living commonly occur in such trash heaps. Cemeteries where the dead were buried usually occur in the proximity of occupation sites. Megalithic or other stone or earth structures such as temples, dolmens, barrows, fortifications, ditches, roads and pyramids may be particularly obvious remains of man's former presence. Other sites may be in the form of cave walls bearing pecked petroglyphs or painted petroglyphs (petrographs) such as the famous Upper Paleolithic (Magdalenian) caves at Altamira, Spain, and Lascaux, France. This general type of aesthetic expression occurs widely in all continents. Mines and quarries where flint or obsidian, soapstone, building stone, coloured pigments, iron or copper ore, etc., were extracted are widespread and are evidence of early industrial pursuits. Even ancient garden plots can be located, as proved by aerial surveys

in the British Isles.

In addition to material objects made by man, food remains in site deposits may enable a reconstruction of economic pursuits and provide some indication of the relative importance of fishing, hunting, gathering or farming. Trade, travel and intergroup contacts can often be reconstructed by identifying the material or forms of certain objects as made in some region far distant from the spot where they are recovered by the archaeologist.

The aim of the field archaeologist is to recover as much material as possible or necessary for the interpretation or reconstruction of the former culture pattern. Since archaeology means systematic excavation for the recovery of buried materials, the excavator must be acquainted with the techniques of map making, methods of preserving materials which he uncovers and correct procedure in actual digging.

Discovery of archaeological remains may come about through several means. Materials may be exposed through natural erosion, as in the banks of rivers or streams, or by human disturbance, as in ditching, plowing or digging of building foundations. Commonly the field archaeologist is an expert in recognizing surface evidences of man's former presence in the form of a distinctive dark soil colour due to charcoal from fires, irregularities in the normal surface relief, unusual vegetation which is a function of the different soil chemistry of occupation sites, or the presence of exposed artifacts as a result of erosion of the surface.

Once having searched for and found the sites, the archaeologist selects the site to be excavated. Excavation entails careful attention to the placement and association of each object or feature uncovered. Most or all portable objects are saved and removed to the laboratory or museum for study. Nonportable remains such as house floors, stone constructions and the like are recorded in notes and documented in photographs. Bones of animals in refuse layers are collected and identified, and this information may indicate foods used as well as give evidence of the local environmental conditions when the culture was in operation. The association of items in the deposit may assist in determining their original functions; thus, objects found in a ceremonial chamber, in a refuse pit or in a cache of tools may indicate, respectively, that the various items were used for religious, culinary or industrial activities. Full photographic and notebook records of finds and observations are made, and these are utilized in preparing the final report. Some excavations, especially in the Mediterranean and Central American areas, where monumental architecture is notably characteristic, may be performed primarily for the purpose of reconstructing ancient temples or pyramids. In the eastern Mediterranean area extensive digging has been performed for the purpose of identifying sites, structures and cultures mentioned in the Bible. In every case, the particular problem which the archaeologist is attempting to solve determines his choice of sites and method of approach in excavation.

Methods of Dating.—Since archaeology is a historical discipline and concerns the development and succession of human cultures, the problem of dating finds is of fundamental importance. Age assignments may be of two orders: (1) direct or absolute dates; and (2) indirect or relative dates.

Direct or absolute dates can be expressed in numbers of years. Calendrical records in the old world do not carry beyond the last 5,000 years and in the new world not past the beginning of the Christian era. The absolute dating method known as dendrochronology (*q.v.*) works by counting annual rings of trees. Beginning with living trees, the pattern of wide and narrow rings, which reflect conditions of temperature and rainfall experienced during the life of the tree, can be extended backward in time with the use of prehistoric wood samples. This method was developed and carried to its highest point in the southwestern United States, where the tree-ring chronology extends back about 2,000 years. Elsewhere, as in Alaska and the eastern United States, the method has been applied to advantage but without such striking results. The astronomical chronology of F. E. Zeuner, which gives the Pleistocene epoch a duration of about 600,000 years, is based upon calculating the dates of periodic changes in the earth's orbit and axis which are presumed, but not proved, to have affected the amount of solar radiation received by the earth's atmosphere and to have been the cause of Pleistocene glaciation. The Zeuner chronology thus gives "dates" for the four main periods of glacial ice advance and intervening periods of ice retreat (interglacials). Paleolithic implements and fossil human remains which occur in identifiable glacial or interglacial deposits can thus be dated approximately with reference to the Zeuner chronology. It should be noted, however, that extensive criticism has been directed toward the Zeuner chronology. An alternative theory of causes for Pleistocene glaciation has been proposed by M. Ewing and W. L. Donn. Counts of annual sediment layers (varves) deposited by retreating glaciers in northwestern Europe and northeastern North America have yielded a chronology, to which archaeological finds can often be correlated, for the last 15,000 years. (*See* PLEISTOCENE EPOCH.)

Another method of absolute dating is the radiocarbon technique. Mildly radioactive carbon (carbon with an atomic weight of 14) is formed in the atmosphere and is contained in the bodies of all organisms (plants and animals). C^{14} decays or disintegrates at a constant rate, its half life being 5,700 years. Thus, in 5,700 years one-half of the original amount of C^{14} is left, in another 5,700 years one-quarter of the original amount remains and so on until the amount becomes too small to be measurable. The method can be used to date unaltered carbon-containing organic materials such as peat, pollen, wood, ancient charcoal, burned bone, etc., back to about 45,000 years ago. It has not, however, been perfected beyond possibility of error. (*See* RADIOCARBON DATING.)

Relative or indirect dates are expressed relative to some other chronological event. The Pleistocene glacial chronology and paleontological succession of animal forms furnish convenient sequences of events to which Paleolithic culture finds may be referred for relative age determination. The primary chronological tool of the archaeologist is stratigraphy (*q.v.*) or superposition. Unless disturbances of deposits has occurred, the oldest objects will lie near the bottom and the most recent ones near the top. Within any archaeological deposit laid down over a long period of time it is usually possible to indicate changes in type or styles of artifacts from bottom to top. Analysis of stratigraphic series of pollens contained in postglacial lakes or bogs has yielded surprisingly complete information on the sequence of ancient climates and flora which can often be of aid in assigning ages of prehistoric archaeological materials. A method of deriving chronology or sequence from surface materials where stratification is lacking is called seriation. The method was devised in the Zuñi region of the southwestern United States by A. L. Kroeber, who made potsherd collections from the surface of a number of sites. The pottery types showed overlap, so that types A and B at one site could be correlated with B and C at another, and this in turn with C and D at a third site. The seriation from type A to D was clear, and direction of the sequence (either A to D or D to A) was determined by identifying type D with the early historic Zuñi type. The potsherd seriation method of determining space-time relationships was carried further by James A. Ford in the southeastern United States and by workers in Peru.

Typology.—While much of the information derived from excavation can be presented by simple description and illustrated by drawings or photographs, this is not always convenient, since there may be large numbers of specimens which show important individual differences. The usual means of treating large bodies of artifacts is by means of typology (*q.v.*) or classification into classes and types. Classes consist of groups of objects segregated according to material (*e.g.*, artifacts of stone, bone, shell, wood, antler, clay, etc.) and then further segregated into subclasses or types based upon differences of form, function, decoration or technique of manufacture. Classification may be based upon the methods of manufacture, as in the case of Paleolithic stone implements, where shape may have been incidental and the flaking process was the primary concern of the maker. In an effort to make dead archaeological data more significant, some workers employ a functional method of classification, organizing all objects recovered according to their presumed original purpose, so that categories of

the warfare complex, economic and handicraft complex, etc., are established. Within classes of artifacts may be distinguished types such as pottery types which are recognized on the basis of particular combinations of kind of clay, method of firing, colour and style of decoration, shape of pots and the like. Chipped stone projectile points are often typed on the basis of size and form.

When the prehistorian is engaged in analyzing the materials from a single occupation period which may comprise the deposits of an entire site or derive from one stratigraphic level of a site which has been occupied by successive culture groups, he may establish a "culture type." Such culture types are usually named and serve as datum points for comparison with other culture types. Prehistoric cultures may sometimes be associated with an ethnic group, but usually their bearers are anonymous, and cultures are thought of in terms of a characteristic aggregate or constellation of specific artifact types. European prehistorians often use the term industry, by which they mean all the implements found in archaeological context or association in one layer and made of one material (as stone or bone).

Man is a tradition-bound animal. He learns to do things by being taught by the older generation and therefore tends to reproduce the same material or social forms. Changes in evolution and degeneration do occur, but in simpler societies, whose remains are generally those with which the archaeologist is concerned, these changes are more slowly paced and less abrupt than in modern society, in which technological change proceeds at a rapid rate. Through the Paleolithic period a limited number of forms of stone tools were manufactured by the same technique for tens of thousands of years. With the passage of time since man's emergence from the brute state as a toolmaking and fire-using animal, and with the increase of numbers of mankind and consequent growth or elaboration of cultural equipment, the tempo of culture change has also accelerated. The basic assumptions underlying systematic typology are that cultural change will be evidenced in the material objects and that this change is evidenced both in terms of space (geographic spread) and time (chronology).

By mapping the location of sites and determining the geographic distribution of cultures it is often possible to find correlations of culture areas with natural environmental areas, to determine settlement patterns and shifts of population centres through time, and by comparing the local or regional culture sequences to gain insight into culture-historical processes over wider areas. Classification must be meaningful to the archaeologist, for it furnishes him with a scheme for drawing conclusions, and, according to the materials being analyzed and his aims, the prehistorian will elect one or the other of the various methods available.

Cultural Inferences.—Once having performed the labour of excavation and the task of classification, it remains for the archaeologist to treat the historical problem of how the culture he is studying came to constitute the particular aggregation of traits which it displays. Such explanations, which are rarely complete and precise, entail reference to what are called culture processes, the factors operating toward the change, growth or stabilization of cultures. Culture types which are geographically widespread may be assumed to have diffused from one generative centre in the course of time, and the point of origin can often be indicated as the locus where it occurs earliest or in most complex form. Cultural traits or trait complexes are often observed to have discontinuous distributions. If the spatial discontinuity is very large and diffusion from one source is judged improbable, or the temporal placement of the occurrences is markedly different, the archaeologist may conclude that independent or parallel invention explains the multiple occurrences. The cultural parallels occurring on either side of the Pacific have been judged by some anthropologists to indicate transpacific cultural diffusion and by others as explainable in terms of parallel or independent development. Proofs of such alternative explanations can rarely be adduced, and the decision to support one or the other usually rests upon that one on which the student believes the weight of probability to bear most heavily.

Some culture-historical facts or situations can be explained with reference to ecological factors, so that types of culture are sometimes noted to correspond in their distribution to natural or ecological zones. This was well illustrated by Kroeber in his study of late American Indian cultures, where types of native culture are shown not only to conform to climatic, biotic and physiographic factors but also in many instances to have a considerable historical (chronological) depth. American archaeologists who employ the direct historical approach begin by excavating sites known to have been occupied in the historic period by a particular tribe, and from this historic datum then work backward in time through a series of prehistoric sites by means of identifying the specific culture complex in order to trace the historical development of the culture. Clark studied the economic basis of prehistoric European cultures from a historical viewpoint and demonstrated that the various economies, such as sea hunting, land hunting and farming, are conformable to specific biological and physical environments of the past.

Walter W. Taylor argued that space-time problems are not so important as what he termed the "conjunctive approach" or functional interpretation of archaeological data, in which the excavation results are written up in the manner of an ethnography of a living culture by identifying the function of each object, noting intrasite associations and relationships and reconstructing the prehistoric data in terms of function and culture processes. Taylor's argument was effective, and deeper anthropological insight resulted.

The historical-geographic-temporal distribution of prehistoric cultures are sometimes graphically presented in the form of phylogenetic or taxonomic charts, the assumption being that cultures develop in the manner of biological evolutionary radiation. This approach was critically reviewed by John O. Brew in 1946. The synthesization of prehistory into schemes of evolutionary culture stages was attempted by V. Gordon Childe, and a sequential "culture epoch" formulation of wide application was advanced by Julian H. Steward.

The discipline of modern archaeology has been developing from about 1850. During most of this period it was preoccupied with the collection of materials and descriptive reporting of finds. Partly through the stimulus of the strong emphasis on theory in modern social anthropology, archaeologists were beginning to accumulate a systematic body of archaeological theory. Notable contributions to this subject have been made by C. F. C. Hawkes, E. MacWhite and G. R. Willey, among others.

III. PREHISTORY
